Sir **RICHARD DOUGLAS POWELL** opened a discussion on the Action of Medicinal and other Means of Treatment in Cardiac Failure. He said that he would limit his remarks to cases of acute heart failure and would only discuss the mechanism and treatment of three or four of the more important kinds. He gave an instance of sudden death in aortic regurgitant disease, pointing out that the death in this case arose from syncopal failure of circulation in the brain due to failure of the heart during the diastolic period. In a second, an anginoid, variety of cardiac failure in aortic regurgitant disease death was threatened during an attack of vaso-motor angina. But in this condition the mechanism was different, the peripheral vessels were contracted not dilated, and although the strain upon the ventricle unsupported by the aortic valves was very great, still the blood was retained in the arterial capillaries and nerve centres and the syncopal failure of the heart might be delayed until remedies could be applied. These remedies were of the class of nitrites to release arterial spasm, with strychnine and perhaps morphia to support the heart and to relieve pain. Further attacks were to be prevented by looking to the visceral causes of vaso-motor storms and correcting them. Another variety of acute and fatal heart failure was instanced in a man with mitral stenosis who after the relief of urgent symptoms by rest and treatment had gradually been fed up to the point of plethora and one morning after a large breakfast he fell dead. In this case the venous flood had been rising against the narrowed isthmus at the mitral valve and finally the right heart became acutely over-distended and failed. In such a case a prompt bleeding might have saved the patient but the disaster might have been avoided by a spare dietary and the use of laxatives. The adverse conditions affecting the heart in severe cases of pneumonia were somewhat similar although more complex; a weakened heart, an impaired lung function, and an actual impediment in the lungs from extensive stasis of capillaries were the factors. The oncoming over-distension of the right heart could be noted in its increased dimensions and the loud second sound, coupled with the limited output as recognised in the small quick pulse at the wrist, which failed during each inspiratory period. Venous stagnation was further witnessed in the fulness of the liver and the albuminous urine. Sir Douglas Powell urged the importance of carefully guarding against over-feeding patients in this condition. The chief preventives against heart failure in pneumonia were careful feeding, occasional laxatives, strychnine, and oxygen. With regard to strychnine he had not the slightest doubt, from clinical experience, that it was a direct and powerful heart stimulant, although it was maintained by pharmacologists that it raised blood pressure by its effects in contracting the arterioles, not by its direct effect upon the heart. If this were so it would be of doubtful value in pneumonia, whereas he thought all physicians would agree as to its usefulness The main value of oxygen inhalation was as a cardiac stimulant and it should be administered at stated times. The blood charged with free oxygen passed directly to the heart, refreshed its muscular power, and prevented the accumulation of waste products. Digitalis was chiefly valuable in cases in which the heart rhythm became disordered. Caffein might supplement or replace strychnine in some cases. In cases of heart failure in Addison's disease, in hæmorrhage, and in collapse after abdominal injury or operation the blood pressure became very low and there was a tendency to transfer the blood from the arteries into the veins. To combat this tendency ergot, suprarenal extract, and saline injections were of value according to the cases, the object being to raise arterial tension and to retain more blood in the arteries and the nervous centres. The heart would still require support by strychnine, digitalis being in most cases contraindicated. The merits of rectal, subcutaneous, and intravenous injections were touched upon.

Opium was referred to as a most valuable aid to other remedies in all cases of what might be described as cardiac shock or cardiac pain, in cases of painful as apart from syncopal angina, and in irregular, tumultuous or inhibited action of the heart attendant, for instance, upon the initial shock of extensive pleurisy or acute pericarditis. Again *in that peculiar condition of cardiac agitation attended by* restless dyspnœa and air hunger that often preceded the appearance of dropsy morphia subcutaneously was often the only remedy that afforded relief.

Sir WILLIAM BROADBENT said that he had followed with interest the different causes of cardiac failure alluded to by Sir Douglas Powell Cardiac dilatation might also be secondary to inherent decay of the heart and to diseased con*ditions of the aorta, causes which were perhaps some of the* most common they met with. Genuine cases of angina might arise from disease of the coronary arteries. As regards sudden death in mitral stenosis, it might not only be caused by venous congestion but it might also be due to the mechanical distension of the stomach pressing directly on the right side of the heart as in a case which he mentioned. Bleeding was an admirable remedy in some cases of *pneumonia. Strychnine was a most valuable remedy in* cardiac failure. Five grains of calomel were a prompt and efficacious remedy in many cases.

Sir LAUDER BRUNTON, referring to sudden death in mitral stenosis, thought that it might very often be due to mechanical effects produced by the stomach. This was the explanation of the death of people by making them drink large quantities of bullock's blood in the Middle Ages. Cardiac *distress very often arose from distension of the stomach* by wind or other causes. He believed the heart might actually be tilted upwards upon itself. It was very important to avoid fermentative substances in the diet and to avoid fermentation by the administration of carbolic acid and other remedies. He had seen great advantage in occasional bleeding in pneumonia when the right side of the heart was distended. By pharmacological experiment he had found *that strychnine* was a *direct stimulant of the cardiac* ganglia; thus he concurred with what previous speakers had said. Reference was made to a case of pneumonia in which the continuous administration of oxygen was very successful Rest in bed was, in his belief, the most efficacious of all methods of treatment of cardiac failure.

Dr. JOHN MITCHELL BRUCE, referring to acute failure of the heart in mitral stenosis, advocated venesection, especially when hæmoptysis appeared, which *was nature's indi*cation for this plan, or failing this 12 leeches might be applied along the sternum. In both acute pneumonia and chronic valvular disease the cardiac embarrassment might be due to an overloaded stomach when emesis and calomel were the best remedies. In pneumonia far too much food was generally given. He advocated the continuous rather than the intermittent administration of oxygen in pneumonia and it should be started before urgent symptoms set in. It might be given through a tube opening just under the patient's chin. Digitalis was an invaluable drug in the cardiac failure of chronic valvular disease and in Bright's disease. It should be given in large doses (from ten to 15 minims of the tincture every four hours) and the dose might be increased if moderate doses failed or produced a fluttering pulse The daily amount of urine passed should always be gauged; it was the most certain measure of the efficacy of the drug and of the progress of a case of chronic valvular disease.

Mr. A. E. J. BARKER, speaking of the cardiac failure following operation, said it might be immediate, as in shock, or remote, occurring a day or two after the operation. The remote variety might be due to toxæmia In the cardiac failure of shock the blood pressure was very low and this low pressure could be increased by handling the abdominal organs roughly. The infusion of normal saline solution was useful Glucose (up to 5 per cent) might be added. Adrenalin might be given subcutaneously.

Mr. A. W. MAYO ROBSON thought a great deal could be done to prevent shock and cardiac failure by measures adopted prior to operation—namely, by preserving the warmth of the patient, by injecting a pint of normal saline solution into the bowel, and by the hypodermic injection of ten minims of strychnine solution. *He had used these measures* several hundred times with success. For the cardiac failure after operation he advocated oxygen and the use of saline injections intravenously and per rectum. Three or four pints might be given during and after an operation. He was satisfied that in certain cases acute distension of the stomach might cause all the symptoms of acute cardiac failure.

Sir DOUGLAS POWELL replied.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

The Relation of Mental Symptoms to Bodily Disease.—The Mental and Moral Effects of the South African War, 1899–1902, on the British People.—Fragilitas Ossium in the Insane

A GENERAL meeting of this association was held at the *rooms of the Medical Society of London, 11, Chandos street,* Cavendish-square, W., on Nov. 18th, Dr. ERNEST W. WHITE, the President, being in the chair.

Dr. NATHAN RAW read a paper entitled "The Relation of Mental Symptoms to Bodily Disease, with special reference to the Treatment of Temporary Forms of Insanity outside Lunatic Asylums." He said that his object was to direct attention to the great frequency with which mental symptoms *were developed in an attack of bodily illness and to the un*satisfactory system obtaining in this country of treating and dealing with persons suffering from temporary mental disease. It was not his purpose to speak of active organic insanity for which the asylum was the proper place, but of those persons who in the course of such diseases as pneumonia, typhoid fever, Bright's disease, toxic poisoning (as by belladonna), puerperal septicæmia, exophthalmic *goitre, gout, and myxœdema required special pro*vision in the shape of nursing and treatment without having recourse to certification and without placing them among those who could be correctly described as of unsound mind. His position could be summed up by such a case as the following. A man without means became temporarily insane during an illness and attempted suicide. His friends could not afford to pay for his treatment, therefore *he was taken to the insane wards of a workhouse infirmary.* The symptoms passed away but the law said that no person should be detained in the insane wards of a workhouse for more than for 14 days; hence the man would be duly certified by a magistrate as insane and removed to an asylum, which was a hardship. He would like to see established in every town, preferably by the municipality, a reception hospital for mental diseases, from which, if recovery did not *ensue in six weeks, cases should be drafted to the asylums* proper. He could say from his own experience that many people were now sent to asylums who, if they had been accommodated in such reception houses, would have recovered and—which was very important and not a matter of sentiment—would have been spared the stigma of lunacy, a stigma which in many cases prevented a man subsequently obtaining employment. He admitted that by such a pro*vision the "recovery-rate" of* asylums would be much diminished but in the face of the great benefit to the community he could not imagine any alienist offering objection on that account. The position was somewhat acute in Lancashire where, although there were five county asylums averaging over 2000 patients, it was almost impossible to find accommodation for all the lunatics and practically all the admissions into the asylums were made from the workhouses. During the last six years under Section 20 of the Lunacy Act there had been admitted into Mill road Infirmary, Liverpool, 3934 lunatics. Of that number 1003 were suffering from delirium tremens and other results of alcohol, so that 2931 suffered from other causes of insanity. Of the 3934 1982 were transferred to the county asylums and 1605 recovered within the scheduled time allowed by law, while the remaining 347 died. In Glasgow the reception-house method had worked satisfactorily for some months and the London County Council was *empowered to provide four* reception houses on the same lines. Dr. Raw then proceeded to amplify his contention by relating instances of the several diseases associated with temporary mental aberration, paying
special attention
He objected to th
and invited an
association —Dr. G. H. SAVAGE said that the paper should *be considered from two aspects—first, the practical one as* to patients being first received in reception houses, and, secondly, the forms of mental disorder which should be sent to them. He was in accord with the desire that patients suffering from temporary mental disease should not be treated as, or termed, insane cases and if the dictionary could be

purged of such terms as "lunatic" and "asylum" much good would result. The homes, asylums, or hospitals for the insane were admirably managed and if patients could be sent to them without the formality of certification, and not only sent but detained, it would be a most desirable thing. The real difficulty was that a patient was willing to go as a voluntary boarder but was not willing to stay there, and if he were subsequently certified it was thought that a mean advantage had been taken of him. But if he came out harm followed to all. Perhaps some of the asylums could be utilised as reception houses but all would probably agree that some expansion of the law was required and he thought that the liberty of the medical man should be considerably increased.—Dr. A. R. Urquhart said that Dr. Raw's early asylum experience, followed by a remarkably large clinical one, eminently fitted him to bring forward such a subject. The question of receiving houses for the insane was a very old one and unnecessary difficulties had been made with regard to it. It was 30 years ago that he saw the receiving house of the late Dr. Norton Manning at Sydney and in that remote colony at that date was a similar institution to those now being striven for in England, and it was under the care of the physician responsible for the treatment of the insane in the neighbouring asylums of the colony. He deprecated the idea that a general physician was competent to take charge of such receiving houses.—Dr. J. Wiglesworth said he had hoped that Dr. Raw would have given his views on the pathology of some of the conditions which he had described. He did not think that there were so many cases of bodily disease associated with insanity as Dr. Raw made out. The most suitable cases for reception houses were acute alcoholics but he did not agree that they should not be regarded as insane; they were as insane as subjects of any other form of paranoia. He urged that the town was quite the wrong place in which to treat such cases. The more restful and delightful surroundings of the country were a great help to recovery. The period of detention of cases sent to receiving houses he thought should be nearer a fortnight than six weeks.—Dr. Robert Jones pointed out that the period set by the London County Council was six weeks but it could be extended more or less indefinitely by further periods of six weeks. He thought that Dr. Raw had fully established the necessity for such reception houses and he entirely supported Dr. Wiglesworth's contention that such houses should at any rate be suburban. He did not think that an asylum was the proper place to send alcoholics to.—Dr. W. Lloyd Andriezen would have liked to hear the conditions mentioned by Dr. Raw classified and he (Dr. Andriezen) outlined the scheme on which he thought such classification should be based. He also protested against the old metaphysical division of ailments of the mind from those of the body and emphasised the frequent presence of a hereditary neurosis in cases where bodily disease caused mental symptoms.—Dr. W. Crochley S. Clapham and Dr. F. R. P. Taylor continued the discussion, the latter referring to the reception hospital attached to the East Sussex County Asylum which he thought was as near that which Dr. Raw advocated as anything could well be.—Dr. Bower also referred to the same institution and to the large part taken in its establishment by Mr. H. F. Hayes Newington.—The President approved of the suggestion to establish reception houses for temporary cases but urged that every care should be taken that the presiding genius of such institutions would be a properly trained psychologist.

Dr. R. S. Stewart read a paper entitled "The Mental and Moral Effects of the South African War, 1899–1902, on the British People," in which he showed by summaries of criminal statistics that the nation as a whole was much more self-possessed during the dark days of the war—the end of 1899—while since then a reaction had been apparent. – The paper was discussed by the President, Dr. Jones, Mr. Hayes Newington, and Dr. Andriezen.

Dr. W. Maule Smith showed a most interesting series of slides illustrating the existence of Fragilitas Ossium in the Insane, often of a very extreme degree.

The members afterwards dined at the Café Monico.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Case and Specimen.—Paralysis of the Third Nerve.—Pneumonia.

A MEETING of this society was held on Nov. 19th, Mr. Rushton Parker, the President, being in the chair.

Dr. W. Alexander showed a patient from whom he had removed the Breast some time before. On admission operative interference was apparently hopeless as the tumour was adherent to the subjacent structures, ulcerating, and very foul. After the free application of creolin to the growth and the administration of thyroid tablets the tumour lost its hold on the deep tissues and was removed by two operations. The microscope showed the growth to be adeno-carcinoma. The question arose whether the thyroid tablets or some toxin from the septic condition was the factor in the change. —Mr. F. T. Paul and the President thought that the improvement was brought about by toxic products derived from the septic infection.—Dr. A. S. F. Grünbaum also spoke.

Dr. Alexander also showed a Double Uterus, each part being only adherent at the cervix. Each uterus had a distinct os and canal, one Fallopian tube, and one ovary; the formation of the organs was evidently due to absence of coalescence of Müller's ducts. The organ was removed for adeno-carcinoma of the cervix; the posterior uterus was thought to be a fibroid. The patient was a 3-para. During the first two pregnancies she had amenorrhœa and in the third she menstruated till within two days of the birth of the child.—Dr. H. Briggs spoke and Dr. Alexander replied.

Mr. R. J. Hamilton read a short paper on Paralysis of the (left) Third Nerve with Blindness on the same side due to a retrobulbar neuritis. After a discussion of the possible etiology Mr. Hamilton held it to be due to periostitis of the sphenoid, probably rheumatic in nature. The patient, a girl, aged 20 years, was shown.—Mr. Richard Williams had seen two or three similar cases in which he had diagnosed periostitis at the entrance into the orbit. The symptoms had subsided under the use of mercury and iodide of potassium alternately. The prognosis depended upon the rapidity with which the patient was brought under the influence of mercury.—Dr. K. A. Grossmann thought that the etiology was generally obscure unless traumatic. Prognosis was even more uncertain; the patient, whom he had exhibited on March 19th of this year, though mercury and iodide had been freely given, still showed paralysis when seen a fortnight ago.—Mr. Hamilton, in reply, said that his patient was improving under iodide and salicylate.

Dr. John Hay read a paper on Pneumonia. It was based on the observation and notes of 150 cases. Of these 150 cases 21 were admitted moribund or died within 24 hours of admission. After eliminating these there was a death-rate of 31 per cent. Alcoholic excess was much in evidence. It was admitted in 65 of the 150 cases and of these 65 37 died. After discussing certain physical signs and some points in the physical examination he dealt with the question of cardiac strain and the effect of the onset of hepatisation, the toxæmia, the temperature, delirium, and struggling on the heart, and he emphasised the far greater importance of the condition of the myocardium in the prognosis than the existence of valvular disease and brought forward numerous cases in support of this view. The signs of cardiac failure were then discussed, especial emphasis being laid on the importance of careful definition of the deep cardiac dulness. He pointed out the extreme gravity of the prognosis in cases where an irregularity of the pulse was present before the crisis excepting in the aged or in those cases where there was marked mitral stenosis. The causes and treatment of sleeplessness, delirium with struggling, and flatulent distension of the abdomen were discussed and the indications and contra-indications for the administration of morphia. Dr. Hay was of opinion that the value of alcohol in the treatment of pneumonia was much overrated owing to a misconception of its therapeutic action. It was of use in order to counteract any contraction of the peripheral vessels such as occurred during the initial rigor or as a narcotic, and also during convalescence, but he held that the consensus of scientific opinion was opposed to the view that in its specific action it was a cardiac stimulant. He gave the results of 47 cases which were treated throughout without alcohol as compared with 103 which received it when the orthodox indications for its use arose. The patients in each class were so far as possible of a similar type and yet after eliminating those admitted dying from both classes the mortality in class 1 was 21½ per cent. as compared with 36½ per cent. in class 2; the average age in each class was about 33 years. The action and value of digitalis strychnine, caffeine, and ammonium carbonate were discussed and the treatment by the application of ice-bags to the abdomen was referred to.—Dr. Nathan Raw would lay great stress upon the severity of the infection when considering the death-rate under any particular form of treatment. At times the severity was such that practically no treatment was successful; at other times the majority would recover. In an intermediate class much could be done and his practice had been not to spare the use of alcohol when the symptoms appeared to demand it. They must look forward to the discovery of a direct antidote to the pneumonic poison.—Dr. W. CARTER said that there were only two periods in any case of acute pneumonia when he would like to use opium—viz, at the onset and certainly never later than the second or third day if the nervous centres were markedly affected, and at the very end of the disease when the critical fall of temperature was followed by active delirium. In the latter case, though the physical signs were not much altered, the vital relations of the patient were such that a timely dose of opium was of the utmost value.—Mr. ALBERT E. DAVIS said that his routine practice was to give ammonium carbonate and six ounces of brandy per diem. His death-rate was under 10 per cent. in the last 18 years. He deprecated the use of opium in any form at any period of the disease.—Dr. W. B. WARRINGTON, Dr. T. R. BRADSHAW, Dr. T. R. GLYNN, Dr. C. A. HILL, Dr. J. BARR, Dr. GRÜNBAUM, Dr. C. J. MACALISTER, and Dr. J. H. ABRAM also spoke and Dr. HAY replied.

EDINBURGH OBSTETRICAL SOCIETY.

Election of Officers.—Valedictory Address.—Leucocytosis in Pelvic Disease.

A MEETING of this society was held on Nov. 11th, Dr. JAMES RITCHIE, the retiring President, and afterwards Professor A. R. SIMPSON, Vice-President, occupying the chair.

The following members were elected office-bearers for the ensuing session:—President: Dr. N. T. Brewis. Vice-Presidents: Professor A. R. Simpson and Professor J. A. C. Kynoch (Dundee). Treasurer: Dr. William Craig. Secretaries: Dr. William Fordyce and Dr. J. Lamond Lackie. Librarian: Dr. F. W. N. Haultain. Editor of Transactions: Dr. Lamond Lackie. Members of Council: Sir J. Halliday Croom, Dr. Michael Dewar, Dr. G. Matheson Cullen, Dr. J. E. Moorhouse (Stirling), Dr. James Ritchie, Dr. J. W. Ballantyne, Professor R. Jardine (Glasgow), and Dr. W. G. Aitchison Robertson.

The PRESIDENT in his Valedictory Address mentioned that during the last two years the membership had been increased by the addition of 22 Fellows, making 449 ordinary Fellows on the roll, and with honorary and corresponding Fellows a total of 567. He referred to the loss the society had sustained in the death of several of the Fellows and gave a short sketch of some of their lives. The work of the past session was also reviewed and summarised.

Dr. G. SCOTT CARMICHAEL read a paper on Leucocytosis in Pelvic Disease giving the results of examination of the blood made in 180 gynæcological cases and in many cases of pregnancy while studying in Greifswald under Professor Martin. For a complete investigation not only the quantitative change in the leucocytes alone must be taken into account but also the qualitative changes as evidenced by the proportion of the polymorphonuclear leucocytes to other forms or by such a change as is presented by their iodine reaction. For clinical purposes, however, the quantitative change in the leucocytes was sufficient. It could be rapidly ascertained and with few exceptions could be relied upon to betray the chief changes in the blood. The importance of the use of this examination in all cases of inflammation of the pelvic connective tissue could not be over-estimated. To obtain a proper standard it must be remembered that towards the end of pregnancy and during parturition the leucocytes tended to increase steadily, while during the puerperium there was as steady a decrease in all cases unattended by complications or operative interference. Up to 15 000 per cubic millimetre was considered within the range of a normal pregnancy by Zangemeister and Wagner. Dr. Carmichael had not observed any count in his cases to rise above 13,000, the average being 10,000 or 11,000 The leucocyte count was very helpful in deciding the question of the presence of pus in chronic inflammatory pelvic cases with no rise of temperature though the leucocytosis was not so high in these cases as in the acute ones. They must attach great importance to a slight rise in the leucocytes in a chronic case, especially if it was steady and gradual. The presence or absence of pus in tubal affections and also the source of the suppuration could be largely determined by a leucocyte count. Pyosalpinx caused by streptococci might produce a leucocytosis up to 40,000 per cubic millimetre, and the bacillus coli communis also caused a high degree of leucocytosis. Gonorrhœal inflammation caused a moderate degree, at highest up to 15,000; a tuberculous inflammation was lowest on the scale, causing no leucocytosis. In three cases of ectopic gestation there was no increase of the leucocytes, the numbers being respectively 6100, 8200, and 7100. So that this estimation could differentiate the source of the inflammation present. Some considered that malignant tumours produced an increase in the number of leucocytes; inflammatory complications of tumours would do so. In appendicitis a count of 25,000 or over would probably mean suppuration, but a surgeon would fail in his duty if he waited till this number were reached as other signs were of importance. At the commencement of an acute inflammation there might be considerable increase of leucocytes and yet no suppuration; but if after daily consecutive examination the count remained about or above 20,000, or if there was a steady rise towards that number, then the presence of pus might be suspected. In cancer of the cervix with much ulceration there was often considerable leucocytosis and no operation would be advisable until this increase was much diminished by appropriate treatment. After a severe hæmorrhage as in cases of uterine fibroids, there was often considerable leucocytosis.—Professor SIMPSON, Dr. G. L. GULLAND, Dr. D. BERRY HART, and Dr. BALLANTYNE discussed the paper.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 6th, Dr. Seymour Taylor, the President, being in the chair.—Dr. Herbert Tilley showed a case of Chronic Suppuration of the Accessory Nasal Sinuses cured by operation. The patient, an unmarried woman, 41 years of age, had suffered from profuse purulent nasal discharge for about ten years, the condition following upon an attack of enteric fever. For about five years headache had often been so severe as to preclude the performance of her duties, while mental apathy and inability to concentrate her mind upon her work had been a more or less constant symptom. During this time polypi had on several occasions been removed from the nasal cavities without producing any effect on the discharge from the nose. On Jan. 12th of this year Dr. Tilley operated on both frontal sinuses by completely removing the anterior wall, curetting away the polypoid pyogenic membrane, and making a large opening into the nose by way of the fronto-nasal canal The ethmoidal and sphenoidal cavities were also dealt with at the same time by curettage. On Jan 28 h the maxillary antra were opened through the canine fossa, the diseased contents were curetted away, and the sinus cavity was mopped out with chloride of zinc solution (40 grains to one ounce) and lightly packed with bicyanide gauze. At the end of 24 hours the gauze was removed and not reinserted, the antral cavities being irrigated with warm boric lotion, dried, and left alone. No opening was made from the antra into the nose. The healing process was carefully watched and just before the openings in the canine fossæ closed it could be demonstrated that the antral cavity was practically full of organising granulation tissue. The patient had now been free from any discharge for over seven months, her general health was better than it had been for years, and she had increased 17 pounds in weight. There was practically no scarring over the frontal sinus regions.—The President considered that the chief interest in the case, apart from the extensive and general suppuration of the accessory sinuses, lay in its association with enteric fever and referred to the extremely varied nature of the complications and sequelæ of that disease —Replying to a question by Mr. G. A. Garry Simpson, Dr. Tilley stated that he did not consider that the suppuration had been started by the typhoid bacillus. Probably the antra were suppurating before the onset of the enteric fever and the low state of health induced by that disease brought about a rapid infection of the other accessory nasal sinuses —Dr. Tilley also showed a case illustrating an operative procedure for the relief of almost complete adhesion between the soft palate and the posterior pharyngeal wall, the result of tertiary syphilis. The adhesion was so complete that only a small probe could be passed from the oro pharynx to the naso-pharynx. The patient, a girl 23 years of age, had been operated on twice previously but re-adhesion had occurred on each occasion. After a preliminary laryngotomy Dr. Tilley completely divided the adhesions between the palate and the pharynx. A strong silver wire was then passed from before backwards through the soft palate close to its junction with the hard palate about half an inch from the middle line. The distal end of the wire was then made to re-pierce the soft palate close to its free margin and from behind forwards, so that a short segment of the wire rested on the posterior surface of the soft palate. The free ends of the wire were then passed from behind forwards one upon each side of the root of an incisor tooth, firm traction was exerted on the palate, and the wires were twisted upon one another and cut off short in front of the tooth. A similar procedure was adopted on the other side of the palate. The wires cut out in about a fortnight and by that time the raw surfaces (corresponding to the previously adherent areas) had become practically covered with epithelium and hence no re-adhesion took place.—Replying to Mr. W. McAdam Eccles, Dr. Tilley stated that he had closed the laryngotomy wound at once. A certain amount of subcutaneous emphysema followed, affecting the right side of the face and the neck, but this disappeared in about a week.—Mr. McAdam Eccles showed a case of Sarcoma of the Os Pubis occurring in a girl, 11 years of age. Four months previously pain in the right leg, chiefly in front of the knee, had been complained of. At that time there was no abdominal swelling. When the swelling appeared operation was advised but declined and the tumour had rapidly increased in size. The patient was fairly well nourished and could stand and walk without discomfort. In the hypogastric region there was a large globular swelling, hard, fixed, and somewhat overlapping the body of the os pubis. Part of the tumour to the left side was softened. The inguinal glands were enlarged. Rectal examination showed that the uterus was displaced backwards and projected against the anterior wall of the rectum. There had been no interference with micturition or defecation and the temperature had remained normal. The tumour was of such a size that operative procedure seemed to be out of the question and Mr. McAdam Eccles was unable to advise treatment by Coley's fluid or serum injection.—Dr. E. Furniss Potter showed a case of Radical Mastoid Operation in which rapid healing took place without skin grafting. The patient was a girl, aged 14 years. Operation was rendered urgent by the supervention of an acute attack of chronic middle-ear disease. The operation was performed with great ease, the outer bony wall of the antrum being much softened. The patient did well until the eighth day when a severe attack of erysipelas lasting for 18 days occurred. Thereafter the patient made a good recovery and two months after the operation healing was complete. Dr. Potter considered this to be an unusually good result and quoted Mr. C. A. Ballance's statement[1] that the average time necessary for complete healing in cases similarly treated is from six to seven months.—Dr. E A. Saunders showed a case of Rickets with Anæmia and great Enlargement of the Spleen. The patient, a boy aged nine years, had been admitted to hospital five weeks previously complaining of abdominal pain and shortness of breath. The most striking features of the case at that time were an intense anæmia together with very great enlargement of the spleen and, to a less degree, of the liver. The head was large and square with marked bossing of the temporal and parietal regions. There had been no recent illness and the family history showed nothing of importance. On examination of the blood the anæmia was found to be of a simple type, the red corpuscles being 1,780,000 and the white 5000 per cubic millimetre. The hæmoglobin was about 40 per cent. The spleen reached to the middle line well below the umbilicus and the liver could be felt two and a half inches below the costal margin. There were no lymphatic enlargement, no purpura, no hæmorrhages, no œdema, and no rise of temperature. Under a tonic treatment, consisting of arsenic, iron, and cod-liver oil, together with good food the improvement was extremely rapid. The red blood corpuscles had increased to 3,880,000 and the white to 8000 per cubic millimetre and the hæmoglobin had risen to 75 per cent. The anæmia had practically disappeared and both the liver and the spleen had decreased in size.—Mr. L. S. Dudgeon urged the importance of a complete examination of the blood with a differential count of the leucocytes in such cases and referred to the fact that the enlargement of the liver and the spleen might be more apparent than real.—Mr. C. R. B. Keetley showed (1) a case of extensive Contracture after severe Burns; and (2) a case of Carotid Aneurysm in a woman.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on Nov. 20th, Dr. B. A. Whitelegge, the President, being in the chair.—Dr. W. J. Simpson read a paper on the Epidemiology of Plague. After referring to the many unsolved problems as to its etiology and migrations in the past he pointed out that the present epidemic sprang from a centre remote from those of previous outbreaks and that its distribution had been equally dissimilar from theirs It had everywhere followed maritime trade routes, not passing inland in China save by the great water-ways. Its retrogression from western Europe about the close of the seventeenth century and from its eastern confines 100 years later was due, not to any social changes or sanitary progress, but to the transference of the trade of the East from overland to maritime routes. From the tenth to the sixteenth centuries the products of China and India were carried by caravans through Persia and Syria. The commerce of Europe was wholly in the hands of the Venetians and Genoese, by whom the goods were distributed to the ports of the Mediterranean, and of the German merchants of the Hanseatic League who transported them overland from Venice to central and northern Europe, affording the amplest opportunities for collecting the infection in its home and spreading it throughout the continent. But after the Portuguese discovered the sea route to India and the Far East the Dutch and later the English built up a world commerce over the high seas, and the substitution of the Red Sea route for that *viâ* the Euphrates Valley and the Caspian Sea closed the last of the direct routes between plague lands and Europe. But it was a matter for serious consideration whether the construction of railways in Asia Minor, Syria, and Persia would not be opening up the old trade routes through countries where the plague was endemic with the substitution of more rapid means of locomotion, for it was not certain that the sea even with its many advantages would always retain its supremacy as a means of international trade. At the present time Hong-Kong, the centre of distribution of the commerce of the Far East, Australia, and the western States of America, was a plague centre also The seasonal incidence of epidemic outbreaks was governed by some law, for though cases would occur at all or at any times it appeared as an epidemic in certain seasons marked in each zone and climate by approximation to a type. In Europe it was in late summer and autumn, in Egypt somewhat earlier; south of the equator, as at Cape Town and Sydney, from March to May, corresponding to the September to November of northern and central Europe; while in India there were spring and autumn waves depending on the climate. The rise, duration, and decline of each outbreak followed a certain type, little influenced by natural conditions or human efforts save that mean temperatures below 50° F. or above 83° were inimical, but it was not easy to understand how the latter could affect a bacillus the natural habitat of which was the blood at a temperature of 100° unless it were under extra-corporeal conditions. The susceptibility of the domestic animals was a matter of importance. Notwithstanding the failures of Haffkine and others Dr. W. J. Simpson, Dr Hunter, and Dr. Matsuda had succeeded in infecting swine and poultry, as well as monkeys, ruminants, and other animals.—Dr. F. M. Sandwith stated that of 200 ferrets imported into Cape Town very few survived, for though they did kill the rats they were themselves even more susceptible to the plague The alleged inexplicable disappearance of the plague from Egypt in 1844 and until recently was simply due to the official suppression of reported cases —Dr. R A. Farrar, Sir Patrick Manson, the President, Dr L W. Sambon, Mr. B G. Corney (Fiji), and others also took part in the discussion.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held at the Medical Institute, Birmingham, on Nov 18th, Mr. Arthur Oakes being in the chair.—Dr. C. E Purslow showed a Broad Ligament Cyst removed by abdominal section. The patient, aged 72 years, the mother of 11 children, was admitted into hospital with a cystic tumour of the abdomen of the size of a full term pregnancy. She first noticed that her abdomen was enlarging four months previously. Shortly before this she had received a very severe

---

[1] THE LANCET, April 11th, 1903, p. 1010.

blow on the abdomen On opening the abdomen the cyst was tapped and then after its peritoneal covering had been incised enucleation was commenced The tumour invaded both broad ligaments completely so that it was impossible to say from which side it sprang originally The patient made an uninterrupted recovery Dr Purslow drew attention to the superiority of vaginal drainage to drainage through the abdominal incision —Dr Purslow also showed a Mucous Polypus of an unusual size removed from the cervix uteri — Dr. J G Emanuel showed a case of so called Crossed or Alternating Paralysis The patient was a young married woman, 25 years of age, who presented a complete motor paralysis of the face arm, and leg on the right side of the ordinary hemiplegic type, without wasting and with increased tendon jerks, ankle clonus and the Babinski reflex. There was no disturbance of sensation or coördination of the muscular or stereognostic senses The patient also exhibited paralysis of the left fifth cranial nerve, relative anæsthesia of the anterior part of the scalp, the face, the conjunctiva, the mucosa of the mouth, the lips, the tongue, the hard and soft palate, and the nose on the left side, together with hyperalgeeia over this area, there was also loss of power with wasting of the temporal, masseter, external pterygoid, and tensor palati muscles of the left side The senses of smell and taste were unimpaired The root of the left sixth cranial nerve was completely paralysed and there was paralysis of the left side of the tongue (hypoglossal nerve) All the ocular muscles, both intrinsic and extrinsic, acted well with the exception of the paralysed left external rectus There was no weakness of the left facial nerve or of the left arm and leg, but the tendon reflexes (triceps, wrist, patellar, and tendo Achillis) were exaggerated on the left side, ankle clonus and Babinski's reflex, however, were absent In addition to these localising symptoms there were certain well ma
as severe headaches cerebral
ic neuritis was absent. Dysphc
symptom and dysarthria was conspicuous and accompanied by a constant dribbling of saliva from the left angle of the mouth There was no paralysis of the larynx, neither was there incontinence of urine or fæces, albuminuria or glycosuria. The patient's general nutrition was good and her intellect was clear and keen These symptoms had come on insidiously and had gradually become more and more marked during a period of from six to seven months in spite of a long continued course of mercury and iodide of potassium in large doses Dr Emanuel thought that the symptoms were probably due to a tumour in the pons growing from the basisphenoid and the basioccipital region —Dr J D Stanley favoured the view of a gliomatous infiltration of the pons —Dr Wilfrid Glegg read a paper on Chronic Inflammation and Suppuration in the Ethmoid He described empyemata of the ethmoidal labyrinth in their latent, evident, open, and closed forms and discussed methods of diagnosis and differentiation of ethmoidal empyemata from purulent collections in other accessory cavities of the nose

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION —The annual general meeting of this society was held on Nov 13th, Dr V H Wyatt Wingrave the President, being in the chair —The following officers were elected for the ensuing year —President Mr John Bark (Liverpool) Vice Presidents Dr R H Woods (Dublin), Dr William Lamb (Birmingham) Mr St George O Reid and Dr Atwood Thorne Council (metropolitan) Dr Wyatt Wingrave (*ex officio*) Dr C O Hawthorne Mr W J Chichele Nourse, Dr. P H Abercrombie and Dr W Jobson Horne, (extra me
and Mr Samuel I
Percy S Jakins
Mr W Stuart Lc
Persistent Superficial Nasal Hyperæmia cured by removal of adenoids, in a male, aged 25 years —Mr Mayo Collier, speaking of this case, referred to several similar cases of his own where improvement had followed turbinal cautery —Dr J Dundas Grant spoke of a similar case where he had scarified the vessels and applied pure carbolic acid with excellent results. He thought that the vestibular portions of the nasal fossæ ought to be more carefully examined in these cases as follicular abscess was a cause of red nose —Dr Frederick Spicer showed a case of Accessory Tragus (bilateral) —Dr Dundas Grant showed a case of Fibroma of the Naso pharynx in a boy The operation for the removal of the growth was attended by remarkably little bleeding and was highly successful —Mr Mayo Collier showed a case of Frontal Sinus Disease in which recurrence of suppuration had followed the external operation and was only cured after removal of the greater part of the middle turbinal —Dr Dundas Grant strongly insisted on the principle that in these cases the anterior part, at least of the middle turbinal should be removed first of all before resorting to the external operation and that in many cases the performance of this partial turbinotomy would obviate the necessity for the much more severe external operation —Mr Bark instanced cases where in his opinion, a nasal operation had prevented the necessity for the radical operation for frontal sinus disease —Other cases and specimens were shown by Dr W H Kelson and Dr Jobson Horne —Dr W D Haslam described an Improved Screw Maxillary Antrum Perforator —Dr Perry Goldsmith (Canada) communicated notes of an unusual case of Empyema of the Maxillary Antrum — Mr Chichele Nourse showed a specimen of Radium

EDINBURGH ROYAL MEDICAL SOCIETY —A meeting of this society was held on Nov 20th, Dr D C L Fitzwilliams being in the chair —Dr C B Hamilton gave from the chair his presidential address, his subject being "The Hospital" After sketching shortly the evolution of the institution, he devoted himself mainly to the present abuse of hospitals maintained by charity Those he specially emphasised were (1) the use of the hospital by people who could afford to pay for medical advice, (2) the tendency among the poorer subscribers to think that their subscription entitled them to all the benefits of the institution, (3) the practice among outside medical men of sending troublesome cases into hospitals, and (4) the habit among hospital physicians of *keeping interesting cases under observation in the wards for* inordinate periods of time As remedies for some of these evils the President suggested that general hospitals might be maintained as fever hospitals and lunatic asylums are by taxation and that more homes should be provided where middle class patients could be treated at reasonable charges —Dr W E Carnegie Dickson read notes on a case of Hyperpyrexia The patient was a woman who had had previous attacks of chorea—one of them during pregnancy During labour with a subsequent child she developed nervous symptoms with choreic movement and acute pains in the limbs Hyperpyrexia to the extent of 108° F occurred a few days after parturition and in spite of energetic treatment, which was successful in reducing the temperature, the patient succumbed —A dissertation on Constipation by Dr W H Prentice was read in his absence by Dr B P Watson

NORTH LONDON MEDICO-CHIRURGICAL SOCIETY — A clinical meeting of this society was held on Nov 12th, Mr Peyton T B Beale the President, being in the chair — Dr S E Dore showed a case of Lupus which had been successfully treated by the Finsen light in one part and by the x rays in another part The former had given the better result Various other modes of treatment had been adopted in this case without any good results. A photograph of the patient before treatment was exhibited.—Dr. T. J. Horder showed two cases of Paralysis Agitans accompanied by Osteo arthritis and a case of Tabes Dorsalis accompanied by Spondylitis Deformans.—Dr. A. Morison showed a case of Graves's Disease of recent date in a young man The wasting was very marked. There was no family history of this or of any allied diseases.—Dr. H. W. Syers showed a patient suffering from Spastic Paraplegia, the right leg being much more spastic than the left. The diagnosis was discussed.—Mr G. B. Mower White showed a case of Subspinous Dislocation of the Humerus in a girl, with a skiagram. There was some doubt as to whether the case was congenital or whether the condition followed infantile paralysis —Mr. White also showed a young woman from whose Knee joint a damaged Internal Semilunar Fibroid Cartilage had been removed.—Mr. Upcott Gill, Mr. A. Hair, and Mr. A. de Morgan showed pathological specimens.

Reviews and Notices of Books.

A Short Practice of Midwifery, embodying the Treatment adopted in the Rotunda Hospital, Dublin. By HENRY JELLETT, B A., M D., B Ch. Dub. Fourth edition, revised. With 152 Illustrations and an appendix containing the statistics of the hospital for the last 13 years. London : J. and A. Churchill. 1903. Demy 8vo. Pp. 557. Price 8*s.* 6*d.*

ONLY two years have elapsed since the appearance of the last edition of this text-book. The rapidity with which the various editions have been called for shows that it has met with much appreciation amongst students. The author has carefully revised the present edition but unfortunately has been compelled to increase its size. It is to be hoped that in the future he will be able to limit this tendency and to keep the book within its present convenient compass. In our notice of the last edition we called attention to a mistake in the table on p. 16. We see that it has been altered but the table still gives a very inaccurate account of the heights of the uterus, at any rate at the fourth and fifth months of pregnancy. We again would commend to Dr Jellett a study of the frozen sections of Bayer, Waldeyer, and Webster, as well as the writings of Pinard upon this point. On p. 220 we find the statement given on the authority of Winckel that on the ninth day after delivery the fundus of the uterus lies just above the upper margin of the symphysis pubis. We do not know to which of the writings of Winckel the author is referring. In the second edition of his "Lehrbuch der Geburtshülfe," on p. 186, we find that he says, "der fundus uteri am neunten tag des wochenbettes schon hinter der symphyse liegt," which can hardly be translated above the upper margin of the symphysis pubis. Dr. Jellett may quite well be referring to some other statement made by Winckel. We would point out, however, as Webster has shown, that Winckel's description of the rate of involution of the uterus, in the light of the frozen sections published by Webster himself and by others, cannot be accepted as entirely accurate. It is very interesting to note how the uterus might with some accuracy be described, as can be seen in the section published by Webster of the pelvis of a woman on the sixth day of the puerperium, as lying behind the symphysis pubis although the highest point of the organ is, of course, some distance above that level.

These criticisms of minor points in no way diminish our appreciation of the book as a whole. It is, as we have said before, a most excellent work and we can very strongly indeed recommend it to students. Several new illustrations have been inserted in this edition which still further increase the value of the book. The statistics of the Rotunda Hospital for the years 1901 and 1902 have been added to the appendix making up a total of 18,401 cases of labour.

Handbook of Diseases of the Ear, for the Use of Students and Practitioners. By RICHARD LAKE, F.R.C.S. Eng., Surgeon to the Royal Ear Hospital, Lecturer on Practical Otology, Medical Graduates' College With Three Coloured Plates London : Baillière, Tindall, and Cox. 1903 Pp. 232. Price 6*s.* net.

THERE is perhaps no department of medical study which is less known to the average student than otology and this lack of knowledge persists even after graduation in only too many cases. The removal of inspissated cerumen from the ear is often the only treatment ever adopted for this part of the body. For such a condition of things there are at least two main causes. It results partly from the fact that special departments in this subject are of somewhat recent foundation and partly from the fact that it is very rare for any question on otology to be asked at any examination, so that the student prefers to devote his attention to studies more remunerative from an examinational point of view. There is yet another reason for the prevailing lack of knowledge about diseases of the ear and that is the scarcity of text-books on this subject, and therefore we can extend a hearty welcome to the little work lying before us. In the first place, the book is not too big and this is distinctly a merit, for few students or practitioners have much desire or time for a lengthy treatise, and yet the book contains enough of the subject to supply the amount of information required for ordinary purposes. The introductory chapter on the anatomy of the ear is good and is illustrated by sections and diagrams ; it is not too elaborate and says nothing about the structure of the internal ear, but it devotes much attention to the middle ear and the mastoid cells. Other chapters deal with the examination of the patient and special symptoms and their import. A very good section is that devoted to the use of instruments. The most important lesions connected with the ear are those in which there is suppuration in the cavity of the tympanum and its neighbourhood, and Mr. Lake gives a very satisfactory account of middle-ear disease and its complications and an adequate description is given of the operations. The influence of diseases of the middle ear on life assurance is considered and a useful formulary concludes the volume. In the list of counter-irritants we find mentioned linimentum iodi and pigmentum iodi; the former has changed its name in the present Pharmacopœia and the latter has never had an official existence and its composition is liable to vary. We think well of this little volume and consider that it should have a wide field of usefulness.

LIBRARY TABLE.

The After-Treatment of Operations: A Manual for Practitioners and House Surgeons. By P. LOCKHART MUMMERY, F.R.C S. Eng , B.A , M.B., B.C. Cantab., Demonstrator of Operative Surgery, St. George's Hospital ; late Senior House Surgeon, St. George's Hospital. London: Baillière, Tindall, and Cox. 1903. Pp. 221. Price 5*s.* net.—The importance of the after-treatment of patients who have been submitted to operation has hardly been appreciated at its full value. The difference between the results obtained by various surgeons is to be attributed not so much to a difference in their operative skill but in great part to a difference in the care bestowed on the patient after the operation. All surgeons who have had much experience of operations will agree that in spite of a brilliantly performed operation a patient's life may be lost by lack of attention to some small but vital detail in the after-treatment. Important, then, as this subject is it is strange that so little attention has been accorded to it in surgical literature. Scattered about in the various treatises on surgery may be found brief references to special points but we believe that hitherto no attempt has been made to deal in one volume with the whole subject of the after-treatment of operations. Mr. Mummery has done the work well and his book should prove of great value to students and to those who have to look after patients subsequently to operations. Shock is probably at the present time the greatest danger after operation, for thanks to modern methods the risks of sepsis are but small. Mr Mummery prefers to consider shock and collapse as synonymous and we agree with him that shock is the better name of the two, especially as it has been received into several foreign languages. The author discusses the physiology of this condition and shows that the dilatation of the vessels of the splanchnic area, excited by injury to afferent nerves, is the chief cause of shock. The heart is only secondarily affected by the fall in venous blood pressure interfering with its intake. The treatment of shock is given very fully Warmth is of great value but if it is excessive and profuse perspiration is produced the shock will tend to be greatly increased. Position is of importance and the author expresses approval of bandaging the extremities to raise the blood pressure. Stimulants are of use but Mr. Mummery considers that their value in the treatment of shock is often over-estimated. They are best given in small repeated doses and should be combined with some other form of treatment, such as saline transfusion, which will raise the blood pressure. In the author's opinion transfusion is one of the most valuable remedies for the treatment of shock and with this we agree. The needle of an exploring syringe may be used and, as Mr. Mummery points out, it can be passed into the vein through the skin without any preliminary incision. Hæmorrhage after operations, post-anæsthetic complications, and treatment of the wound are also considered. Then follow chapters dealing with operations in special regions of the body, such as the head, the neck, and the abdomen. Each subject is accompanied by a useful little bibliography. An appendix deals with rectal, nasal, and subcutaneous methods of feeding. With reference to the last method the author thinks that in certain cases it may prove useful; "sterilised olive oil seems to give the best results." Diet, massage, exercises, and artificial limbs also receive consideration.

Portfolio of Dermochromes By Professor JACOBI of Freiburg im Breisgau English adaptation of text by J. J. PRINGLE, M.B., C M. Edin., F.R C.P. Lond., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. Parts 3 and 4 London: Rebman, Limited. 1903. Pp. 180 and 80 Plates. Price for the whole work from £2 10*s* to £3 3*s*., according to form of binding.—In noticing Parts 1 and 2 of this work we spoke very favourably of the method of reproduction employed and the illustrations in the parts before us in no way fall short of their predecessors. With the issue of these two parts the work is completed. Part 4 deals chiefly with skin affections of syphilis and of other venereal diseases. A work like this appeals not only to those who are specially interested in dermatology but also and even more to those members of the profession who are in general practice and who wish to have coloured plates which may aid them in diagnosing any unusual diseases of the skin with which they may meet. The plates can be obtained loose in a portfolio or bound in various styles.

Anleitende Vorlesungen fur den Operations-Cursus an der Leiche. (*A Course of Operations on the Dead Body.*) Von Professor E. VON BERGMANN, Wirk. Geh.-Rath., Generalarzt, und Dr. H. ROCHS, Generalarzt im Königlich Preussichen Sanitats-Corps. II. Theil. Mit 76 Abbildungen. Berlin: Verlag von August Hirschwald. 1903. Pp. 207. Price 4 marks.—This part deals with the operations on the skull, the spine, the thorax, and the abdomen. We find described, somewhat briefly, the chief points of operations as carried out on the dead body and many more operations are included than are usually performed by students in this country; for instance, an account is given of the method of exposing the heart. The book is abundantly illustrated and is very good but its size prevents anything like a complete description of the methods of operating. Still, it should prove useful to a candidate for any of the higher surgical examinations in assisting him to carry out operations on the dead body.

The Complete Law in Nature Unveiled. By F. WARNER JONES, C E. London: *Knowledge* Office. 1903. Pp. 32. Price 1s. 6*d*.—We are not sure how far it is useful to notice a book of this singular description. The author having observed that a drop of water assumes a globular form when falling has confused the phenomena of surface tension with those of gravitation. Inasmuch as Newton did not attempt to assign a cause to gravitation but contented himself with its experimental verification the author takes this loophole to promulgate his own theory of "globulation." Although intended to complete the law of gravitation, the author makes no allusion to the observations of Newton and others on the movements of the heavenly bodies and the results arrived at, nor does he discuss the methods by which they came to these conclusions. The author speaks of the "similarity of construction" to be noticed "not only in our own bodies but throughout all nature" and concludes that this is the result of some great law which he subsequently calls "globulation"; but the necessity of reconciling this with the tendency that most inanimate things have of assuming a crystalline form has been overlooked. Again, in a review of the shortcomings of the law of gravitation we should expect at least a reference to the determinations of the mean density of the earth by Cavendish, Boys, Poynting, and others. His explanation of the circulation of the blood is notably curious.

Traité d'Analyse Chimique Quantitative. Par le Dr. BLAIS. (*Treatise on Quantitative Chemical Analysis.*) Paris: A. Maloine. 1903. Pp. 495. Price 6 francs.—This book is not intended for students but, as the author states, for pharmacists who are often asked to report on the quality of many substances in general use. The author gives preference to volumetric methods of analysis, 20 pages of the first part of the book being devoted to descriptions of determinations with standard solutions of acids and alkalies, whilst two pages suffice for the explanation of gravimetric methods. The second part deals with the estimation of various metals and non-metals and acid radicles, including a good account of recently improved methods for detecting minute quantities of arsenic in foodstuffs or in the organs. In the third part over 100 pages are devoted to the analysis of urine. Not only is the presence of abnormal constituents taken into consideration but also the deviation from average composition exhibited in the amounts of the normal constituents. To this end various co efficients showing these relationships are given and their use is explained. There are several figures descriptive of the microscopical appearance of the different urinary deposits. The remainder of this part is occupied with the examination of milk, beer, and wines. This book should prove very useful for the class for whom it is intended in France, but for English analysts and pharmacists there are trustworthy treatises accessible in our own language. Should anyone working at chemical analysis have in hand a number of French samples he would find the book help him to put his reports in such a form as to be more readily understood by Frenchmen.

Home Nursing. By BERNARD MYERS. London: Baillière, Tindall, and Cox. 1903 Pp 131. Price 2*s.* 6*d.* net —This is a useful little book but we think that Dr. Myers goes rather beyond his definition of home nursing given in the first sentence: "By Home Nursing we mean to imply the care of the sick in their *own homes* by a person who has not had a *proper hospital training.*" The preface, too, states that "this book is written in the hope that it may be of service in guiding an *untrained nurse* in her duties when administering to the sick and dear ones at home" The ideal is excellent but, like most ideals, it will not be attained—in our opinion at least No one can learn nursing, anatomy, or physiology from a book. The book, however, is sound enough in itself and the directions are clearly laid down. Its great use will be for persons far removed from medical aid who must rely on their own resources and it possesses one singular advantage—namely, that it will not tempt the amateur nurse to take *too much* upon herself. Some recipes for sick-room cookery are given which are good except in one point—namely, in the recipe for white wine whey. Dr. Myers says, "Add two wine-glasses of cooking sherry." Now, what is called "cooking sherry" is an abomination. We do not mean to say that Oloroso at 60*s.* a dozen *need* be used but if sherry is not good enough to drink by itself it is certainly not good enough to cook with and more especially in the case of an invalid. There is plenty of *real* sound sherry to
purchased for 30*s.* a dozen or even less.

a struggle with the General Medical Council. This resistance of the London corporations to the central authority appears to us, for reasons which we have given at length,[1] particularly unfortunate, but the care with which the ruling bodies of the corporations had selected and inspected the schools for teaching preliminary subjects was made apparent in the President's speech, and the applause which followed testified to the appreciation by the meeting of the sound intentions displayed. All this shows the discredit into which the violent tactics of the past decade have fallen.

◆

The Fear of Failure.

IN our last issue we dealt in some detail with the evidence adduced at the inquest upon Miss HICKMAN. The verdict emphasised the narrow boundary which separates insanity from an overwhelming sense of fear, and yet in many ways fear is not necessarily an evil. "Early and provident fear is the mother of safety." In these few words BURKE indicated his opinion of the political value of fear and its importance as a stimulus for the adoption of proper precautions. It is probable that every new venture in every walk of life, though instigated by the loftiest aspirations, is nevertheless accompanied by a haunting fear of failure. The greater the departure from the normal dull routine the more oppressing is the sense of fear due to the uncertainty of result. We wish to know the "end of this day's business ere it come." We are anxious to begin and when once fairly engaged upon the enterprise fear may be forgotten, but we have had the moment of panic, during which much courage may have been needed to hide the inner tumult of feeling.

In professional life fear, though repressed, waits largely upon every step. It takes long practice to overcome the fear of failure which is so oppressive to the conscientious efforts of youth. There are numberless pitfalls to be encountered at every turn: the possibility of failure of diagnosis, of failure of nerve at the moment of strain, of failure of some minute precaution upon which may depend the success of an operation and possibly the life of the patient. In a professional sense the fear of failure indicates a realisation of responsibility, and it is probably most acutely felt by those who have conscientiously striven to attain a thorough mastery of their profession, while those with only a moderate degree of academic equipment may be free from it, inasmuch as they do not know that there is any cause for anxiety. It is the knowledge of possible dangers which unnerves those with little practical training—those who could, perhaps, glibly describe serious surgical operations with the utmost minuteness but have never been called upon to demonstrate their powers by the simplest proceeding, those who may have frequently assisted with the greatest efficiency so long as they were carrying out instructions but have never experienced the weight of individual responsibility. The sense of fear does not imply incompetency. It is only the momentary panic which precedes action and it may sometimes arise from a sudden and overwhelming appreciation of the degree of confidence reposed in the individual and the dread lest some untoward circumstance should tend to show him unworthy of the trust. The fear of failure may be due to an inherent modesty, to a spirit of self-depreciation which recognises human limitations without doing justice to the chances of success where others have succeeded. It is the humility which recognises weakness and takes no thought of power; in the realisation that the time of trial has arrived panic may reign, obliterating consciousness of all the arduous steps by which the ascent has been made to the position which at once offers the chances of success or of failure. The moment of panic is probably experienced in every phase of life demanding individual judgment, skill, and action, and it can often only be met by self-control, by restraint, and by watchful care, and still more by turning from gloomy forebodings to the necessities of action, when self is wholly forgotten and the faculties are concentrated upon overcoming difficulties. FANNY KEMBLE vividly described her miseries before her first appearance as JULIET, how she "sat ready for execution" with the palms of her "hands pressed convulsively together," and yet this was the unseen prelude to a performance which roused a tumult of applause and established her fame as an actress After all, it is *le premier pas qui coûte;* when that is safely passed the rest is easy.

In the profession of medicine the first public appearance is necessarily less abrupt than in the life of an actor. In the training of medical students the gradations of increasing responsibility are made by easy stages, in which the rate of advance may scarcely be realised by the individual. As a clerk and as a dresser in the out-patient room and in the wards every step is checked, controlled, and judged by friendly critics who sympathise even while they stimulate to greater exertions, to more earnest work, and to greater self-control. The fear of failure is at this stage of small account compared to the fear of ridicule, the invariable sequel to any thoughtless or careless action or speech, a sequel which is supplied freely by fellow-students even when the teacher in mercy refrains. This chaffing accompaniment, when given and taken in good part, is of immense educational advantage. Under its influence the habit of self-control is gradually acquired until the student is ready to present himself for examinations which end in his qualification, when he may pass into practice or, preferably, become a resident officer at his hospital. It is in the fierce light of the publicity of these resident appointments that the first shock of responsibility, the first real fear of failure, may come, and the shock must come to all, though it may be greatly increased or diminished by individual temperament and by the practical or theoretical character of the previous work. Happily, the junior resident invariably feels that he is sure of the loyal support of his colleagues and of the members of the staff so long as he acts with prudence and so long as he is obviously doing his best Happily, also, he is generally a light hearted and healthy-minded person and, although fear of failure may momentarily possess him, he cheerfully goes on his way doing his duty and earning his reward of kindly praise from the staff when difficulties have been properly and judiciously encountered. Very rarely, indeed, is it found that the fear of failure hampers the work, unless it is a question of temperament, and yet the dire results which in the recent instance followed from yielding to its sway must render everyone connected with a hospital ready to echo the prayer of HENRY V.:—

---

[1] THE LANCET, June 13th, 1903, p. 1650.

> "O god of battles, steel my soldiers' hearts,
> Possess them not with fear."

The Mansion House Council on the Dwellings of the Poor.

WHEN Mr. W. S. GILBERT wrote that "the law is the true embodiment of everything that's excellent" he probably did not expect to be taken too seriously; at any rate he could not have had in mind the attempts of our legislature to deal with the problem of providing sanitary dwellings for persons of limited means. The law has indeed shown itself to be well meaning but its efforts towards reform are hampered by the claims of vested interests, while the demands made upon the energies of Parliament and municipality alike by the strife of party and the struggle for place are excessive. In these circumstances such a body as the Mansion House Council on the Dwellings of the Poor is seen to great advantage, working as it does singly for the advancement of the health of the community, studying all questions relating to housing and sanitation, watching and, if possible, influencing public opinion on these matters, and promoting where practicable Parliamentary action.

The business like report of the council for the year ending June 30th, 1903, has recently been published and affords ample evidence of the necessity for some improvement in the existing methods of coping with overcrowding and the other hygienic shortcomings which discredit modern civilisation. We may take a case which is set forth in detail. According to the report on four occasions between March, 1898, and February, 1899, the attention of the St. Marylebone Vestry was called to a certain Nightingale-street and in the latter month a reply was received by the Mansion House Council to the effect that "the whole street has been condemned under the Housing of the Working Classes Act as unfit for human habitation and the matter is at the present time in the hands of the London County Council." In consequence of this statement a communication was sent to the London County Council and a correspondence was thus initiated which continued up to March, 1902. In May, 1902, the Marylebone borough council was asked to undertake the closing of the premises and it replied that its public health committee had considered the matter which was being fully dealt with. Five months later nothing had apparently been done and a further appeal was therefore made to the County Council. The discussion thus renewed was still proceeding when the report was published. It is stated that in 1900 the County Council "had prepared a scheme under Part 1 of the Housing of the Working Classes Act for the improvement of the area" and a reference to that Act throws a good deal of light upon the cause of the delay. The Act was passed in 1890 and it repealed and consolidated a number of other Acts. Under Part 1 when a sanitary authority wishes to deal with an unhealthy area an "official representation" has to be made to the authority by the medical officer of health of the district or, in certain cases, by a medical practitioner appointed for the purpose by the Home Secretary or the Local Government Board. Being thus prompted the sanitary authority is required to prepare an "improvement scheme" and if it fails in this duty a local inquiry may be ordered by the Home Secretary or the Local Government Board according to whether the property is situated in the metropolis or elsewhere. A scheme having been adopted notice of it has to be given in the local newspapers and to owners, occupiers, and others concerned and then a petition is presented by the sanitary authority to one or other of the higher authorities above mentioned praying for confirmation of the scheme. The confirming authority orders a local inquiry and if satisfied makes a "provisional order" which in due course is introduced as a Bill into Parliament and may, after being referred to a committee, attain the dignity of an Act. This is but a brief outline of the complicated procedure called for but it will suffice to explain why the repeated protests of the Mansion House Council bore so little evident fruit. The action of the council, however, brings out the inadequacy of existing legal methods and in this way should make for reform.

In another field more has been done by the council. At the instance of Mr. N. L. COHEN its executive committee prepared a report suggesting administrative and legislative changes which would accelerate the working of the Housing Acts and this was brought by Mr. CLAUDE HAY, M.P., and Dr. MACNAMARA, M.P., before a meeting of Members of Parliament and other interested persons with the object of securing from all sides of the House support to an amendment of the Acts. The result was the formation of an advisory committee on housing to embody in writing and to communicate to sympathetic Members of Parliament proposals for improvement in the law. This committee, with Sir JOHN GORST, M.P., at its head, at once put itself into communication with the President of the Local Government Board, the issue being the passing without opposition of the Housing of the Working Classes Act, 1903. Among the important provisions of this Act are two upon which the Mansion House Council lays special stress. Of these, the first is the scheme which insures that where 30 or more persons of the working classes are displaced under Parliamentary powers by public companies, school boards, or in the course of public improvements, the displacing authority must consult the Local Government Board and make such provision for rehousing as in the circumstances the Board thinks necessary. The second prohibits landlords from any longer taking advantage of Section 75 of the Housing Act of 1890 which enabled them, in cases where the annual rental did not exceed £20, to contract out of their obligation to see that at the commencement of a tenancy the house was reasonably fit for habitation. The general routine of the council's work shows an equally practical trend. By means of its local sanitary aid committees it has collected and brought to the notice of the sanitary authority for the particular district a large number of cases in which, owing to defective fittings or otherwise, houses were in a dangerous condition. A paid inspector made 3545 visits dealing with 1970 cases, of which 743 were remedied. In addition to this the council has circulated numerous leaflets and other publications dealing with questions of the prevention of disease and a series of Shaftesbury Lectures on public health were delivered by Mr. BUDGETT MEAKIN. Considering the very limited pecuniary resources of the council this is an excellent record only made possible by the gratuitous services of all the chief officers. There is, however, ample work for another paid inspector and the council would gladly welcome an access of annual subscribers of whom those contributing £1 or more become members of the general council. The honorary secretary is Mr. W. F. CRAIES, of 31, Imperial-buildings, Ludgate-circus, London, E.C., and the honorary treasurer is Sir J. C. DIMSDALE, Bart.

◆

The Progress of Experimental Psychology.

NEARLY ten years have elapsed since we drew attention[1] to the first course of lectures on experimental psychology then being delivered in London at University College. A few weeks ago, in our issue of Nov. 7th, we chronicled the recent addition of an experimental psychologist to the physiological staff of the University of Liverpool and the appointment of a lecturer on experimental psychology at King's College, London. During the interval between these announcements the accurate study of mental phenomena has made such continuous progress that experimental psychology may be said to have emerged quite definitely from the metaphysical atmosphere of mental philosophy which formerly enshrouded it. People now recognise that psychology is amenable to scientific treatment, and in a short time the prefix "experimental" will be regarded as superfluous for psychology as it is now for physiology.

It is hardly to be expected that the laboratories for psychological research which have sprung up during the past few years in England should equal in elaborateness those that are to be found abroad, especially in the United States. Nor has psychology been able to attract in this country the large number of original workers who are to be found on the continent, partly because we have hitherto neglected the encouragement of post-graduate research and partly because the value and bearing of the subject are so imperfectly recognised here. But although the laboratories at Cambridge, at King's College, London, and at University College, London, compare so unfavourably with the splendidly-equipped buildings, ranging from eight to 19 rooms, at Columbia, Harvard, Cornell, and other universities, the subject is nevertheless attracting an increasing number of workers in this country. A psychological society has of late been successfully founded and a new journal—the *British Journal of Psychology*—is to make its first appearance next January and will be devoted solely to psychological as distinguished from epistemological research. It is particularly in relation to education and to diseases of the nervous system that psychology must prove to be a valuable helpmate and it is here that we have some progress to report. Even though it be true that teachers are born and not made, they must nevertheless be properly trained. The fate that long ago befell apprenticeships in medicine and surgery is rapidly overtaking the archaic system of pupil teachers in schools. There is a growing feeling that teachers cannot but profit by an acquaintance with the broad lines of mental (and bodily) development of the child, by a training in pedagogical methods and by a knowledge of the psychological principles underlying those methods. Already in at least one university abroad teachers are familiarised during their course of training with cases of feeble intellect, myopia, deafness, chorea, and other defective conditions of the child's nervous system, in order that they may later recognise and direct medical attention to them at the earliest opportunity. For in primary schools, at least, the teacher stands literally *in loco parentis.* With regard to experimental work we have to note continued progress in the researches initiated by EBBINGHAUS upon memory, retentiveness and association, the collection of children's mental experiences by STANLEY HALL, the investigation of eye and hand movements during reading and writing, and the exact study of the reciprocal effects of mental and bodily exercise. These and allied problems when more completely worked out cannot fail either to modify or to give a scientific basis for various pedagogical maxims which have as yet a mere empirical foundation.

There is little fear of exaggerating the close relation between experimental psychology and diseases of the nervous system. It is hardly too much to say that the clinical investigation of every nervous or mental case constitutes a crude experiment in psychology. But such rough-and-ready determinations, adequate as they may be for our present methods of diagnosis and of treatment, are wholly insufficient to throw fresh light on the complex nature of our mental build. Indeed, no one can pretend to investigate pathological affections of the senses with the needful accuracy, or continue such original research as has been undertaken by KRÄPELIN upon the abnormal mental states induced by drugs and disease, unless he has had a far more thorough education in psychological methods than is at present generally offered to medical students. If the time has not come for urging that the intending psychiatrist needs a special training as much as the sanitary expert, we may at least hope that greater facilities and encouragement will soon be afforded for a more thorough training of such students in experimental psychology.

Annotations.

"Ne quid nimis."

THE ROYAL DENTAL HOSPITAL OF LONDON.

THE dental profession in general and the authorities of the Royal Dental Hospital in particular are to be congratulated on the results of their efforts to place the calling and practice of dentistry on a high professional level. The most important factor which has led to this progress has been the better provision of educational facilities and the equipment of an institution in which dentistry can be thoroughly studied in all its branches. Not afraid to face the question of cost and encouraged by the practical support of their own students the authorities at the Royal Dental Hospital may now claim to possess an admirably equipped dental school and hospital with accommodation ample alike for educational and charitable requirements. Since the acquirement of the new and commodious premises in Leicester-square the number of cases of relief amongst the necessitous classes has increased enormously and the committee of management earnestly appeals for donations in order that the debt on the building may be removed and that the excellent efforts to bring relief may not be relaxed for want of funds. Many interesting facts in connexion with this philanthropic work were related by several speakers on the occasion of the annual dinner of the staff and past and present students which was held at the Hotel Métropole on Nov 21st. Mr. F. J. Bennett, who occupied the chair, in proposing the toast of "The Past and Present Students," referred to the excellent relations existing between the students and the staff and took the occasion to make an appeal for the more extended study of the bacteriological problems in connexion with dental subjects, especially in regard to caries of the teeth. He suggested the founding of a professorship of dental bacteriology. The toast was responded to by Mr. G. W. Bateman and Mr. F. Butler, the former putting in a plea for a fuller appreciation of the importance of the mechanical side of dentistry than was at present given, and the latter gentleman expressing the thanks of the students for the opportunities supplied by the efforts of the school committee for studying the theory and learning the practice of dentistry. Mr. J. Bland-Sutton proposed the toast of "The Hospital and School" and congratulated those present on the equipment of the institution. Referring to the question of financial requirements, he said that, after all, it was a good thing to feel the presence of such a necessity because it spurred on those concerned to further efforts. In replying to this toast Mr. Walter Hills gave an interesting sketch of the history of the school and laid stress on the services rendered by Mr. C. Stoneham. The dean of the school, Mr. Morton Smale, also replied and acknowledged the assistance which had been so liberally provided by the students who had received their education at the institution. Mr. W. S. Nowell gave the toast of "The Visitors," to which Mr. J. Murray replied in a short speech in which he referred to the excellent relations existing between the dental and medical schools. A selection of music was given under the direction of Mr. H. Schartau and the proceedings came to a conclusion after Mr. A. Hopewell-Smith had proposed the health of the chairman which was suitably acknowledged.

[1] THE LANCET, Jan. 13th, 1894, p. 102.

THE COMMON COLD.

IT is not long since a discussion of the "common cold" was every week claiming a considerable proportion of the space devoted in THE LANCET to the letters of correspondents. We doubt not that the same subject is prominent once more both in the minds of practitioners and in the emotions of those whom recent wet and cold have made singularly mindful of the unpleasantness and many mysterious qualities of the common cold. However doubtful the influence of chilling the surface of the body may be in the production of other ailments there can be no question as to the importance of the part which it plays in the causation of many colds; although chill alone is not sufficient to cause a coryza, another etiological factor is also necessary. Modern medical teaching eliminates the "chill" from many etiologies of disease in which the medical student of former times was taught to mention it, but in this ailment at least the time-honoured cause must probably be accepted. Many persons can count for certain upon the presence of a "cold" in their systems within a few hours of having experienced a chill. They state that they literally feel themselves catch cold. Whether this feeling merely bears witness to certain predisposing conditions for bacterial infection, as many maintain, or whether the vaso-motor changes underlying the feeling constitute the essential features of a cold, we should be sorry to have to decide. Of the curious susceptibility and disordered state of the vaso-motor system during the presence in the organism of a "cold" we have not much doubt. One noticeable symptom of this we do not remember to have read of until recently. This is the effect which warming a limited region of the body has in producing a chilled sensation of the remainder in the person of a patient who has a cold. If, for instance, having a cold a man sits sideways by a fire so that one leg is especially heated he experiences a chilling over the rest of his person and may even be caused to shiver. The effect is a kind of complement of what happens when a person similarly affected sits in a draught and thus chills part of his body to a degree of temperature lower than that of the rest. It seems equally mischievous to warm a part considerably more than the general surface of the body.

THE LANCASTER MEDICAL BOOK-CLUB.

THIS society has just celebrated its eightieth anniversary. It was formed on Nov. 11th, 1823, at a meeting of medical men in Lancaster. There were present Dr. David Campbell, Dr. Lawson Whalley, Dr. Edwards, Dr. Morton, Mr. J. Smith, Mr. Christopher Johnson, Mr. Howitt, and Mr. Statter. The old minute reads as follows:—

> It was resolved that it is expedient to establish a society to be called the Lancaster Medical Book Club which shall consist of the gentlemen present and such medical gentlemen resident in Lancaster as shall be elected hereafter by a majority of the existing members.

Dr. Campbell was appointed the president and Mr. Johnson the secretary. Dr. Campbell was the chief mover in the foundation of the Dispensary—now the Royal Infirmary—in 1781 Dr. Whalley graduated at the University of Edinburgh in 1804 and was physician to the county asylum. Mr. Johnson was a well-known practitioner who succeeded his father and was followed by his son and grandson in the practice. He was an able Latin scholar and did much good work in the early days of the microscope. Mr. J. Smith was surgeon to the prison from 1822 to 1837. The subscription was "one guinea for the first half year, commencing on St. Luke's day, 1823, and half a guinea for every following half year." At first it was simply a book club and the books were sold at the end of each half year. Amongst the earliest mentioned are Chevalier's Lectures, Guthrie on the Eye, Bichat's Anatomy, and Cooke's Morgagni. The minute books giving a continuous account of its doings are in the hands of the present secretary. In 1827 there is a quaint note "that all expenses which may hereafter be incurred in conducting the dissection of executed criminals shall be defrayed from the funds of the society," and in the accounts about the same time there is a payment of 10*s*. 6*d*. to the court keeper for his attendance at the dissections and later 10*s*. 6*d*. to Bond for dissections, and again "to cash paid door-keeper at Robinson's dissection 3*s*." In this year the first mention is made of a supper which has since been an annual affair. The entry reads: "Fines amounting to £1 2*s*. 11*d*. were collected and by an unanimous vote of the meeting appropriated towards the payment of the supper ordered on the occasion. The evening was spent in the greatest harmony and good order and the party seperated (*sic*) about a quarter before 12 o'clock." Next year we have a resolution that "1*s*. 6*d*. be allowed from the funds of the club towards the waiter," and shortly afterwards we read that "Mr. Johnson having been elected bailiff of the Commons for the borough of Lancaster generously treated the members of the club who were present with a supper, wine, and punch, and the evening was spent in the greatest harmony." After this it became the custom for any member upon receiving an appointment or on getting married to give a supper to his fellow members. The birth of children was marked by the infliction of a fine of two bottles of wine. It is stated that "two bottles of wine were discussed, being fines from Drs. Watson and Moore on the birth of their children." Again, Mr. Langshaw "washed his child's head in two bottles of wine." In 1848, however, the note is more laconic: "Dr. James Johnson paid his fine of two bottles." The medical library was started in 1841 when it was decided "that a medical library be formed and that in future the books, instead of being sold, should be deposited therein." The committee of the infirmary granted the use of the committee room and this kind permission is continued up to the present time. In 1877 meetings began to be held for the discussion of subjects of professional interest. The first paper was given by Dr. Hall on Experience in Midwifery and the next by Mr. Metcalfe Johnson on the Connexion between Insanity and Ganglionic Irritation. The later history of the club contains little of general interest. The members—33 in number—dine, or rather sup, together each year, meetings for general purposes are held as required, and the clinical section meets once a month during the winter.

THE COST OF SMALL-POX EPIDEMICS.

THE admirable letter on vaccination which Mrs. Garrett Anderson, M.D. Paris, honorary secretary of the Imperial Vaccination League, contributed to the *Times* in the early autumn has, we are glad to see, now been reprinted in pamphlet form. In this shape it should prove very useful to those who are endeavouring to spread over the country the truth with regard to the control of small-pox. We are rapidly approaching the time when definite steps must be taken with respect to the Vaccination Act of 1898 and it is earnestly to be hoped that Mr. Long will adopt a vigorous policy which will result in our following in this particular the example of Germany. Mrs. Garrett Anderson's pamphlet is an eminently common-sense document and it brings out with great clearness the need which obtains for general revaccination if we are ever thoroughly to control our small-pox and to reduce our isolation provision to vanishing point. Although the story told in this pamphlet is for the most part an oft-told tale it will, we fear, have to be narrated in plain terms again and again before the lower classes are able to appreciate the fact that primary vaccination practised in infancy is only protective against death and even attack for an uncertain number of years and that if epidemic small-pox is to become a thing of the past revaccination must be generally and systematically performed at or near the age at which the children in our elementary schools are about to terminate their school career. Until this is done we shall continue to employ both primary vaccination and isolation, neither of which is alone sufficient to prevent periodical and extensive outbreaks of the disease which necessitate our maintaining an elaborate system of accommodation for isolation and ambulance provision during non-epidemic times. Mrs. Garrett Anderson deals at some length with the question of expenditure and for the details our readers must be referred to the pamphlet itself. We may, however, add that the capital sums which have been borrowed to provide isolation and ambulance accommodation in respect of London for small-pox alone have amounted in all up to Sept. 30th, 1902, to £902,757. In other sections of the pamphlet the writer deals with (1) the actual sums raised year by year for the upkeep and working of the hospitals and for the maintenance of small-pox patients in epidemic years over and above the current expenditure in non-epidemic years; (2) the cost to the ratepayers of repaying the accumulated debt or capital account and for the current expenditure in epidemic and non epidemic years; (3) the economic loss to the community by the loss of life in an epidemic of small-pox; and (4) the indirect economic losses. In contrast with this expenditure, which is concisely set out in the pamphlet before us, attention is drawn to Germany with its 56,000,000 people where, by means of systematic vaccination and revaccination, epidemic small-pox has been banished from the land. In 1901 there were in Berlin, with over 1,888 848 inhabitants, 15 cases of small-pox with three deaths – two being unvaccinated children and one an adult aged 44 years vaccinated only in childhood. In this connexion it may be mentioned that in Germany primary vaccination is performed at a later age than is the case in this country—i.e., in Germany the child must be vaccinated before the end of the year next after the year of birth, a provision by which any given child may possibly be nearly two years old before being vaccinated. But in Berlin there is no elaborate system of hospital isolation such as obtains in London. The few cases of small-pox which occur in the metropolis of the German Empire are dealt with in the isolation ward of the Charité Hospital. With a generally well-revaccinated population and a people alive to the blessings which science can bestow there is no need to dread the proximity of a few cases of small-pox. It is to be hoped that the President of the Local Government Board will, when Parliament next assembles and he introduces his Bill providing for general revaccination on the same lines as primary vaccination, tell the House in some detail how these things are done in Germany. The highest patriotism is not to extol one's country when she is in the wrong but to persuade her to follow the example of other nations who have already found the light. In the matter of revaccination there are many people who would gladly support Mr. Long in a little of the mailed-fist policy.

ALCOHOL IN TROPICAL CLIMATES.

MAJOR FRIBIG, who has served in the Dutch East Indies since 1879 as an army surgeon, is the author of a paper on the influence of alcohol on Europeans in the tropics which was read recently at Aix-la-Chapelle. Acclimatisation, he says, is the result of a new regulation of the course of the blood by the vaso-motor system. The use of alcohol in a hot climate weakens that system and consequently interferes with the acclimature. Up to 1898 every Dutch soldier serving in the tropics used to receive 100 cubic centimetres of wine daily as part of his ration, but in May of that year General van Heutsz, Governor of Atjeh, reduced the allowance by one-half and, moreover, permitted the men who were so inclined to draw its value in money instead of the liquor. The officers, whose daily allowance was half a bottle of red wine per head, were also given a similar choice. From that moment, continues Major Fribig, the soldiers, stimulated by the example of their officers, became total abstainers in large numbers and exhibited a power of resistance against disease and fatigue, as well as an obedience to discipline, such as never before had been seen during any of the wars and expeditions which had occurred in Dutch India. The sick-rate at once began to fall, a remarkable diminution being observable even within the first three months. Major Fribig, who has been a total abstainer since 1894, used formerly to indulge in siestas but never does so now. The mid-day heat has no injurious effect on him and he is able to work during the afternoon with as clear a brain as in the morning. While he was a consumer of alcohol exercise under the sun's rays used to exhaust him very quickly, leaving him bathed in sweat and completely worn out. Now he can support the hardest outdoor work without blenching; although 46 years old he lately took part in an arduous expedition and was able to perform the longest and most toilsome marches with comparative ease. It was the same with the other abstainers but all who adhered to their wine suffered severely and in many cases broke down altogether. Major Fribig knows a great number of officers and men who continue to consume alcohol but are nevertheless able to carry out their duties efficiently in time of peace. They are therefore looked upon as fit for active service but no sooner are they put to the test of hard work than they succumb.. Their vascular systems are unable to withstand the extra strain; weakness or paralysis of the heart renders most of them absolutely unfit for duty. Many victims of the alcohol habit become moral wrecks, losing all energy and initiative Suicides amongst the troops in Dutch India are invariably consumers of alcohol. Among the diseases which Major Fribig found far more virulent and fatal in non abstainers than in abstainers are palustral fevers, hæmaturia, cholera, dysentery, cirrhosis of the liver, neurasthenia, cephalalgia, syphilis, and surgical injuries. The authorities in Dutch India are fully alive to the importance of the alcohol question. An influential association has been formed for the encouragement of total abstinence. Under its auspices several recreation rooms have been established in which non-alcoholic refreshments alone are sold, and in the principal garrison town a canteen has been opened where the only intoxicating beverage provided consists of a light wholesome beer. As an addendum Major Fribig, in conclusion, quotes the views of the following authorities: Dr. E Rudel, Dr. Hugo Hoppe, Dr. Livingstone, Captain Hutton, Count Götzen, Emin Pasha, Sir Henry Stanley, General Galliéni, and Lord Roberts The list could easily have been extended.

TREATMENT OF EMBOLISM OF THE LIMBS BY IMMEDIATE AND PROLONGED MASSAGE.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Nov. 6th M. Pierre Merklen called attention to the treatment of embolism of the arteries of the limbs by massage—a method suggested to him by Professor Paul Berger who thus successfully treated embolism of the posterior tibial artery. When an artery is obliterated by an embolus a proximal clot forms and extends as far as the nearest branch given off by the artery; a distal clot also forms which is more extensive. If it extends very far it helps to prevent the establishment of the collateral circulation. Hence the indication is to break up the embolus or to drive it towards the periphery and to prevent the formation of the secondary clots. This result may be achieved spontaneously. Under the title "Histoire dramatique des Migrations d'un Caillot" Potain[1] related a case in which an embolus was first arrested at the bifurcation of the aorta, producing complete but transitory paraplegia, on the following day it had reached the external iliac artery, leaving the corresponding limb inert; on the third day it reached the popliteal artery, which was shown by the return of pulsations in the femoral artery and the limitation of the coldness and anæsthesia to the foot, which symptoms were transitory. M Galliard has published a case of embolism of the axillary artery in which there were severe pain in the shoulder and coldness and lividity of the limb; on the third day the pain and circulatory troubles were confined to the hand. The spontaneous disruption of an embolus is possible only when the artery is not entirely obliterated and the volume and consistence of the clot permit it to be carried into narrower channels. Perhaps also the pulsations of the blood help to break up the clot. Deroyer has proposed to break up the clot in embolism of the aorta by intermittent pressure on the bifurcation.[2] M. Merklen related the case of a man suffering from mitral regurgitation which had existed for 22 years. He was suddenly seized with severe pain in one of the lower limbs which became cold and anæsthetic up to a distance of several centimetres above the knee. The pulsations of the dorsalis pedis artery were absent but those of the femoral artery were retained For nearly two hours M. Merklen and a colleague, relieving one another so as to avoid interruption of the process, practised energetic *pétrissage* of the femoral, popliteal, and posterior tibia arteries until the patient declared that he was relieved. The limb was then wrapped up in cotton-wool. On the following day the relief had remained permanent and heat and sensibility had returned to the limb. The circulation evidently was re established, although there were numbness and formication and the pulsation of the dorsalis pedis could not be felt until several months later. The patient regained complete power in the limb. Probably the massage acted by breaking up as well as by moving the embolus which was driven towards the periphery to a point where arterial obstruction did not, thanks to the collateral circulation, interfere with the nutrition of the limb.

STANDARD ELECTRIC CURRENT PRESSURES AND FREQUENCIES.

THE electric currents used in medical practice, including the production of the x rays, being very largely taken from the mains of the various electrical supply companies, many of our readers will no doubt be interested in questions relative to the pressures and frequencies of such currents. At the present time the several electrical lighting and power authorities supply currents at great varieties of pressure and in view of the desirability of obviating this unsatisfactory state of affairs the Engineering Standards Committee, the offices of which are at 28, Victoria-street, Westminster, has made suggestions as to the minimum number of standard pressures which would best meet present commercial requirements and at the same time would utilise to the fullest extent the consumers existing appliances. The committee recommends direct current pressures of 110, 220, 440, and 500 volts, measured at the consumers' terminals, and at the same time it expresses the hope that these pressures will in future be universally adopted by the engineers advising corporations and others distributing electrical energy. On the question of frequencies the recommendations of the committee are (1) that 25 periods per second be the standard frequency for systems involving conversion to direct current by means of rotary converters, for large power schemes over long distances, and for three-phase railway work; and (2) that 50 periods per second be the standard frequency for mixed power and lighting on town-supply mains, for ordinary factory power plants, and for all medium size power plant where rotary converters are not employed.

THE FEATURES OF THE EPILEPTIC AURA AND ATTACK.

DR B. ONUF, assistant physician of the Craig Colony for Epileptics, New York State, has published in the *New York Medical Journal* of Oct. 31st an account of the features of the aura and the attack in epilepsy as studied carefully in 800 patients. The object of this investigation was to ascertain as accurately as possible the various clinical phenomena and the order of their sequence. Dr. Onuf states that the nature of the epileptic attack varied with the patient and that "the picture of the symptoms was not at all that given in the text books, to which he had seen almost as many exceptions as patients" The points to which special attention was paid were the epileptic "cry" preceding a fit, the character of the convulsions, the pupillary changes, the tendon reflexes after the fit, and the state of coma induced by the fit. The epileptic cry which ushered in the fit was really a "low, tremulous groan" and when the ear was accustomed to it the cry was readily recognisable. The pupils were not always dilated during the epileptic attack; sometimes they were contracted and insensitive to light and at other times they reacted to both light and accommodation. The convulsions were generally preceded by the well known epigastric or other sensory aura, the face then grew pale, the eyes rolled upwards, and with a characteristic cry the patient's body and limbs stiffened in a rigid spasm, in which condition he usually fell down. During this stage of rigidity (tonic spasm) the arms were abducted from the body, the elbows were flexed, and the fingers were tightly and stiffly contracted, while the lower limbs were rigidly extended. The state of tonic spasm lasted about 20 seconds or less; then succeeded violent and jerky movements of the limbs, the head, the jaws, the face, and the trunk (clonic spasms) The saliva collected in the mouth and was churned up into a foam by the spasmodic movements of the tongue which was often bitten between the teeth. During the clonic spasms the patients were liable to be thrown out of bed by the violence of the movements and in many cases had been known to sustain a dislocation of the shoulder or other injury from the fall. The clonic spasms did not always equally affect the two sides of the body; asymmetry of spasm was common. At the close of the convulsive stage the patient passed into a condition of moderate or deep coma. In this stage the senses of sight and hearing were abolished and cutaneous sensibility was impaired in proportion to the depth of the coma, being complete when the coma was profound. The knee jerks were liable to be exaggerated immediately after a fit owing to the condition of exhaustion produced by the epileptic discharge in the cerebral hemispheres, during which time the bulbo spinal reflex arc was in a state of temporary over-action as regards myotatic irritability, so that the tendon reflexes for a brief period were exaggerated.

CHARITY AND CIGARS.

ACCORDING to the announcement of a daily contemporary a "famous tobacco planter, cigar and cigarette maker, has made an unparaleled offer," which is that during next month he proposes "to set aside one-fifth of the entire returns emanating from his extensive advertising throughout the country for the benefit of hospitals and charities." "Every smoker has thus an opportunity of obtaining high-class cigars, smoking mixture, or cigarettes at an exceedingly low price, at the same time assisting the most deserving of charities." "The great advantage" that this famous tobacco planter claims for his specialities "is the entire absence of arsenic, as all the tobaccos of his products are grown on his own vast plantations on virgin soil only." We certainly think it desirable that cigars should be free from arsenic but we are not aware that this form of contamination of tobacco is by any means the rule. In our experience the presence of even minute amounts of arsenic in tobacco is very rare. In a paper, however, on New Zealand Cancer Statistics published in the *Polyclinic* for August, 1902, reference is made to the presence of arsenic in the tobacco smoked in New Zealand which is obtained from the United States and in the same number of that journal Mr. Jonathan Hutchinson discusses the question of arsenic, cancer, and arsenic in tobacco, but no definite conclusion appears to be drawn as to arsenical tobacco being the cause of cancer. It is, of course, just possible that the tobacco plant might absorb arsenic from a soil fertilised with chemical manure contaminated with arsenic, such as, for example, "superphosphate." We note that the founder of the scheme alluded to above states in a pamphlet that samples were recently sent to many well-known analysts and to THE LANCET, with the result that "every report said 'no trace of arsenic or other poisonous metals can be traced.'" We did not say this. What we did say was: "We have carefully submitted the cigars to a series of tests for the most minute amount of arsenic, but in no instance was there the slightest evidence of the presence of this poisonous metal"; and introductory to this was the following: "The statement has reached us more than once that tobacco leaf occasionally contains arsenic, but we have never been able to substantiate it." In view of this observation we clearly inferred that the fact of the cigars being free from arsenic was not surprising. As a correspondent has suggested, this enterprising tobacco grower has evidently taken his cue from the experiment of the hospital shopping day. The tobacco grower is, we are confident, a well-meaning man but his method is not free from objection. Far better would it be if the smoker practised self-denial and devoted to charity the money thus saved.

THE WARREN TRIENNIAL PRIZE.

THE Warren triennial prize was founded by the late Dr. J. Mason Warren in memory of his father and his will provides that the accumulated interest of the fund shall be awarded every three years to the best dissertation, considered worthy of a premium, on some subject in physiology, surgery, or pathological anatomy, the arbitrators being the physicians and surgeons of the Massachusetts General Hospital. The subject for competition for the year 1904 is on some special subject in physiology, surgery, or pathology, so that the whole range of medicine is at the disposal of the candidate. A high value will be placed on original work. Dissertations, which must be legibly written and bound so that they can be easily handled, should be sent to Dr. Herbert B. Howard, resident physician at the Massachusetts General Hospital, Boston, before April 14th, 1904. The name of the writer must be inclosed in a sealed envelope. The amount of the prize for the year 1904 will be $500.

FRACTURE OF THE TIBIA AND FIBULA SIMULATING POTT'S FRACTURE.

IN the *Scottish Medical and Surgical Journal* for October Dr. G. T. Beatson has published an important case showing that a fracture of the tibia and fibula may easily be mistaken for Pott's fracture and demonstrating the value of radiography in revealing mistakes in diagnosis which otherwise would never come to light. A youth, aged 18 years, injured his left ankle in falling from a height of 10 or 12 feet. All the characteristic features of an extreme form of Pott's fracture were present. There were considerable swelling from effusion of blood, great outward displacement of the foot, a marked prominence on the inner side of the joint, and backward displacement of the heel. Dupuytren's splint was applied on the inner side of the leg and the deformity apparently was corrected. Two or three days later the foot did not seem to be in normal relation with the internal malleolus. Skiagraphy showed an oblique fracture of both bones of the leg a little above the ankle. Yet there were a prominence on the inner side of the ankle, eversion of the foot, and backward projection of the heel. The prominence, however, was not caused by the internal malleolus but by the lower end of the upper fragment of the tibia, while the eversion of the foot was not caused by displacement of the astragalus but by the foot being carried outwards with the fractured bones. Resection of the ends of the upper fragments of the bones and wiring suggested itself, but the pressure of the splint on the tightly stretched skin, though carefully applied, had caused sloughing. Asepsis could not therefore be guaranteed and suppurative arthritis of the ankle might be produced if an operation was performed. The leg was placed on a posterior splint with a foot-piece at right angles. Passive movements of the ankle were soon commenced. Five months later the patient could walk well and the movements of the ankle were excellent but there was considerable deformity. Dr. Beatson suggests that some of the cases diagnosed as Pott's fracture in which recovery did not take place with the symmetry which some writers say should always follow were of this nature and that the surgeon was unjustly blamed. The case emphasises the importance of the routine skiagraphy of fractures, even in cases which apparently are characteristic examples of common fractures.

FOOD ADULTERATION IN IRELAND.

THE King's visit to Ireland, the recent Land Act, and to a certain extent the fiscal controversy have again drawn special attention to that really charming country not only as a place for permanent residence but as a unique field for holiday rambling. Sportsmen, admirers of scenery, and students of customs and manners, it is well known, may find much to see and to appreciate, though some times it must be confessed they have to be content to take things rather in the rough. Whilst admitting, however, the claims of Ireland as a health and pleasure resort we must deplore the evidently remiss way in which the adulteration laws are administered. Cases have been brought to our notice in the neighbourhood of a country town not far from Dublin in which visitors were not only overcharged but were supplied with milk deprived of one-half its fat and with 20 per cent. added water—in fact, stuff we might expect to find sold in the slums of a great city and not in a country where the farm is everything—and there is reason to believe that this is a fairly common practice. It is quite clear to anyone with experience of local matters in Ireland that the analytical chemist is not sufficiently in evidence and we think it high time that the Institute of Chemistry should give its attention to the working or non-working of the system of cumulative appointments by which merely a few guineas a year are added to the income of some distinguished man. Skim milk, watery butter, diluted whisky, and numerous other frauds prevail extensively in the country districts. All this might be remedied by each county council appointing an analyst holding the qualification of the Institute of Chemistry (which, by the way, claims authority in Ireland) and providing him with a reasonable field for his duties which they should see were carried out. We are convinced that such appointments would soon check the scandals which we have mentioned and would benefit not only visitors but the inhabitants of the country.

OVERCROWDING IN BETHNAL GREEN.

THE action of the Bethnal Green borough council in prosecuting for overcrowding is to be warmly commended. The council took action against 12 persons, all of them aliens and most of them ignorant of English, under a by-law made by the council under the Public Health (London) Act to prevent overcrowding of sleeping rooms. The state of things revealed by the proceedings bears witness that the borough council cannot be accused of hyper-sensibility with regard to their view of what constitutes overcrowding. In some cases the defendant, tenant of a single room, had sublet the room and men and women were herding together, sleeping sometimes in boxes or on the floor. In one case the tenant, Hyman Inberwitch, occupied a room about 14 feet square by eight feet in height as a sleeping apartment for himself, his wife, another woman, his son aged 19 years, and a girl aged 13 years, there being also a baby some months old. His other room, about 13 feet by eight and a half feet, he also sublet and it was found to be occupied by five adult males. The prosecution resulted in fines, with imprisonment in default, being imposed. The alien population in the Bethnal Green district has absorbed whole streets and the overcrowding evil reached such a point that the borough council appointed extra inspectors and had midnight visits paid with a view to prosecution. It may seem a terrible thing to have to prosecute the very poor for offences which are the direct outcome of the pinch of poverty. The general good, however, must be aimed at and conditions more provocative of all kinds of immorality as well as every species of insanitary evil can hardly be imagined than those which the Bethnal Green borough council has thus determined to quell. Under what conditions can these wretched aliens have lived in their own land if they are willing to exchange them for such terrible circumstances in a strange country?

FIRE AT A BOARD SCHOOL.

ON Wednesday, Nov. 25th, half an hour after the children had begun lessons, the Shaftesbury-road Board School East Ham, was discovered to be on fire. Very fortunately the outbreak of the fire was in a room on the top floor and not at the bottom of the building. On this top floor were 624 boys and the headmaster, Mr. E. Richardson, at once told his assistants to take the boys downstairs into the playgrounds. The boys left in perfect order, as did also 623 girls who were on the floor below and 630 infants who were on the ground floor. The teachers in these two last departments were assisted in getting the children out by a number of policemen. The fire was got under in three hours, the damage being practically confined to the top floor. It is appalling to think of what might have happened had the fire broken out in a ground-floor room or had there been any panic, and the greatest credit is due to all concerned, both children and teachers, for their admirable behaviour in the face of a great danger. Fire is a circumstance which tries the nerves of the strongest, panic is particularly likely to occur, and what panic combined with fire means the records of the Ring Theatre in Vienna, the Paris Charity Bazaar, and the appalling calamity which happened some 30 years ago at a church in Mexico show only too well.

DIARRHŒA AND POLLUTED WATER.

OF late years attention has been called from time to time to outbreaks or epidemics of typhoid fever through contaminated water-supplies, such as those at Maidstone and King's Lynn, but a widespread epidemic of diarrhœa with a serious mortality commencing and ending suddenly as the cause came into operation and was subsequently removed on being discovered, like that recently recorded by Dr. J. C. Thresh, is extremely rare if not almost unprecedented. It commenced suddenly on July 25th of the present year and ended as abruptly on August 25th, having lasted just one calendar month, during which no fewer than 1400 persons of both sexes and all ages and classes were attacked and 14, of whom 13 were young children, died. The area comprised a portion of the borough of Chelmsford and a single village within the limits of the rural sanitary district, each of which derived its water-supply from the same source, in which no other section of the population, urban or rural, shared, and beyond the limits of the incriminated supply there was no excess of diarrhœa. The present year being remarkable for its unusually low diarrhœal death-rate served to emphasise the local incidence. An inspection of the waterworks showed that the supply was derived from several deep wells and distributed over distinct areas. In this particular locality the water was pumped from a deep and unimpeachable well into a small and uncovered reservoir. But the reservoir, instead of being surrounded by a parapet, was not raised above the level of the surrounding ground and was therefore exposed to pollution by surface drainage and the entrance of storm waters during heavy rains. This actually took place in the storm of July 23rd, or two days prior to the occurrence of the first cases, the source of the trouble being evidently an adjoining plot of garden ground manured with road sweepings and the like. Though not followed by such grave consequences the pollution of the tank or reservoir

Members of the College to the Council would give dignity to that body and a president chosen by a council so constituted would indeed be the President of the whole College.

Dr. G DANFORD THOMAS, in seconding the motion, expressed the hope that such a conference as this motion suggested might lead to a settlement of the question. That there were difficulties was no argument against attempting to settle the matter. Both sides might be willing to give way a little in order to arrive at a satisfactory result.

Mr. J. FEARNLEY thought that a deputation would be useless.

The motion was carried *nemine contradicente.*

The third motion, proposed by Dr. W. G. DICKINSON, was as follows :—

> That this meeting regrets the inadequate information given to Fellows and Members regarding the proceedings of the Council and is of opinion that the complete minutes of the Council meetings should be accessible to any Member of the corporation at reasonable hours.

He acknowledged that it was true that an abstract of the minutes of the Council was suspended in the hall of the College in a bad light but this was not sufficient. The details given were not enough, for the Members wanted to know all that the minutes of the Council contained.

Mr. J. BRINDLEY JAMES seconded the motion and urged that the Members would like to know the reasons why the Conjoint Committee decided not to enter into negotiations with the University of London.

The PRESIDENT pointed out that the minutes suspended in the hall were the full minutes of the Council with only such omissions as were absolutely indispensable. With regard to the negotiations about the union with the University of London the full record had appeared in the annual report of the Council. As to inspection of the minutes by any Member of the corporation he might point out that sometimes charges brought against Members of the College had to be considered by the Council and in some cases these charges could not be substantiated and therefore it was very undesirable that such accusations should be made public. With such exceptions as these the full minutes were suspended in the hall. The introducer of the motion had complained that the minutes were placed in a dark corner of the hall ; this was, of course, quite unintentional and if a better position could be found the minutes should be placed there.

After hearing the explanation of the President Dr. DICKINSON requested leave to withdraw the motion. By the permission of the meeting this was done.

In the absence of Mr George Brown Mr. H. NELSON HARDY brought forward the fourth motion :—

> That this meeting considers it unfortunate that the Council should have placed before it their reply to a report from the inspectors of the General Medical Council without publishing at the same time the report itself and further trusts that the Council will take immediate steps to bring the dispute with the General Medical Council to an amicable settlement.

He said that the dispute had now been going on for ten years and it was entirely due to the Council of the College permitting a part of medical education to be carried on in secondary schools.

Mr. J. C. SMITH seconded the motion and expressed the opinion that it was a great pity that the Council of the College should run counter to the opinion of the General Medical Council, the supreme body in medical education. He could see no advantage in any way in the course pursued by the Council of the College and by the Royal College of Physicians of London.

The PRESIDENT thought it would be best if he were to explain the present situation. The Council of the College had always been most careful in what it had done in this matter. It had thought it only reasonable that chemistry, physics, and biology should be studied before passing the preliminary examinations, or at least before the student began his more strictly medical studies, and this arrangement gave him more time to devote to the studies more closely allied to his future work. That this arrangement was really beneficial to the scientific education of the country had been recognised Many eminent scientific men had expressed the highest opinion of the value of the action of the College and one had said that it had contributed greatly to the general study of science in England. The report of the visiting inspectors of the General Medical Council had certainly been unfavourable, but their opinion was still more unfavourable of some other examining bodies. In fact, the general report made by the visitors stated that there was only one examining body which made an approach to a satisfactory attempt at an examination in chemistry and that was the Conjoint Board of England. In its opposition to the action of the General Medical Council the Royal College of Surgeons of England and the Royal College of Physicians of London were absolutely at one.

Mr. COLLINGWOOD opposed the motion, mentioning that in the examinations for the services the percentage of candidates from the College of Surgeons who failed was less than from almost any other examining body.

Dr. DICKINSON thought that as this was a matter affecting the external relations of the College it should have been brought before the Members.

Sir HENRY G. HOWSE said that the Council had been blamed for allowing scientific study to occur before registration but it was really for the benefit of the student. At first the Conjoint Board had recognised those schools which were recognised by the Science and Art Department, but the Council soon began to investigate by personal inspection the recognised schools and many had been struck off the list. The requirements of the Conjoint Board were great and certainly no other examining body took such pains to insure the high character of the teaching bodies it recognised.

When the motion was put to the vote it was lost by 9 votes to 8.

Mr. JOSEPH SMITH then proposed a vote of thanks to the President for presiding at the meeting He also expressed his regret at the death of Sir Robert M. Craven who was a very regular attendant at these annual meetings and suggested that a vote of condolence should be sent to his family.

The PRESIDENT, in acknowledging the vote of thanks, stated that he would carry out the wish of the meeting by conveying to the members of Sir R Craven's family the vote of condolence.

THE INTERNATIONAL SANITARY CONFERENCE.

MEETING IN PARIS.

THE International Sanitary Conference has been working with but little respite for more than a month. The discussions were long and arduous and the result, we are officially informed, is to be kept secret until after Nov. 30th. There now only remains the task of drawing up the text of the agreement which has been accepted in principle. This work is left in the hands of the secretarial staff while most of the delegates have returned to their respective countries but they are all to assemble again in Paris on Nov. 30th To some delegates this opportunity of consulting their Governments is especially welcome. As it was determined that no communication should be made to the press concerning the nature of the debates and the resolutions adopted we cannot guarantee the absolute accuracy of such information as, notwithstanding this determination, we have been able to obtain. Still it would appear that all the proposals made were not adopted. A certain number of resolutions have been unanimously approved and there will be no difficulty in their embodiment as part of the international obligations which it is sought to impose. Then there were other propositions which were approved by all the delegates in principle but to which, nevertheless, some of the delegates did not venture to pledge their Governments. Finally, there were other proposals that were looked upon as so far-reaching and as involving such important issues that a minority of delegates did not dare to vote either for or against them and were anxious to refer these questions to their Governments. In regard to the nature of the problems involved it may safely be said that the measures to be taken to prevent the spread of cholera and plague from country to country held a prominent place. The advanced school of sanitarians has demonstrated more and more conclusively that impediments to communications can be reduced to a minimum ; in other words, strenuous efforts were made to abolish what little remains of the old quarantine practices. But this tendency, it is said, met with energetic resistance on the part of the representatives of Turkey, Greece, and Bulgaria. The Turkish empire has ports on three different seas and a multiplicity of ports that are close to plague-stricken countries. The Greeks plead that they have always enforced quarantine and, with the one exception necessary to prove the rule, have always escaped epidemics. During the Crimean war the quarantine regulations could not be applied and then they had cholera. Ever since the independence of Greece and its constitution as a kingdom the country has not been infected by persons coming from abroad. As for the argument that the period of incubation is only five days and that therefore the passengers and crews are effectively in quarantine during the journey, for the period of danger is over by the time when they arrive in port, this does not apply to Turkey, Bulgaria, and Greece. These countries are farther east and can be reached in less than five days from places where plague exists. Then, again, if one of these three Powers yielded it would be quarantined by the other two. The question of rats as the transmitters of plague was also discussed at length and in this matter unanimity existed. Everyone approved of the measures which it was proposed to take against these dangerous vermin. Then there was a debate on mosquitoes and yellow fever and, finally, it has been recognised that a permanent international sanitary bureau might render considerable service. What would be the precise functions of such an institution has not yet been stated but it is generally agreed that its headquarters should be in Paris. Undoubtedly it would be difficult to find a more pleasant city or one of easier access from all parts of the world.

ASYLUM REPORTS.

Glasgow District Asylum, Woodilee (Report for the Year ended May 15th, 1903).—The average number of patients resident during the year was 890, comprising 468 males and 422 females. The admissions during the year amounted to 280—viz., 139 males and 141 females. Of these 204 were first admissions. Dr. Hamilton C. Marr, the medical superintendent, states in his report that the increase of lunacy in the agricultural district and city of Glasgow is not alarming. "It must be borne in mind that there is a constant flow from the country districts to the city which has a potent influence on the rate of the production of insanity. The young and strong, both in mind and body, seek the city and add to its mental health, leaving behind them, unfortunately, in the country the infirm and incapable. Hence the apparent anomaly in the fact that the Highlands of Scotland have a very much relatively larger insane population than populated districts such as Glasgow, where the causes of insanity are rife." In 31·3 per cent. of the patients admitted there was a history of intemperance. "While the victims of alcoholism are a source of misery and degradation to others, it must be remembered they are often the source of the production of insanity in others. ... .. The idiot, the epileptic, the mentally weak and unstable, are all legacies to his country of the victim of alcoholism." The number of patients discharged as recovered during the year amounted to 128—viz., 59 males and 69 females—or 14·4 per cent. of the average number resident. The deaths during the year amounted to 99, or 11·1 per cent. as calculated on the same basis. Of the deaths eight each were due to epilepsy and cardiac disease, ten to pneumonia, 15 each to senile decay and general paralysis of the insane, 17 to pulmonary and other forms of tuberculosis, and the rest to other causes. The Commissioner in Lunacy states in his report that the patients were well-dressed and suitably provided for, that the wards and day-rooms were bright in appearance, and that the medical case-books were well and carefully kept. A sanatorium for consumptive patients was opened on Dec. 18th, 1902; the buildings are situated in close proximity to the asylum and are lighted by electricity and have all the needful equipment for carrying out the open-air treatment of patients. The committee of management states in its report that two additional farms have been added to the asylum estate to produce sufficient crops to meet the requirements of the institution and to provide for the healthful employment of a larger number of patients.

[illegible]

females. Of these, 142 were first admissions. Dr. D. F. Rambaut, the medical superintendent, states in his report that a large number of patients of both sexes have been usefully employed during the year. "Knitting by machinery has been introduced and mat-making has been commenced, while a sewing room has proved a marked success. A further extension in this direction would prove economical and beneficial to the patients." The health of the institution suffered severely from an epidemic of influenza which appeared in the spring of 1902. 259 patients and many of the attendants were attacked and many patients died from this disease. The infirmary wards proved quite inadequate for the number of those attacked and it was necessary to employ temporarily another assistant medical officer and several attendants. The number of patients discharged as recovered during the year amounted to 83—viz., 40 males and 43 females, or 10·6 per cent. of the average number resident. The deaths during the year amounted to 144, or 18·5 per cent. as calculated on the same basis. Of the deaths two were due to renal disease, four each to epilepsy and pneumonia, five to colitis, seven to cerebral hæmorrhage, 11 to general paralysis of the insane, 13 to senile decay, 14 to pulmonary and other forms of tuberculosis, 18 to cardiac disease, 44 to influenza, and the rest to other causes. The death-rate was the highest ever recorded in the history of the asylum and this was largely due to the severe epidemic of influenza in the spring of 1902. During the year the cost of maintenance of patients per week has been 9*s.* 3¾*d.* per head, as against 8*s.* 11⅛*d.* per week during the previous year. "The increase is due chiefly to the increased price of meat, to the improvement of the dietary of the attendants, and to the reduction of the average number [of patients] resident." The farm and garden account shows a profit of £507 13*s.* as compared with a profit of £243 8*s.* in the previous year. The Commissioners in Lunacy state in their report that the wards and dormitories were, on the whole, in very good condition and well ventilated, that the general health of the institution was good, that the patients were orderly in their behaviour and neat in their dress, that the dietary of the patients was satisfactory both in quantity and quality, and that the medical case-books were well and carefully kept. "The means of combating an outbreak of fire and of securing the escape of patients are by no means satisfactory" and various improvements and alterations are suggested by the Commissioners. The committee of management states in its report that the sum of £498 7*s.* was expended in additions, alterations, and repairs.

Roxburgh, Berwick, and Selkirk District Asylum (Report for the year ending May 15th, 1903).—The average number of patients during the year was 321, comprising 142 males and 179 females. The admissions during the year amounted to 78—viz., 39 males and 39 females. Of these 65 were first admissions. Dr. J. Carlyle Johnstone, the medical superintendent, states in his report that owing to the want of accommodation at the asylum, "admission continues to be refused to all private patients, except in cases of emergency and in cases which would otherwise be placed on the rates and sent in as chargeable to parishes." It frequently occurs that persons who were at first quite willing to pay for their relatives as private patients show a marked unwillingness to contribute anything towards the cost of their maintenance when they have once been admitted as patients of the "pauper" class. Dr. Johnstone is of opinion that provision ought to be made in the district asylum for every case of insanity occurring in the district in which a sum can be paid sufficient to meet maintenance and expenses, with a reasonable addition for interest on capital, deductions being made in deserving and necessitous cases. Hereditary predisposition to mental disorder was ascertained to exist in 45 per cent. of the cases admitted, while in 36 per cent. of the cases suicidal tendencies were present. The physical condition of the patients was "bad in 59 cases and very bad in five cases." In 50 per cent. more or less serious physical disease was present. The number of patients discharged as recovered during the year amounted to 29—viz., 14 males and 15 females, or 9 per cent. of the average number resident. The deaths during the year amounted to 27, or 8·4 per cent. as calculated on the same basis. Of the deaths three were due to senile decay, six each to cardiac disease and general paralysis of the insane, eight to pulmonary and other forms of tuberculosis, and the rest to other causes. The general health of the inmates has, on the whole, been fairly good. Electric lighting has been recently established throughout the building and the brief trials made have given every satisfaction. "The question of the adequacy of protection from fire in the asylum has received the careful consideration of the board of management and it has been decided to carry out various works with the view of making better provision for the escape of the inmates and for checking the spread of fire in the event of an outbreak." The Commissioner in Lunacy states in his report that the asylum was in good order, that the appearance of the wards and day rooms was bright and cheerful, that the patients showed a general appearance of contentment and of kindly and judicious care, and that the medical case-books were well and regularly kept. The committee of management states in its report that the sum of £10,119 4*s* was spent during the year upon the asylum buildings, improvements, furniture, and electric light installation.

MEDICINE AND THE LAW.

A County Court Judge and the Dentists Act.

AT Wellington, Somerset, before his honour Judge Beresford, a point was raised in the course of administration proceedings under section 122 of the Bankruptcy Act, 1883, which the learned judge appears to have treated in a manner fortunately unusual. The individual whose insolvency formed the subject of inquiry was a married man with a family carrying on business as an insurance agent. His debts amounted to £37 18*s*. 2*d*. and among these was scheduled a claim for £4 10*s* by the "English and American Artificial Tooth Company." To the inclusion of this item one of the other creditors, Dr. William Spettigue, a medical man practising at Wellington, objected on the ground that the creditors named were not upon the Dental Register and therefore could not recover for the services in respect of which they claimed. His honour Judge Beresford's criticism upon Dr. Spettigue's letter in which this point was put forward was that "this learned gentleman had better have become a lawyer," and the reporter who chronicles the judicial humour in the local newspaper with the usual parentheses of "laughter" and "more laughter" records that he further said "playfully" to the registrar, "I think you had better impound this letter as one of the curiosities of the court," after which he proceeded to admit the "English and American Artificial Tooth Company" to the list of creditors It would be interesting to know how his honour Judge Beresford would justify himself in holding up to derision a medical man or any other suitor before him because he claimed to be acquainted with the law directly affecting his own profession. It would also be instructive to know upon what grounds the "English and American Artificial Tooth Company" was allowed by the learned county court judge to rank as creditors unless it were upon the ground that it was owed a debt which it could have recovered by legal process. Under the fifth section of the Dentists Act, 1878, "a person shall not be entitled to recover any fee or charge in any court for the performance of any operation or for any dental attendance or advice unless he is registered under this Act or is a legally qualified medical practitioner." In the newspaper report of the incident before us there is no mention of any evidence as to whether the "English and American Artificial Tooth Company" was, in fact, an individual or a corporation or as to whether it was suggested that a "company," either registered or not, can recover for dental work where an individual cannot. There does not appear to be any legal decision placing an association of individuals upon any different footing from a single person in this respect. There is, indeed, the case of the Pharmaceutical Society *v.* the London and Provincial Supply Association,[1] decided by the House of Lords in 1880 in which considerable argument took place as to the use of the word "person" in Acts of Parliament such as the Dentists Act, and in which it was held that whether the word "person" in a statute can be treated as including a corporation must depend upon a consideration of the object of the statute and of the enactments passed with a view to carry that object into force. This, however, was a case in which the Pharmaceutical Society had sued for penalties an association of shareholders registered as a joint stock company, all of them unqualified to deal in poisonous drugs except one, a qualified person, who conducted the business of a druggist on behalf of the others. Having laid down the law with regard to the use of the word "person", as above the House of Lords held that in the case of the defendants the provisions of the Act were sufficiently satisfied by the fact that the person actually dispensing was qualified under the Act. Anyone who considers this case with reference to the matter before Judge Beresford will see that a totally different point was there involved. The Dentists Act provides that a person shall not be entitled to recover for dental work or advice unless he is a duly qualified practitioner. It would stultify the Act if it was held that "persons" could sue for what "a person" could not, and any attempt to evade the Act by suggesting that the subject of the claim was not "an operation," or "attendance," or "advice" should be rigorously scrutinised. The admission of the debt by the insolvent person should not affect the matter, as he might admit as a debt a large sum due under a wager which would swamp most of his estate and thus deprive others of their money. Whatever the reason, however, may have been which caused the objection raised by Dr. Spettigue to be disallowed, he was entitled to considerate treatment. In no circumstances should a judge attempt to cast ridicule upon one, not being a lawyer, who solicits his intervention. Least of all should he do so where the applicant is a member of another learned profession endeavouring to uphold the honourable privileges of his calling in a court of law.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on Nov. 19th, Sir WILLIAM S. CHURCH, Bart., K.C.B., the President, being in the chair.

The PRESIDENT announced that the adjudicators of the Weber-Parkes prize had selected the following subject for the next award in 1906: "The Degree of Infectivity of Pulmonary Tuberculosis and the Administrative Measures desirable for the Control and Treatment of the Disease"

The PRESIDENT also made a statement in reference to the sum which had been left over from the money subscribed for the expenses incurred in the preparations for viewing the procession on the occasion of the coronation of the King. The President had written to Lord Knollys asking him to obtain the King's permission to allow a portrait of His Majesty to be hung in the College. The necessary consent had been graciously given and it was now proposed to consult with Mr. Fildes as to the production of a replica of a portrait of the King painted by that artist and to apply the above-mentioned sum to that purpose. A subcommittee consisting of the President, the Treasurer (Sir Dyce Duckworth), and Dr. G. F. Blandford was appointed to make the necessary arrangements.

A communication was received from a Member of the College offering a sum of money (£500) for the purpose of encouraging investigation into matters connected with tuberculosis, leprosy, plague, and malaria; that for this purpose a lectureship should be established to be styled "The Dr. Horace Dobell Research Lecture on the Ultimate Origin, the Evolution, and Life-history of Bacilli." This generous offer was thankfully accepted by the College. The President, the Registrar (Dr. E. Liveing), and the Treasurer were appointed to act as a committee to confer with Dr. H. B. Dobell as to the means of carrying out the trust.

VACCINATION EXPENDITURE.—The Chard board of guardians has recently presented an appeal to the Local Government Board in reference to the increased cost of public vaccination in the Chard union since the passing of the Vaccination Act. In the four years immediately preceding the passing of the Act 1853 primary vaccinations were made at a cost of £222, whilst in the four years subsequent to the enforcement of the Act 1840 primary vaccinations and 113 revaccinations were performed at a cost of £911 The guardians suggest that the Local Government Board should be empowered by new legislation to decide that "stational vaccination should be allowed" in unions where good vaccination returns have been shown. With regard to the fees paid to public vaccinators the guardians consider that when such fees were fixed it was thought that public vaccinators would be put to considerably more trouble than has proved to be the case.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Manchester.—Dr. J. Niven reports that the Manchester birth-rate for 1902 (33 per 1000) was higher than in any recent years since 1895 while the marriage-rate (18 per 1000) was also above that for either 1900 or 1901. Although these rates have to be considered in conjunction with the fact that in 1901 the birth-rate, owing apparently to the prevalence of arsenical neuritis, was exceptionally low and that the termination of the South African war may have favourably influenced the marriage-rate there is, as Dr. Niven states, ground for the belief that no serious business depression obtained in Manchester during the year under notice. But since 1885 there have been generally in the city an increase in the marriage-rate and a decrease in the birth-rate, a combination of circumstances which in Dr. Niven's view points to a deliberate restriction of reproduction. Such restriction is not found among "the more reckless portion of the community" and the fact that it is exercised by the more prudent classes may be, he thinks, "a serious menace to the quality of the population." As to this question Dr. Niven remarks: "It may be said generally, I think, that while it is permissible for medical men to indicate the means of restricting production where it is impossible to maintain the young family or where the health of the mother is undermined, nothing but harm is to be expected from the general adoption of artificial means. The result will probably be the selection of an inferior population and a failure to respond to the call for increase in population when the demand is urgent" This is very largely the view which is taken by most people who have thought upon this subject and the stationary condition of the population of France is a good illustration of the manner in which the adoption of neo-Malthusian practices may lead to a serious state of affairs in so far as family or national survival is concerned. It was, indeed, against these practices that Zola's "Sterilité" was largely directed. But the question in its general aspects would be very difficult of treatment by the medical profession and the only practicable manner of attacking it seems to be to handicap the small family financially. Dr. Niven furnishes an interesting account of the measures taken in Manchester to control small-pox and he tells us that in order to avoid the aerial convection of the disease every patient in the acute phase of the malady was oiled with a 2 5 per cent. solution of carbolic oil thrice daily. As a result of this measure no case of the disease occurred within half a mile of the hospital. It was not thought necessary in Manchester to render varicella a notifiable disease and Dr. Niven thinks that no harm accrued from the omission. In his view the most important factor in the spread of small-pox in the city was the overlooking of cases in the common lodging-houses. When cases were discovered therein every effort was made to vaccinate the "contacts." In the poorer common lodging-houses the inducement of a shilling answered the purpose but in the better-class establishments the amount was not sufficient. Dr. Niven makes some suggestions as to the lines which future legislative action should follow and he attaches the greatest importance to general revaccination at school ages. It is, as he observes, by this method that the Germans have prevented the disease from becoming endemic in the fatherland. If an Act containing this provision were passed Dr. Niven thinks that the conscience clause might be retained as in the case of primary vaccination but we do not gather that he would extend the provision of this clause to those who have come in contact with small pox. In these circumstances he would not propose to isolate "contacts," the experience of Manchester during the recent prevalence of small-pox not having shown this step to be necessary. With respect to pulmonary tuberculosis Dr Niven reports that during 1902 1275 cases were notified as compared with 1339 in 1901 and 1573 in 1900—i.e., there has been a progressive decrease in the number of notifications received. Of the 1275 cases notified in 1902 667 were Poor law cases, 305 were from institutions, and only 303 were notified by private practitioners. From these figures Dr. Niven infers that the administrative measures adopted somewhat discourage medical practitioners from notifying cases. The remedy for this state of affairs is, he thinks, compulsory notification. Dr. Niven's views with regard to the communicability of pulmonary tuberculosis will always command respect and interest. He thinks it very difficult for any person to avoid inhaling a certain number of tubercle bacilli but he suggests that an amount of infection which would light up the disease in a weakened constitution would have no effect in those of a more robust habit. He, however, inclines to the opinion that even the strongest person may become infected provided a sufficient amount of infection is present. In judging of the most probable sources of infection in any given series of cases he assumes that healthy people only contract the disease after prolonged exposure and that if such exposure has taken place within two years of the onset of the disease it may reasonably be regarded as the cause of the infection. In this manner 406 cases have been grouped as regards infection into "likely" 278, "less likely" 103, and "possible" 25 Doubtless Dr. Niven has an excellent reason for taking this limit of two years but to some it would seem rather a long interval—i.e , it would appear to imply a period of latency over and above that usually occupied in what is termed incubation, and, if once the principle of latency is accepted, and we are far from rejecting it, there would seem to be no reason for limiting the interval to two years. Behring would probably take a different view of the cases grouped by Dr. Niven and he would conclude that in all there were conditions which altered the resistance of the individual in such fashion as to render him a susceptible subject to the infection which he took in with milk at infancy. He would support his thesis by the records of the post-mortem room and by the results of the inoculation with tuberculin of an Austrian regiment, 68 per cent of whom reacted. But far be it from us to dogmatise upon the very difficult problem and all those interested in the subject of tuberculosis—or, indeed, in all matters of public health—should not fail to read Dr. Niven's admirable report.

The City of Sheffield.—Dr. John Robertson, who is to be congratulated upon being appointed to the important post of medical officer of health of the city of Birmingham, has left behind him in Sheffield numerous records of his energy and ability and among these must be expressly mentioned at the present time the compulsory notification of pulmonary tuberculosis. As, therefore, this is the first departure in the direction of compulsory notification of the disease in this country it will be well to furnish our readers with a brief abstract of section 45 of the Sheffield Corporation Act, 1903, which deals with this question The usual provisions as regards notification, payment, and penalty are duly set forth and these provisions are followed by a clause enacting that whenever the medical officer of health certifies that the cleansing and disinfecting of any building would tend to prevent or to check tuberculosis of the lung the necessary work must be carried out either by the occupier (or owner) or by the corporation. But by far the most important subsection in the whole document is that which enacts that "No provisions contained in any general or local Act of Parliament relating to infectious disease shall apply to tuberculosis of the lung or proceedings relating thereto under this section." It will thus be seen that tuberculous subjects are not to be exposed to the same disabilities as are those suffering from the acute exanthemata—i.e , the disease in question is not added to the Infectious Diseases Notification Act but dealt with separately. Obviously, as we have often pointed out, it would be absurd to apply all the disabilities of the Sanitary Acts to persons suffering from a disease which lasts for years and from which a very large proportion of the population suffer. The Sheffield section is to remain in force for seven years when it will, unless continued by an Act of Parliament or a provisional order of the Local Government Board, automatically cease to be operative The measure is, therefore, purely experimental and it will in this sense be watched with the greatest interest by all those who are anxious to bring about the decrease of pulmonary tuberculosis at a rate greater even than it is already declining. Having regard, therefore, to the importance of the year 1902 in so far as tuberculosis is concerned, we append the death-rates from all forms of tuberculosis since 1893, the rates being per 1000.

1893	2·43	1898	1·80
1894	2·11	1899	2·09
1895	2·27	1900	2·03
1896	1·83	1901	2·19
1897	2·01	1902	1·79

Dr. Robertson tells us that the mortality from pulmonary tuberculosis has been reduced in Sheffield nearly 50 per cent. during the last 50 years and he regards this reduction as mainly due to the improved conditions under which the people live, such, for instance, as "better sanitary arrangements, less overcrowding, better lighting and ventilation, less dampness in dwellings, greatly improved conditions of work due to our Factory and Workshops Acts, and much improved food supplies"

The Borough of Brighton.—The town council of Brighton should feel itself under an obligation to its medical officer of health, Dr. A. Newsholme, and its deputy medical officer of health, Dr. T. H. C Stevenson, for the trouble they have taken in preparing a second Brighton life table based upon the mortality experiences of the ten years 1891–1900 A comparison of the teachings of this table with those of the first life table drawn up by Dr. Newsholme from the mortality experiences of the ten years 1881–90 is both instructive and interesting, and, generally speaking, the comparison must be interpreted as complimentary to the administration of the Brighton town council, whether the results be looked on as indicative of its activity in a purely sanitary sense or whether from the standpoint of the material or social welfare of the people of Brighton. In the construction of the life table what is known as the "graphic method" has been employed except for ages 85 and over, for which what is known as the "method of differences" has been utilised. The result is a table which is thoroughly trustworthy for all practical purposes. Taking now a general view of the inferences to be drawn from a comparison of the two Brighton life tables we find in the first place that the *probability of living one year* in 1891–1900 was less in the first year of life than in 1881–90, but on looking further into the figures we discern a difference as regards the sexes. Although in the case of males the probability of survival to the end of the first half year had diminished that during the last half year had slightly increased. Dr. Newsholme attributes this "worsement" largely to the more general adoption of artificial feeding as well as to meteorological influences. In the case of female children the probability of survival was less in both halves of the first year of life in 1891–1900 than in 1881–90 But after the first year of life the picture for the period 1891–1900 is, generally speaking, materially brighter than was that drawn by the statistician from the figures for the preceding decade. As to males the probability of living through each year was greater at all ages save at the periods 20 to 24, 56 to 65, and 73 to 80 From the age of 80 until the end of life, except at ages 87 and 88, this probability has improved. With respect to females the story was more hopeful in 1891–1900 than in the previous decennium, except for the ages 11 to 14 inclusive, at 64 at ages 66 to 72 inclusive, and at ages 87 onwards. The female probability was greater than the male in every year of life except the second and for each of the years from six to 15 inclusive. After 15 the female probability was greater to the eighty seventh year Coming now to the figures dealing with the *number of survivors out of 100,000 born of each sex* at the end of each succeeding year of life the experiences of 1891–1900 are, except for the first year of life, favourable, not only as compared with the Brighton of 1881–90 but also at every year contrasted with the figures for England and Wales, London and Haydock, and the following table relative to the first four years of life will tell its own tale:—

Male Survivors out of 100,000 Born

Age.	Brighton.	England and Wales.	London.	Haydock.
0	100,000	100,000	100,000	100,000
1	83,194	82,861	81,588	78,510
2	79,211	78,467	76 229	—
3	77 503	76 836	74 123	—
4	76,472	75,826	72,794	—

Finally, with regard to the comparison as to the future *expectation of life* at each year of age, the most important of all the lessons of a life table, compared with 1881-90 the male expectation of life at birth had increased in 1891–1900 by 1 34 years and the expectation remained higher than in the previous decade for every age except from 71 to 75 inclusive. Similarly with respect to females the expectation of life at birth had increased 0·94 year and the expectation remained higher until after 63 when it was fractionally lower than the previous period except at ages 71 to 74. As compared with England and Wales as a whole and with London the male expectation of life at birth in Brighton was during 1891–1900 three quarters of a year higher than in the former and nearly four years higher than in the latter (London). These are, briefly stated, the lessons of the second Brighton life table and we congratulate Dr. Newsholme upon the accomplishment of the task and on the results of the research. It would be interesting if a life table of the poorer parts of Brighton could be separately constructed and compared with a similar table for the richer parts of the same town. Or, perhaps better, we should like to see a separate life table constructed for the several London boroughs.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8020 births and 5037 deaths were registered during the week ending Nov. 21st. The annual rate of mortality in these towns, which had been 16·3, 16 2, and 17 9 per 1000 in the three preceding weeks, declined again last week to 17·4 per 1000 In London the death-rate was 16 6 per 1000, while it averaged 17·8 in the 75 other large towns. The lowest death-rates in these towns were 7·1 in East Ham, 9·3 in Hornsey, 9·5 in Southampton, 9·6 in Brighton, 9·7 in Leyton, 10 6 in King's Norton, 10·7 in Bournemouth, and 10 8 in Coventry; while the highest rates were 24 7 in Plymouth, in Devonport, and in Hanley, 25 1 in St. Helens, 25·5 in Preston, 25 9 in Oldham, 27 1 in Stockton-on-Tees, 27·4 in Middlesbrough, and 29 3 in York. The 5037 deaths in these towns last week included 436 which were referred to the principal infectious diseases, against 523, 419, and 432 in the three preceding weeks; of these 436 deaths, 110 resulted from diarrhœa, 106 from measles, 73 from diphtheria, 59 from whooping-cough, 46 from scarlet fever, 40 from "fever" (principally enteric), and two from small-pox. No death from any of these diseases was registered last week in Hornsey, Tottenham, Hastings, Bournemouth, Reading, Burton-on-Trent, King's Norton, Smethwick, Coventry, Stockton-on Tees, or Newport (Mon.); in the other towns the highest death-rates from the principal infectious diseases were recorded in Willesden, Leyton, Devonport, Hanley, Warrington, Oldham, Preston, York, and Merthyr Tydfil. The greatest proportional mortality from measles was recorded in Willesden, Warrington, Bury, Salford, Oldham, York, and Sunderland; from scarlet fever in Northampton, York, and Merthyr Tydfil; from diphtheria in Bermondsey and Grimsby; from whooping-cough in Devonport, Warrington, York, and Merthyr Tydfil; from "fever" in Wallasey and Preston; and from diarrhœa in Hanley, West Bromwich, York, Cardiff, and Merthyr Tydfil. Of the two fatal cases of small-pox registered in these towns last week, one belonged to Nottingham and one to Tynemouth. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 42, 43, and 51 at the end of the three preceding weeks, had declined again to 47 at the end of last week; five new cases were admitted during the week, against 12, five, and 16 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, Nov. 21st, was 1833, against 1828, 1854, and 1824 at the end of the three preceding weeks; 192 new cases were admitted during the week against 199, 224, and 185 in the three preceding weeks. The deaths in London referred to diseases of the respiratory organs and pneumonia, which had been 260, 271, and 339 in the three preceding weeks, declined again last week to 325, and were 22 below the number in the corresponding period of last year. The causes of 46, or 0·9 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, *Leeds*, Hull, Newcastle-on-Tyne, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Sheffield, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal

Scotch towns, which had been 17·0, 15·8, and 17·4, per 1000 in the three preceding weeks, was again 17·4 per 1000 during the week ending Nov. 21st, and was equal to the rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·7 in Paisley and 12·3 in Aberdeen, to 17·0 in Perth, and 20·4 in Glasgow. The 569 deaths in these towns included 20 which were referred to diarrhœa, 13 to measles, seven to diphtheria, seven to whooping-cough, six to "fever," four to small-pox, and four to scarlet fever. In all, 61 deaths resulted from these principal infectious diseases last week, against 62, 53, and 49 in the three preceding weeks. These 61 deaths were equal to an annual rate of 1·9 per 1000, which was 0·4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 33, 15, and 20 in the three preceding weeks, were again 20 last week, and included 11 in Glasgow, four in Aberdeen, and three in Edinburgh. The deaths from measles, which had been 11, 19, and 10 in the three preceding weeks, rose again last week to 13, all of which occurred in Glasgow. The fatal cases of diphtheria, which had been six and four in the two preceding weeks, rose again last week to seven, and included three in Glasgow and two in Perth. The deaths from whooping-cough, which had been seven, six, and four in the three preceding weeks, increased again last week to seven, of which two were registered in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been two, one, and ten in the three preceding weeks, declined again to six last week, and included five in Glasgow. The four deaths from small-pox and two of the four deaths from scarlet fever occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 108, 107, and 129 in the three preceding weeks, further rose last week to 136, and were 15 in excess of the number in the corresponding period of last year. The causes of 23, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·2, 21·7, and 20·9 per 1000 in the three preceding weeks, rose again to 24·5 per 1000 during the week ending Nov. 21st. During the past four weeks the death-rate has averaged 22·1 per 1000, the rates during the same period being 16 3 in London and 16·0 in Edinburgh. The 178 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 26 over the number in the preceding week and included nine which were referred to the principal infectious diseases, against seven, two, and seven in the three preceding weeks; of these, four resulted from diarrhœa, two from diphtheria, two from whooping-cough, and one from "fever," but not any from small pox, measles, or scarlet fever. These nine deaths were equal to an annual rate of 1·2 per 1000, the death-rates last week from the principal infectious diseases being 1·3 in London and 1 1 in Edinburgh. The fatal cases of diarrhœa, which had been four, one, and none in the three preceding weeks, rose again last week to four The two deaths from whooping-cough showed a slight decline from the number in the preceding week. Two fatal cases of diphtheria occurred last week, none having been registered in any of the five preceding weeks. The 178 deaths in Dublin last week included 31 of children under one year of age and 53 of persons aged upwards of 60 years; the deaths of infants showed a slight decline while those of elderly persons were in excess of the number in the preceding week. One death from violence and four inquest cases were registered, and 59, or one-third, of the deaths occurred in public institutions. The causes of nine, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

NEW REGULATIONS FOR THE ROYAL NAVY MEDICAL SERVICE.

THE new regulations for the Medical Department of the Royal Navy have now been made public These regulations will be found in our issue of Sept. 12th, p. 774, and the document now given to the public varies hardly at all from our version. The following two modifications may be noticed. The hospital allowances for naval medical officers at home and abroad, in lieu of provisions for themselves and servants and for fuel and lights, are now granted also to medical officers of the marine divisions and dockyards. This allowance when made to surgeons at Malta is reduced from £ 08 to £70, but servants will be provided there at the public expense. A small modification also occurs in the matter of compulsory retirement. Retirement will be compulsory upon an inspector or a deputy inspector-general of hospitals and fleets "at the age of 60, or at any age, if he has had three years' non-employment in any one rank; or after four years' continuous non-employment in any two ranks combined." The regulations for the compulsory retirement of these officers as published in our columns read "at the age of 60 or at any age if he has not served for five years." The alteration, which is for the benefit of the officers concerned, was made by an order in Council dated Oct 9th, 1903.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeon J. H. Whelan to the *President* for three months' study at Civil Hospital (to date Dec. 1st, 1903). Staff Surgeon J. Bradley to the *Edgar* (to date Dec. 1st, 1903). Surgeon S. H. Woods to the *Jason* on commissioning.

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned gentlemen have been appointed Officers:—William Donald Anderson and Alexander MacLennan to be Surgeons (dated Nov. 20th, 1903).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants to be Captains (dated Nov. 14th, 1903):—W. J. Waters, H. F. Shea, C. E. Fleming, P. J. Bodington, J. F. Whelan, P. S. Lelean, W. H. Odlum, F. A. Stephens, M. G. Sterling, W. M. Power, J T. Johnson, E. F. Q L'Estrange, R B. Black, and T. B. Unwin.

Major H. A. Cummins, C M.G, is held in readiness for service in India early next year. Lieutenant-Colonel A. Baird, retired list, is appointed to the medical charge of the troops at Worcester.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 3rd Durham: Surgeon Lieutenant J H. Hunter to be Surgeon-Captain (dated Nov. 21st, 1903); Surgeon-Major F. W. Sinclair resigns his commission (dated Nov. 21st, 1903).

Rifle: 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant P. J Le Riche to be Surgeon-Captain (dated Nov. 21st, 1903) 3rd (Dundee Highland) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon Captain W. S. Malcolm resigns his commission (dated Nov. 21st, 1903).

THE RETIREMENT OF SURGEON-GENERAL G. J. H. EVATT.

Apropos of the retirement of Surgeon General Evatt, which we announced last week, a correspondent sends us an appreciation of the work of that officer and we endorse all that our correspondent says, though we are unable to find room for his rather long letter. As the writer points out Surgeon-General Evatt had great ability as an organiser and we owe to him in a very great measure the formation of many of the volunteer ambulance corps which recently proved themselves so useful during the late war in South Africa. Then again it is to Surgeon-General Evatt that the Association of Medical Officers of Schools owes its foundation and his efforts to improve the lot of the private soldier were untiring. According to our correspondent a distinguished member of the Royal Army Medical Corps once referred to Surgeon General Evatt in the following words, which we quote as giving an indication of the kind of officer the service has lost. "There is something inhuman about the man. When he was at Netley he was in the wards at 6 A.M., he was there all day, and there at 11 o'clock at night. It's inhuman, and he made more prisoners than anyone. But Netley was never so smart as when Evatt was there." It is a pity that an arbitrary age limit should prematurely stop the effective work of Surgeon General Evatt.

DEATHS IN THE SERVICES.

Inspector General of Hospitals and Fleets Robert Pottinger, R N. (retired), on Nov. 16th, at Abington Villa, Moffat, in

favourable to the movement generally and the Board has *sanctioned expenditure by boards of guardians for the* erection of sanatoriums. With the facts before them it is to be hoped that the managers will be satisfied that there is now such a "general consensus of metropolitan authorities" in favour of the proposal that they should assume the rôle of hospital authority as would justify them in taking action.

The need is great. In the metropolitan workhouses and infirmaries in July, 1900, there were 1562 persons suffering from consumption and more or less a danger to all with whom they were brought into contact. The number is probably not less at the present time. The managers have power to take charge of this class of the sick poor. To enable them to undertake the isolation and treatment of the non chargeable sick poor probably legislation—a single clause Bill—would be necessary. How many sufferers belonging to this class there may be in London is unknown, but very many certainly, as may be inferred from the fact that last year the deaths in London from phthisis were 7621 compared with 2321 from scarlet fever, diphtheria, and continued fevers, the diseases, other than small-pox, now admissible to the managers' hospitals.

For small-pox ample provision has been made at Joyce [illegible] three hospitals erected at [illegible] a million sterling. The [illegible] site have cost about £320 000, have long been standing idle, and I know not to what purpose they could be applied if not converted to sanatoriums. These hospitals, with some necessary modifications and additions, would, it is thought, serve the proposed purpose very well. The site is admirable and in the midst of a beautiful open country, not far from Dartford, and beyond the fog and soot area of London. The two hospitals, "upper" and "lower," stand on high ground; the locality is bracing, the air is pure, the site is dry, and the water-supply and drainage are satisfactory. They are sheltered from the north and east winds and it may be taken as evidence of the general healthiness of the locality and the suitability of the buildings that in 1902 of 3220 convalescents from fever and diphtheria treated at the upper hospital not one died.

The hospitals are quite distinct and perfectly equipped, *the one moreover being practically invisible from the other*, so that classification would be easy. The wards are light and well ventilated, the floor and cubic space being ample. The grounds are well wooded and there is abundant space for any needed extensions, shelters, &c., the site comprising an area of 160 acres. The upper hospital contains some 1040 beds, the lower hospital, the larger part of which has not been brought into use hitherto, having 850 Gore Farm is within easy reach of the metropolis and the managers' motor ambulance could make the journey, to and fro, by daylight in the shortest day.

Enough, I hope, has been said to show that there is good ground for inquiry, and in the public health interests of the inhabitants of London it is to be hoped that the managers will see their way to use these hospitals for consumptives, and so save the greater part of the half a million sterling which you, Sirs, have suggested as the probable expenditure likely to be necessary to enable them "to deal with tuberculosis." THE LANCET has from the beginning of the movement recorded and commended every extension of sanatorium provision and I hope that its support will not be denied to a proposal which, probably, would double the existing accommodation in special hospitals devoted to the isolation and treatment of persons suffering from consumption.

I am, Sirs, yours faithfully,

T. ORME DUDFIELD.

Kensington, Nov. 21st, 1903.

THE BORDERLANDS OF INFECTIOUS DISEASES AND THEIR MANAGEMENT.

To the Editors of THE LANCET.

SIRS,—The profession owe Dr H E J. Biss a debt of gratitude for his able and instructive paper in THE LANCET of Nov 7th, p 1235, on the Borderlands of Diphtheria and Scarlet Fever. In his argument however, he has seen through a pair of *red* coloured spectacles. My readers will rejoice that I have looked through a *yellow* pair of spectacles and if only one of your subscribers will put on a pair of *blue* spectacles we may *arrive at the clear white light of* truth

Dr. Biss has discussed the class of infectious diseases *referred to from the point of view of the physician to* a fever hospital, who has his cases "dumped" down at his door for reception and treatment, knowing little of their previous or future home history. Regarding infectious illness through his red spectacles he finds cases on his hands varying from the perfectly typical text book description, concerning which no doubt can arise, to the slight or anomalous case for which neither he nor any other authority, however renowned, can on arrival on his dumping ground by any possibility find a docketed pigeon-hole. For such a case he ought to have an undocketed pigeon hole at his disposal in which to place the patient until he can either diagnose the disease or keep him isolated until the illness terminates when he can be returned after disinfection to his home. But surely no one would in earnestness say that such a case was a borderland disease. The disease is true enough and breeds true enough; the only thing lacking is the capacity to diagnose it. What is present is, probably, a feeble microbe in an unsuitable soil which has failed to propagate a full-blown specimen and has merely produced such a poor specimen of the disease that it is undiagnosable by all the art at our disposal. But these poor specimens are true samples of the disease, even although we may be unable to recognise the distinguishing characteristics. I have seen single cases of measles, rose rash, chicken-pox, influenza, whooping cough, diphtheria, scarlet fever, and the "fourth disease" that after a lifetime spent in assiduously endeavouring to elucidate them I am ashamed to confess I have failed to diagnose.

Holding, however, a different position from Dr. Biss I have directed the search light through a pair of yellow-coloured spectacles and have had revealed quite a different picture from that seen through his red glasses When an indistinguishable case of disease arises *as a single case* I am obliged reluctantly to admit that I am unable to diagnose it. But it is so infinitely rare for these diseases to occur as single cases in the position I hold that I merely rest on my oars. Meanwhile I place the patient in quarantine in an undocketed pigeon-hole and wait and watch, like Mr Micawber, "for something to turn up" And when the appropriate *period of incubation of the disease has elapsed and I find* his study companion, or one or both of the two boys who sleep next to him in his dormitory or who sit next to him in "form," in chapel, or at meals, infected with the typical text-book description of the disease, I have very little difficulty in removing my patient from the undocketed to a docketed pigeon-hole. I therefore protest that these anomalous atypical cases are not borderland cases of disease, for they breed absolutely true and only too often start a group of characteristic cases of the disease or an epidemic. The impossibility of the diagnosis of a disease we have before us makes it imperative that means should be provided to quarantine the patient until it can be done; or failing diagnosis altogether, isolating until all possibility of the conveyance of infection has passed. *Further, no immediate* definite diagnosis is necessary when an undocketed pigeon-hole is available in which to quarantine the patient until it can be accurately ascertained.

It is a lamentable admission for a late medical officer of a fever hospital to have to make concerning the administration of fever hospitals, that "the constant breaking out of scarlet fever in diphtheria wards and of diphtheria in scarlet fever wards in most instances is traced to some individual the equivocal nature of whose illness had caused its real bearing to be overlooked." There is no borderland about these as they also bred true enough! It is high time that fever hospitals set their house in order and provided quarantine rooms in which their undiagnosed and undiagnosable cases can be pigeon holed until a diagnosis is possible and not place them in wards where they have no right to be incarcerated. The sooner, then, isolation hospitals, which apparently are not isolation hospitals but disease developers, are mended or ended the more creditable will it be for us as a profession and the safer will they be for the public If something is not done to save these most valuable hospitals from themselves by providing single quarantine rooms for cases undiagnosable on entrance, and by arranging convalescent rooms for separating the convalescents from the recent cases of illnesses the public will refuse to enter them and they will be within their rights as citizens.

It *must therefore be clearly set forth* that the poisons which generate infectious diseases *are* "absolute entities," however humiliating it may be that we are unable to distinguish them in individual cases. But they breed true—as true as they have done for many generations of mankind. The plague, extinct with us in the twentieth century, is as virulent where its environment is favourable for its development as it was in the seventeenth century. In a suitable season and in the unprotected small-pox is as severe as it ever was in Jenner's day. Measles and scarlet fever are still identical with Sydenham's description of them. The type may be milder for a time by reason of the protection afforded by its running through generation after generation of the same race of mankind; but only let a favourable season arise, or a virgin community be attacked, and all the mildness of type is scattered to the winds. The diphtheria of to-day, in the absence of antitoxin, is the same as it was in the middle of the eighteenth and the middle of the nineteenth centuries when it commenced its epidemic fatal form in Cornwall on both occasions. If some of the infectious diseases were crossbreeds they would tend, like all crossbreeds, to revert to the original stock, evidence of which is not forthcoming. The gist of the whole matter seems to be merely one of the virulence or the mildness of the attack. Where this is severe its characteristics are manifest enough; where it is slight it may be so devoid of the distinguishing features of the disease that it may be a "toss-up," owing to our ignorance, as to which genus it belongs. But all doubt is removed when a succession of cases arises, among which are those possessing pathognomonic symptoms, showing that it breeds true, and no such case can be a "borderland," but is as typical as the most characteristic if we only had the faculty to unravel it. The hesitation is with ourselves; there is no dubiousness about the disease.

I am, Sirs, yours faithfully,

Rugby, Nov. 14th, 1903. CLEMENT DUKES.

THE DAWN AND RISE OF PHYSIOLOGY.

To the Editors of THE LANCET.

SIRS,—Professor W. Stirling in his address, an abstract of which appears in THE LANCET of Nov. 21st, p. 1418, suggests that a lectureship on the history of medicine should be established in the Manchester University, and no doubt it is very desirable that such a chair should exist in every university. Still, there is another subject which has a greater claim to be taught in every medical school—viz., dietetics. The laity are beginning to recognise the importance of diet not only in the treatment but in the prevention of disease and it ought to receive more attention than it has hitherto done in the medical curriculum. Hydrotherapy is also receiving much more attention in the schools in Germany and America than it used to do and is a subject which we ought also to study in this country. It would be well if the General Medical Council insisted upon an examination in both subjects. I am, Sirs, yours faithfully,

JOHN HADDON, M.D. Edin.

Denholm, Hawick, Scotland, Nov. 21st, 1903.

THE M.D. DEGREE OF BRUSSELS.

To the Editors of THE LANCET.

SIRS,—Dr. P. A. Nightingale is correct in saying that the M.D. degree of Brussels University for practitioners does not confer the right to practise in Belgium (and I am sure few, if any, would wish to as it is already overcrowded with medical men). When I was in Brussels for the examination I made inquiries on this point and amongst others from the British Vice-Consul. He gave me distinctly to understand that certain formalities had to be gone through and permission had invariably been given in the few cases where the request had been made. Excepting for the fact (which, no doubt, is an important one) that the degree if obtained since 1886 is not registrable, holders of it are on an exactly similar footing with those who possess the practitioner's degree from St. Andrews, Durham, and some other universities. One reason is obvious why medical men who desire to hold an M D. degree have recourse to Brussels University in that the above universities insist on a man being at least 40 years of age.

I am, Sirs, yours faithfully,

Canterbury, Nov. 16th, 1903. A. R. HENCHLEY.

To the Editors of THE LANCET.

SIRS,—In reply to Dr. P. A. Nightingale's letter in THE LANCET of Nov. 14th (p. 1395) respecting the value of the M.D. Brux., I have taken his advice and referred the matter to M. Lavachery, secretary to the University of Brussels, and to Dr. M. Greenwood, honorary secretary of the Brussels Medical Graduates' Association in London. As a result of these inquiries I find that (1) the degree does not *officially* confer the right to practise in Belgium, but that if one were to become domiciled there he would have no difficulty in obtaining a State permit to practise without having to undergo any further examination; and (2) the examination for the scientific title of M.D. for foreign candidates is identically the same as that for the legal title for the Belgian students. In the words of M. Lavachery, "Quant aux examens en eux-mêmes, ils sont identiquement les mêmes que ceux qui sont subis par les Belges à titre légal." The only difference between the terms *legal* and *scientific* M.D. is that the former applies to those students who have passed through their whole curriculum at Brussels and the latter to those who only take the final examinations there.

I am, Sirs, yours faithfully,

Westcliffe-on-Sea, Nov. 18th, 1903. N. LEONARD.

RECURRENT OVARIAN CYSTOMA AND ABERRANT ACCESSORY OVARIAN STRUCTURES.

To the Editors of THE LANCET.

SIRS,—In matters controversial there is nothing like a direct negative for clearing the air and showing up the issues in their true perspective. I will answer Mr. J. D. Malcolm's negatives *seriatim.* He says he has long been of the opinion that ovarian tumours are malignant more often than is generally supposed. He is not the only one who holds this opinion which is, I believe, erroneous, and for the following reasons. 1. It is in direct conflict with the carefully compiled mortality statistics of this country and of all countries where reliable records are kept. Thus Dr. Tatham's analysis of the localisation of malignant disease in women, as given in the Registrar-General's sixty-third annual report, shows that of 16,246 women who died from malignant disease in the year 1900 the ovary was the part affected only in 275 cases, or in 1·7 per cent. The United States statistics for the same year show a still smaller proportion of malignant ovarian disease—viz., less than 1 per cent. (0 9). 2. The information furnished by the statistical reports of large hospitals, where cases of this kind are carefully scrutinised and where a considerable proportion are submitted to post-mortem examination, is entirely in accord with that derived from the national statistics. Thus my analysis of 9227 primary tumours in women under treatment in large metropolitan hospitals shows that only 51 (or 0 6 per cent.) were affected with malignant disease of the ovaries. Similarly of 804 primary ovarian tumours only 6·3 per cent. were malignant. Gurlt's analysis of the mortality statistics of the chief Vienna hospitals gives similar results. Of 138 ovarian tumours from the Kelly clinic, submitted to microscopical examination at the Johns Hopkins Hospital, 11, or 8 per cent., were malignant. 3. Now, in strange contrast with this rarity of malignant disease of the ovaries in ordinary circumstances is the great frequency of its occurrence after ovariotomy, which in Spencer Wells's large experience amounted to no less than 36 per cent.

With regard to this last important item Mr. Malcolm says: "My personal experience does not afford any data in support of it." This is not at all surprising. There are so many ovariotomists nowadays that the experience of any one surgeon is seldom large enough to enable him to dogmatise on such a subject. In Spencer Wells's time it was very different; for many years he had a monopoly of ovariotomy in London and he performed far more operations of this kind than any living surgeon has ever done. Moreover, Spencer Wells, besides being a great ovariotomist, was endowed in no ordinary degree with the business-like habit of keeping accurate records of all his cases which he followed up even to the extent of ascertaining the causes of death of those who died many years after operation. It is to this unique record of his personal experience of 1000 completed ovariotomies that those who wish to know the causes from which women die after this operation should refer. On examining this record I have found that of those who recovered after completed ovariotomy 117 had since died, the cause of death being unknown in 29; of the remaining 88 no less than 32 had succumbed to malignant disease, or 1 in 2·75. During the same period I have ascertained that the cancer mortality in the general population among women of the same age was 1 in 15. Thus the cancer mortality was nearly five and a half times greater for those whose ovaries had been removed than for those who had undergone no such operation. Moreover, the proportion of cancer deaths was much greater among those who had undergone double ovariotomy than in those submitted to the unilateral operation.

The experience of other ovariotomists who have followed up the after-history of their completed cases, as Spencer Wells did (Olshausen, Pfannenstiel, and others) is to the same effect. The gynæcological publications of the last quarter of a century literally teem with confirmatory cases, which might be cited by hundreds. But it would take up too much of your valuable space if I were to proceed further in this direction; for the present it must suffice if, in concluding this letter, I call attention to only one other indication of this kind—viz., the proclivity to malignant disease manifested by persons with badly developed, rudimentary, or absent ovaries, of which so many examples have lately been reported (Krug, Stroebe, Krabbel, Neugebauer, Unterberger, Audain, Ladinski, Heinricius, Obolonski, Fehling, Hall, and others). In face of such facts as I have instanced, I submit that it is necessary for those who disbelieve in the frequency of malignant disease after removal of the ovaries to support their denial with something more convincing than a pious opinion and a vague appeal to personal experience.

I am, Sirs, yours faithfully,
Clifton, Bristol, Nov. 21st, 1903. W. ROGER WILLIAMS

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—Regarding my remarks on the causation of the thoracic expansion which follows upon pulmonary relaxation I must again insist that Dr. A. G. Auld[1] fails to interpret them correctly. He makes me say in effect that the passive outward recoil of the thoracic walls (ribs, sternum, and diaphragm) "is not alone able to produce a certain degree of thoracic expansion, without, that is, any aid on the part of the muscles of inspiration." In both my previous letters I explicitly state that such recoil is competent to do so. What I, however, contend is that the expansion thus induced will not end here but that the inspiratory muscles will come into extra play so as to tighten up the pulmonary tissues (which would otherwise be unduly relaxed) and maintain pulmonary suction at the normal. I fear that Dr. Auld and I are little likely to agree on this matter, for it is evident that we have fundamentally different conceptions as to the origin, nature, and meaning of pulmonary suction. I have failed to convince him that this phenomenon originates in, and is throughout life maintained and regulated essentially by, the inspiratory muscles. He admits, it is true, that these muscles take part in establishing the suction immediately after birth but contends that thereafter "the conditions are, in fact, reversed and the inspiratory muscles instead of endeavouring to establish a pulmonary suction are in reality directed rather against it." Surely a strange contention. The effect of the inspiratory muscles in breathing is *to augment suction:* the mean capacity of the chest is greater during breathing than is its capacity at the end of expiration (when we may suppose the inspiratory muscles to cease to act) and therefore suction is in the former case greater than when the chest remains in the expiratory position; from which it is manifest that the inspiratory muscles must throughout life, moment by moment, take a direct and active share in the maintenance of pulmonary suction.

Dr. Auld makes me appear to have laboured under the misapprehension that in stating a mere physiological truism—i.e., that pulmonary suction favours cardiac diastole—I was enunciating a new and original view of my own, for, says he, "the function of the pulmonary suction in facilitating cardiac diastole ...... is surely a well-established fact in pneumono-dynamics." May I therefore be permitted to remind him that I did not confine myself to a bald statement of this well-known fact. I contended that the *essential* function, the *raison d'être*, of pulmonary suction is to help cardiac diastole, not so much of the ventricles as *of the auricles*, and notably *of the right auricle* (which I may here remark is in much more extensive relation with the lung than is the left, as shown by transverse sections of the frozen cadaver), and I further urged that inasmuch as pulmonary suction is essentially dependent upon, and is throughout life vigilantly regulated by, the action of the inspiratory muscles, these latter contribute a constantly active diastolic force, a view which does not, I venture to hope, savour of platitudinism—if I may be allowed the term.

As to the existence of a pulmonary reflex I have, as I said in a former letter, a perfectly open mind, but I am bound to add that much of the evidence advanced by Dr. Auld in its favour seems to me capable of different interpretations from that which he puts upon it. If it is a fact that the fluoroscopic picture shows a local increase of brightness corresponding to the part of the chest wall stimulated we must indeed accept it as strong evidence in favour of the existence of a pulmonary reflex; but when Dr. Auld supports, as he does in his last letter, Dr. Abrams's contention to the effect that the borders of the lung can be made to move more extensively by reflex means than by forcible inspiration, he is accepting as a truth what appears to me to be a physical impossibility. By means of a complete inspiration the borders of the lung are made to travel to the uttermost confines of the pleuræ. How, I would ask, is it possible for them to go further? Assuming, however, that they can by reflex means be made to move thus far, will Dr. Auld still contend that the attendant expansion of the chest can be wholly due to mere passive recoil?

I am, Sirs, yours faithfully,
Wimpole street, W., Nov. 22nd, 1903 HARRY CAMPBELL.

THE WALSALL DISTRICT MEDICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of *Nov. 21st* amongst the Birmingham news (p. 1467) reference is made to an article in the *Midland Medical Journal* on the subject of the secession of the Walsall Medical Society from the Birmingham and District General Medical Practitioners' Union. In that article the Walsall men are attacked rather vigorously and anyone reading it and knowing nothing of the true state of affairs must draw a very uncomplimentary deduction as to the state of things here. As a matter of fact, Walsall has recently been most active in matters of medical reform. The reply to the circular on the subject of touting clubs was that these clubs were almost, if not quite, abolished. The club collector, who formerly went from door to door, gathering pennies and new members for the doctors' clubs, has vanished from the face of the earth. The majority of the medical men in Walsall are holding together to their mutual advantage and Walsall is not by any means in the parlous state that your correspondent thinks, nor in the absolutely deplorable condition suggested by the writer in the *Midland Medical Journal.*

I am, Sirs, yours faithfully,
FRANK G. LAYTON,
Honorary Secretary, Walsall and District Medical Society.
Walsall, Nov. 22nd, 1903.

THE PRESENT POSITION OF ETHYL CHLORIDE.

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of Nov. 7th, p. 1305, a review of a little book[1] which I published just 15 months ago. The review concludes with the remark that ethyl chloride is noticed as a general anæsthetic but "we should judge fails to gain the favour of the writer." Now anyone taking interest in the subject of anæsthetics must be well aware that ethyl chloride has made enormous strides during the past year in this country. It has been very favourably noticed and commented on in nearly every surgical and dental journal in the English language. I myself have contributed a humble quota to the literature of the subject based on a practical experience of some 400 cases and I think that in ordinary fairness the gentleman who wrote the review in question might have qualified his remarks—especially in view of the protracted period of gestation—by adding "at the time the book was written."

I may remark that at that time I was using the gas-ether sequence very largely, both in hospital and private work. I never went out to an anæsthetic case unless I had a small cylinder of nitrous oxide in my bag. During the past six months I have not used nitrous oxide once in surgical work but have invariably employed the ethyl chloride-ether sequence in preference. I use ethyl chloride every day and often many times a day. I regard it as a very valuable addition to the anæsthetist's repertoire and I am quite sure that it has come to stay and will take a front place among anæsthetic agents in the future. It has been used as largely in Edinburgh as in any medical school during the past few months I think. It is used almost exclusively in the ear and throat wards of the Royal Infirmary and also in the dental department latterly. I am also proud to say that on my advocacy a gentleman of much wider anæsthetic experience than myself started using it in one of the Metropolitan hospitals and has since written me with favourable comments.

---

[1] THE LANCET, Nov. 21st, 1903, p. 1462.

[1] A Pocket Guide to Anæsthetics for the Student and General Practitioner, W. Green and Sons, Edinburgh.

What has kept back ethyl chloride has been the lack of a suitable inhaler. There are several very good patterns on the market now, however, and with any of these good results can be obtained. In THE LANCET of June 13th (p. 1677), July 18th (p. 168), and Oct. 17th (p. 1087), special inhalers, all based on much the same principle, were described by Mr. R. H. Jocelyn Swan, myself, and Mr. G. W. B. Daniell respectively, while in the issue of April 4th (p. 952) of this year Dr. W. J. McCardie expresses his preference for Ormsby's inhaler. I notice to-day in the new English edition of Kocher's "Operative Surgery" just published, that the author remarks that he tried ethyl chloride as a general anæsthetic "several years ago with ungratifying results"—this being doubtless due to the use of Breuer's mask (mentioned in a previous paragraph)—a most unsuitable inhaler in every way.

Will you pardon me if at the risk of repetition I sum up in a few sentences the views I have as to the value of ethyl chloride at the present time? 1. It is a pleasant anæsthetic to inhale, extremely rapid in action, very portable, and inexpensive. 2. It compares favourably with nitrous oxide as regards induction of anæsthesia and available period; it produces no cyanosis when used in suitable doses and necessitates the carrying of no heavy and cumbersome impedimenta. The advantage of this to the general practitioner and dentist in the country is obvious. 3. The technique of the administration is very simple. 4. While not as safe as nitrous oxide in the hands of the unskilled we are justified in concluding from the material available that it is safer than ether, all things considered, and much safer than $CHCl_3$ or bromide of ethyl. 5. It can be safely readministered at one sitting, this being a further point in its favour over bromethyl. 6. It is not usually followed by marked after-effects. 7. It is preferable to nitrous oxide when the patient is very young, very old, or anæmic, while those who are suffering from cardiac, renal, or lung affections take it quite well. 8. It is in no way to be preferred to $CHCl_3$ or ether for *prolonged* anæsthesia but may be used with advantage merely to induce anæsthesia which is maintained either with $CHCl_3$ or ether. 9. For minor surgery, throat operations, and the extraction of teeth it is the best anæsthetic available at the present time. 10. Pure ethyl chloride, sold as such, is always preferable to proprietary preparations and to mixtures such as somnoform. 11. In conclusion, I think one of the strongest claims of ethyl chloride to being considered a fairly safe anæsthetic lies in the fact that during the past 12 months it has been experimented with wholesale throughout the country and yet no death has been recorded. I think it quite possible that we may hear of one or two from time to time now as the anæsthetic becomes more widely used, and often by quite unskilled and inexperienced persons, but that should not blind us to the real merits of the drug when used with reasonable precautions.

I am, Sirs, yours faithfully,

Edinburgh, Nov. 25th, 1903. THOMAS D. LUKE.

*** We have already expressed our regret to Dr. Luke for the delay that has occurred in the review of his book. Guides to any progressive branch of science speedily pass out of date.—ED. L.

TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—[illegible]n your issue of Nov. 21st, p. 1416, you publish a clinical l[illegible]ure on Typhoid Fever by Dr. Seymour Taylor which invites criticism. T[illegible] no doubt Dr. Taylor expects, for he admits at the outset that his remarks are based entirely on clinical experience (? 56 cases) and may be erroneous. First as to what Dr. Taylor calls the predisposing causes but which I should prefer to designate the primary etiological factors. I have dealt with the flood theory elsewhere in the paper[1] I had the honour of reading before the Epidemiological Society in April last. This flood theory has received the strong support of two such eminent sanitarians as the late Dr. Corfield and Mr. Shirley F. Murphy, but I contend that the evidence on the whole is against its being more than a minor factor. For instance, do not floods occur as a general rule as much in February as in any other month of the year? Yet the incidence of typhoid fever in London and the Thames Valley is then at its yearly minimum. Dr. Taylor says: "I shall be interested to read the returns of the incidence of enteric fever in the watershed of the Thames during the wet summer and autumn of this year." He can at any rate find the vital statistics of London month by month in your columns, and the returns for October, 1903, are to be found in the same issue of your valuable journal in which appears his own lecture (*vide* p. 1456). He will find there that "the 49 fatal cases of enteric fever were 28 *below* the corrected average number." Again, at the Metropolitan Asylums Board hospitals, "the weekly admissions averaged 44, against 18, 27, and 40 in the three preceding months." Compare these with the weekly admissions in October, 1902, which "averaged 59, against 49, 38, and 63 in the three preceding months."[2] These figures indicate that London, at any rate, has enjoyed a much smaller incidence of typhoid fever this year than last year and I am inclined to think than for many previous years.

On the other hand, these figures lend considerable support to my own theory that the seasonal incidence of typhoid fever is very largely a mere coincidence with the seasonal consumption of infected shell-fish. London has suffered much less this year because of the shell-fish scare created last autumn and winter and the consequent smaller consumption, on the one hand, and the greater efforts put forth by the various metropolitan sanitary authorities, aided by the Worshipful Company of Fishmongers, to keep off the London markets shell-fish from obviously polluted sources, on the other hand. They, of course, have not been entirely successful in this but they have certainly accomplished a great deal, and in my judgment the immediate result is the marked decline in the incidence of typhoid fever. As undoubtedly some polluted shell-fish have been sold in London even this year and, moreover, as visitors to the various seaside resorts have in large numbers indulged in shell-fish while away (returning to develop typhoid fever in the metropolis) the London figures do not yet show the real proportion of typhoid fever due to shell-fish. It is my opinion that a very large proportion of the number of cases which have occurred this autumn are still traceable to shell-fish and that the satisfactory diminution already noted by no means represents the actual proportion of typhoid fever due to shell-fish. Other sources of typhoid fever in the autumn which must not be overlooked are uncooked vegetables and other foods which have been exposed to pollution in some form and perhaps in this direction the flood theory may be of some account.

As to the next primary etiological factor—the soil, or personal factor—there can, of course, be no two opinions as to its being an important one in the individual case, but it can hardly rank as a seasonal factor, the temperature of the human body being about the same all the year round. As to Dr. Taylor's remarks on relapse and recrudescence, I certainly am among those who can dispute his deductions and I can base my own deductions on 110 cases (with only eight deaths, two of these being admitted moribund) under my own care during the last 27 months and 50 additional cases which were under my observation, though not under my personal care, during the same period. I shall publish my own deductions in a separate paper on another occasion, merely stating here that they do not coincide with those of Dr. Taylor.

As to treatment I am very interested in Dr. Taylor's use of pulvis hydrargyri cum cretâ. I venture to think that this drug has probably not only a direct antiseptic action but an even more important indirect antiseptic action in promoting the flow of that natural intestinal antiseptic, bile. I can quite believe that both Dr. John Harley and Dr. Taylor have adopted this method of medication with satisfaction; I have myself employed hydrargyri subchloridum in some of my cases with satisfaction, but I have not made it by any means a routine method. In any case mercury in small doses commends itself to me as a medicament in typhoid fever in the hands of a judicious physician.

[2] THE LANCET, Nov. 15th, 1902, p. 1347.

I am, Sirs, yours faithfully,
J. T. C. NASH, M.D. Edin., &c.,
Medical Officer of Health, Southend-on-Sea, and
Medical Superintendent of the Borough
Fever Hospital.
Nov. 23rd, 1903.

To the Editors of THE LANCET.

SIRS,—I was much interested in reading Dr. Seymour Taylor's clinical lecture on Typhoid Fever published in THE LANCET of Nov. 21st (p. 1410). In speaking of the recrudescence of the fever he makes the remark that a rise of temperature in the later stages of the disease frequently follows the administration of an enema. I have a case in point at present. My patient, with a temperature of 99° F. at the end of the third week *and no action of the bowels for four days*, his illness having been characterised by constipation rather than by diarrhœa, was ordered a simple enema of soap-and-water. During the next 24 hours his temperature rose to 103° and remained such for 12 hours and then dropped to 99°. I offered an explanation at the time that in absence of any other cause the rise of temperature was due to the liberation of toxins owing to the disturbance caused by the enema. Whether this explanation was the right one puzzled me much till I read Dr. Taylor's paper in which he explains the rise of temperature as due to the liberation of toxins.

I am, Sirs, yours faithfully,
Stamford hill, N., Nov. 21st, 1903. W. A. MILLIGAN.

THE SUCCESSFUL TREATMENT OF A FEW CASES OF LUPUS.

To the Editors of THE LANCET.

SIRS,—May I be allowed to comment upon Mr. C. S. Bowker's interesting article, the Successful Treatment of a Few Cases of Lupus, which appeared in THE LANCET of Nov. 14th, p. 1353. I agree that for suitably situated circumscribed patches of lupus complete excision is the most efficient and the quickest method of treating this disease and a linear scar is preferable to a superficial and large scar in all cases. In my hands, like those of Mr. Bowker, cases so treated have been absolutely free from recurrence. I have removed as many as five foci at one time by excision under general anæsthesia. I, however, fail to see the necessity of following up this operation by a course of tuberculin injections, presuming, of course, that all the foci have been completely removed. I should like to ask Mr. Bowker what is his *raison d'être* for the injection of arsenic, as such after-treatment is, in my experience, quite unnecessary. In very extensive and long standing cases of lupus injections of Koch's tuberculin, either the old or the new, when persevered in, have been followed by excellent, and perhaps I may even say brilliant, results, both as regards the cosmetic appearances and the absence of return. I am now largely using the modified Finsen light and the x rays and have seen numerous most satisfactory cures in the hands of other medical men by this means, but I am doubtful if the results obtained by this treatment are superior to those from tuberculin. After the old tuberculin injections the temperature in my cases has occasionally risen to 103° F., but with the new tuberculin I have never, except in the rarest instances, obtained a temperature reaching 101°. The notes lie before me of a most extensive case of lupus involving the whole of the face excepting the top of the forehead, perforating the septum nasi, destroying part of the alæ nasi, affecting the hard palate, and as the results of its old cicatrising action upon the skin practically crippling the use of the right hand. Under Koch's new tuberculin this patient has immensely improved and I know of no single remedy which could have, in so extensive a case, brought about equally satisfactory results.

In my opinion the value of the "light" treatment depends upon its efficacy and painlessness; even children can be easily induced to submit to it until practically cured. The results of "excision" are perfect and speedy; but there are still some very extensive cases of lupus involving perhaps many different parts of the mucous membrane and skin in which the injections of "tuberculin" are of the highest value.

I am, Sirs, yours faithfully,
Wigan, Nov. 17th, 1903. R. PROSSER WHITE.

MEETING OF LICENTIATES OF THE SOCIETY OF APOTHECARIES.

To the Editors of THE LANCET.

SIRS,—Kindly permit me to call attention to a notice which appears in your advertisement columns of a meeting of Licentiates which is to be held at the Apothecaries' Hall, Blackfriars, at 4.30 P.M. on Dec. 1st next.

I am, Sirs, yours faithfully,
Oxford, Nov. 21st, 1903. A. RIVERS-WILLSON.

THE FUTURE OF ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I must decline to wade through the letter in your issue of Nov. 21st, signed "A St. Bartholomew's Man," as I never attach any value to anonymous communications and in this particular one most of the assumptions are incorrect and do not bear upon the point from which I do not intend to be drawn, viz.:—1. Shall St. Bartholomew's Hospital be rebuilt upon Sir Henry Burdett's plan or upon a plan advocated by the medical council, whichever may be the better of the two, at a cost of roughly £600,000, or shall it be altered and tinkered at a cost of £350,000? 2. Is the most richly endowed hospital in the world, possessing an income of about £100,000 per annum (representing at 2½ per cent. a capital of £4,000,000), justified in asking the public for money if the money is not to be well spent and the effects permanent? 3 If the public find the money asked for, are "they" to decide whether the hospital is (1) to be rebuilt or (2) to be altered, or is the treasurer, who is over 70, and *the secretary, who has already exceeded his age-limit*, who practically control and manage the hospital, to do as they may think fit? 4. I desire to obtain, if possible, from the medical staff or council a public and almost unanimous expression of opinion stating whether they are satisfied with the plan put forward or whether they consider more ground essential for the building of a proper hospital.

In conclusion, may I say it is my intention to attend at the public meeting to be held at the Mansion House on Jan. 26th, when the points I have raised will be brought up and the matter finally settled.

I am, Sirs, yours faithfully,
ANDREW MOTION,
Banbury, Nov. 21st, 1903. Chairman of the Cannon Brewery Co.

AUSTRALIAN WINES.

To the Editors of THE LANCET.

SIRS,—THE LANCET of Oct. 24th (p. 1173) contains a very interesting leading article headed, "The Vintage and its Relationship to Health" It is with the following sentences in the first paragraph that we propose to deal.

You state: "The wines produced in our colonies, which are invariably richer and stronger than those produced in France or Germany, would lose much of the crude qualities which are characteristic of them were they left to mature. While these wines, be it said, have many excellent points they cannot at present compete as regards delicacy or *finesse* with the more classic wines of French growth."

In respect to this remark permit us to say that the Australians have not the least intention of competing in types or styles with the wines of France or Germany, of Portugal or Spain, Madeira, Sicily, or any other country in the world. These countries, one and all, produce wines excellent in themselves and specially characteristic. Australian *vignerons* take a similar position and produce wines characteristic of Australia.

No palate worthy that of a connoisseur would mistake the wines of any of these countries. They are separate and distinct in flavour and in characteristics—as distinct also are the wines of Australia. Therefore, in sampling Australian wines will your readers please taste them on their merits; let them consider what to expect from the juice of full ripe grapes produced under sunshine such as is general in

our English climate could never become like the wines of the colder countries we have mentioned and certainly would not compete with the wines of French growth. Why should they? We have from Australia wines more robust, more generous, more fruity, and natural in a greater degree than the so-called natural wines of any other country. Therefore, why compare the wines of one country with those of another? They all have their charm, whether of delicacy and *finesse*, or of fortified vigour on the one hand, or of natural vigour n the case of Australia. Let us, therefore, accept on their merits the wines of each country but not forget that the wines from Australia are no more than they profess to be—natural wines pressed from the finest wine-making grapes in the world.

One other point. Australian vineyards are 12,000 miles away and produce as delicate, as refined, as elegant wines as France has ever sent to England, but distance from the source of production would be one reason why we should not import such light wines into England and another reason is that our lighter, thinner wines come into competition with the vineyards of France and Germany, whereas with our full-bodied, generous, robust wines no country in the world can compete. And these generous wines are, we find during 33 years' experience, the wines most in demand.

We are, Sirs, yours faithfully,
P. B. BURGOYNE & CO.

Dowgate-hill, London, E.C., Nov. 17th, 1903.

PS.—A good description of the Australian wines imported into this country was given some time since in the *Standard* in which it was stated: "The Australian wines ...... are generous, well-flavoured, full of body, rich in bouquet, abounding in memories of the sun which begot them, ... and, like the wines of the ancients, will bear mixing with water."

NOTES FROM INDIA.

A Medical Factory at Nasik.—Volunteers in India ignorant of English.—The Plague Epidemic.

THE scheme for establishing a factory at Nasik in the Bombay Presidency for the manufacture of drugs and other medical stores, which forms part of the general policy of making India as far as possible self-contained and self-providing against possible times of emergency, is now being steadily advanced. Colonel H. St. C. Carruthers, I.M.S., Madras, who was placed on special duty last year to push the scheme forward, has lately been in Simla conferring with the heads of the departments concerned.

Reports made at different times have drawn attention to the poor physique of the majority of volunteers in India. Now recently I hear of the inspector-general calling attention to the fact that many of the men cannot speak the English language and expressing the opinion that they should not have been enrolled. As a matter of fact, many of the

POST-GRADUATE WORK ABROAD.

(BY A SPECIAL CORRESPONDENT.)

VII. NEW YORK.[1]

PRIOR to the year 1882 post-graduate studies were conducted without any well-organised system in the three medical schools of the city. Large numbers of medical men visited the city during the sessions of the schools for the purpose of studying special branches but they found no other opportunities than the attendance upon the regular lectures and an occasional clinical lecture on a particular subject in one of the hospitals. The result was a great waste of time, little really useful instruction of the kind sought, and a strong tendency to seek the advantages of foreign schools. During the period between 1850 and 1882 American medical students thronged the clinics of the schools of Paris and Berlin. Clinical teaching has been of very slow growth in New York. Though clinics can be traced back a century yet that kind of instruction was withheld from the student and given only to the practitioner. The schools, therefore, discarded clinics from their regular course of teaching and only occasional lectures were given to the small number of physicians who visited the hospital wards. With the opening of Bellevue Hospital, the great almshouse hospital of the city, about the year 1846, and the appointment of a staff of young physicians and surgeons who had been trained abroad, clinical teaching began to assume an importance that had never been given to it before. Students of every grade of advancement eagerly attended these lectures and often at the expense of the regular didactic course of the schools. In vain the faculties of the schools endeavoured to counteract the current; the hospital lectures increased in popularity from year to year until the schools were obliged to organise clinics as a part of the general course of daily lectures. It is now apparent that the early clinical lectures at the New York and Bellevue Hospitals were of high order and powerfully aided in dispelling the illusion that such instruction is harmful to the undergraduate. Students and practitioners alike crowded the amphitheatre when Professor Alonzo Olark, Dr. James R. Wood, Dr. Valentine Mott, Dr. Willard Parker, and others of like reputation gave clinical lectures.

The first decided step to systematise post-graduate studies was taken in 1861 by the organisation of the Bellevue Medical College which was established on the grounds of the hospital and its professors were the physicians and surgeons of the hospital. One of the distinguishing features of that school was the regular and systematic daily clinical lectures in the hospital wards. The school was a success from the first and clearly demonstrated to the other schools that the great want of medical students and practitioners was clinical instruction. From this time the schools began to attach more importance to a connexion with hospitals where instruction could be given and to create dispensaries where the poor would find gratuitous treatment and at the same time be subjects for clinical teaching. One of the most noticeable features of this increase of facilities for clinical instruction was the much larger number of medical men in attendance upon the sessions of the schools. As these physicians came from their practices in the country to study special subjects the schools began to add special teachers to their faculties who classified their clinics according to the nature of the diseases of those in attendance, as diseases of the eye and the ear, the skin, the throat and the nose, and so on. This creation of specialties met the wants of practitioners and recent graduates and became very popular, attracting physicians and students in large numbers from all parts of the country. The schools became crowded with these graduates seeking special privileges and so much time was given to the specialties for the benefit of graduates that in some of the schools the undergraduates were in danger of being neglected. This condition led to the agitation of the question of supplementing the regular faculty with a faculty devoted to the specialties and for a time this was a feature of the course of instruction in the schools, being known as didactic and clinical instruction combined. But this arrangement had its disadvantages as the undergraduate course was interrupted daily by the special courses and the post graduate courses lacked that continuity so essential to the needs of the attending practitioners The University Medical College was the first to discuss the propriety of organising an independent post graduate faculty having its [illegible] wn diploma under [illegible] This proposition [illegible] ecial subjects who found it embarrassing to give their courses of lectures in a connected form in unison with the regular undergraduate courses The proposition was not regarded as feasible by the governing faculty and on its refusal to create such a separate post graduate faculty and course of instruction the professors of specialties determined to establish a separate and independent post-graduate school They accordingly resigned in a body and at once undertook the great task of organising a purely post graduate medical school, an enterprise hitherto unknown There were many predictions of its failure on the part of the faculties of the schools which were all hostile to the movement, as if it succeeded it would attract from their numbers that large and increasing class of medical men who annually visited New York to obtain special instruction To counteract the efforts of those engaged in establishing the new school the medical colleges increased their clinical facilities and largely added to their faculties teachers of the specialties

---

[1] No. I. (Paris), No. II. (Berlin), No. III. (Vienna), No. IV. (Budapest), and Nos. V. (Florence) and VI. (Milan) were published in THE LANCET of Sept. 12th (p. 781), Sept. 26th (p. 912), Oct. 17th (p. 1121), Oct. 24th (p. 1194), and Nov. 21st (p. 1465), 1903, respectively.

It was in 1881 and 1882 that this new departure in medical teaching occurred and from this period may be dated the commencement of a new era in the department of medical education in this city Coincidently with the movement to establish the Post Graduate Medical College was the organisation of the New York Polyclinic Medical School and Hospital along the same lines and for the same objects It is now upwards of 20 years since these schools began their operations and it is possible to day to form an opinion of the results of their work It may be premised by stating that they have been eminently successful in all that pertains to attracting large classes, to imparting useful knowledge on all medical subjects taught and in securing financial support Great credit is due to the promoters of these schools, Professor D B St John Roosa of the Post Graduate School and Professor John A Wyeth of the Polyclinic, men of the highest standing in their profession in this country There is no doubt that these schools have been largely instrumental in giving to New York a commanding position as a great centre of medical education

Referring now to the special advantages which the medical schools and hospitals afford for clinical and post-graduate studies in this city the two schools devoted entirely to post-graduate teaching will be noticed first

The New York Post Graduate Medical School and Hospital was organised by the post graduate medical faculty of the University of the City of New York on April 4th, 1882 It is an incorporated body under the laws of the State It has a faculty of 55 professors 25 adjunct professors, and 77 instructors, or a total of 157 The teaching of the school is entirely clinical or demonstrative It has its own hospital with 205 beds, a babies' department with 54 beds, and an orthopædic division with 27 beds It has a large dispensary service in the same building, a maternity in an adjoining building, and a training school for nurses The laboratory is equipped for the most advanced instruction in bacteriology, histology and pathology The anatomical rooms are ample for teaching operative surgery The babies' ward has a special operating room and a roof garden for summer use The aim of the school has been to give personal instruction to the physicians who attend the clinics so that they may be qualified to carry out in their own practices the most approved methods of procedure The practitioner is brought face to face with the patient and allowed to examine personally the case except when such examinati[illegible] would be detrimental to the patient The school [illegible] vely for members of the profession whose creden[illegible] atisfactory to the directors and who have a lega[illegible] actise medicine in the States or countries fro[illegible] y come, undergraduates are not admitted on [illegible] The school year is divided into two distinct terms—viz, the winter and summer, the [illegible] ing from Oct. 1st to June 1st and the latter [illegible] st to Oct 1st The scope of instruction in [illegible] he specialties The total registration for the [illegible] is 639 and the number who have attended the [illegible] it was opened is 8990

The New York Polyclinic Medical School and Hospital was organised during 1881 and opened in 1882 It is chartered by the University of the State of New York Its faculty consists of 29 professors, 13 adjunct professors, 21 lecturers, 28 instructors, and 42 clinical assistants, making a total of 133 There are two terms—viz, a winter term from Sept 15th to June 14th and a summer term from June 15th to Sept 14th, thus the school is in continuous operation. The school has its own hospital with 80 beds and its own dispensary The terms of admission are the same as those of the Post Graduate School and the methods of instruction are similar The number registered last year was 340

The Greater City has four regular medical schools in addition to [illegible] d First, as reg [illegible] r-geons, estab [illegible] It is now the medical department of the University of Columbia It has a faculty of 37 professors and 77 demonstrators and instructors, a total of 114 The clinical advantages to the students are as follows The Vanderbilt Clinic is equipped with all modern appliances for the study and treatment of disease and was attended by 45,338 patients in 1902, the Sloane Maternity Hospital offers exclusive clinical advantages to the students of this school and contains 116 beds The other institutions open to the free admission of students of this school are the New York Hospital 150 beds, Roosevelt Hospital, 238 beds, Bellevue, 900 beds, Presbyterian, 350 beds, St Luke's, 225 beds; General Memorial, 100 beds, New York Foundling Hospitals, 1500 children, Contagious Diseases Hospitals, 200 beds, Babies' Hospital 50 beds; St Mary's Hospital for Children, 120 beds, and Hospital for Ruptured and Crippled, 250 beds This school has thoroughly equipped laboratories for every species of investigation which the student may require The number of students registered last year was 795 and the number of graduates after a four years course was 168

The Cornell Medical College is the Medical Department of Cornell University which is located at Ithaca, a small city some 300 miles from New York It was organised in 1898 and has a faculty of 39 professors and 103 instructors, a total of 142 Its students have admission to hospitals in addition to those of the College of Physicians and Surgeons already mentioned the City Hospital, with 1000 beds, Skin and Cancer Hospital, 100 beds, St Francis Hospital, 230 beds, and St Vincent's Hospital 250 beds The Loomis Laboratory is a five storey building fully equipped for every variety of study The total registration last year was 394 and 60 graduated after a four years course

University and Bellevue Hospital Medical College was founded in 1898 by the union of the University Medical College organised in 1841, and Bellevue Hospital Medical College organised in 1861 The faculty consists of 26 professors and 81 instructors, in all 107 The same hospitals that have been mentioned as furnishing clinical materials for the other schools are open to this school and in addition the Columbus Hospital, the Manhattan State Hospital for the Insane, and the Lying in Hospital The total registration last year was 311 and the number of graduates was 73

The Long Island Hospital is located in the borough of Brooklyn and was organised in 1858 It has a faculty of nine professors and 64 instructors a total of 73 Its clinical facilities consist of the College Hospital with 300 beds, and the following general hospitals to which its students have free access King's County, St John's Brooklyn, Norwegian Williamsburg, Methodist Episcopal, and Brooklyn Eye and Ear The Hoagland Laboratory, thoroughly equipped with all modern apparatus, belongs to the college. The total registration last year was 290 and the number of the graduates 40

It may be stated in conclusion that at the present time the clinical resources of New York, with its 30 hospitals and 75 dispensaries, are inexhaustible These institutions open their doors to the professors and the teachers and allow the materials to be utilised. And it is a gratifying fact that the change in the methods of teaching from mere formal lectures by six or seven professors in each school to the class recitations with a large corps of young men as instructors is stimulating the recent graduates to seek early entrance to the hospitals and the dispensaries for the purpose of becoming teachers The number of teachers in the six schools noticed above is 726 every one of whom has an official connexion with a hospital, a dispensary, or a laboratory. Thus the city is being supplied with an ever-increasing number of high-grade instructors in every department of medicine. Already it is very noticeable that the drift of medical graduates to European schools to study specialties has almost ceased, while the attendance upon the post-graduate schools is yearly increasing.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday Fund: Annual Report.

THE committee reports another satisfactory year's work and notes with much pleasure that with advancing years this fund appears to deepen its hold on the affections and confidence of the charitable public and that the steady growth observable both in the Sunday and Saturday funds in recent years has been well maintained this year. The receipts of the Hospital Sunday Fund for 1903 amount to £6681 13*s.* 11*d.*, as against £6548 2*s.* in 1902. A slight change in the method of distribution has been introduced this year, a proportion of the total receipts being reserved for special grants to institutions whose circumstances seemed to justify special consideration. In no case, however, was the grant to any institution less than that of last year. New grants were made to the Hospital for Cancer and Skin Diseases and to the Samaritan Hospital for Women. The slight increase in the expenses (£53 14*s.* 4*d.*) is due to the extra advertising of Hospital Sunday in the daily local papers. No successor has yet been appointed to the late assistant treasurer and secretary. The committee deeply deplores the loss through death of Mr. John Brancker, Mr. Edward Mounsey, and Sir James Poole and regrets that it loses the services through removal of four ministers of religion. There is a balance in the bank of £231 18*s.*

Hospital Saturday Fund: Annual Report.

At the annual meeting of the Hospital Saturday Fund held on Nov. 20th the report showed that the systematic collections made in the various places of business were steadily increasing. The total amount (exclusive of interest) raised this year was £8045, an increase of £363 over that of the year 1902. The Lord Mayor (who presided) moved the adoption of the report and said that there was no more interesting or important charity organisation in the city than that of the joint Sunday and Saturday Funds. There were those who suggested that the hospitals should be placed on the rates. He for one would certainly deprecate any such scheme and he did not believe that there was any prospect of that coming about. He could not conceive of the damming up of the fountains of charity which, through the medium of those two organisations alone, were responsible for the large sum of £14,000 a year. But he thought the hospitals might very well be relieved from the payment of rates. That was a legitimate object to work for and he thought they might very well take into consideration how they could best bring that about. Those institutions afforded very sensible relief to the rates of the city and he thought that boards of guardians should assist the hospitals by making grants in compensation for those cases which, if such charities did not exist, would be compelled to go to the parish infirmary. The late Lord Mayor (Mr. W. W. Rutherford, M.P.) also advocated some such system in addressing a similar meeting during his year of office (if I mistake not).

Sanitation in West Africa.

At a meeting of the African trade section of the Liverpool Chamber of Commerce held on Nov. 9th a letter was read from Major Ronald Ross, C.B., F.R.S., the director of the Liverpool School of Tropical Medicine, commenting on the reply made by the Colonial Office to the suggestions of the Chamber that a sanitary commissioner should be appointed for West Africa and certain other points in connexion therewith. Major Ross strongly advised a conference between the chambers of commerce interested and the Colonial Office after the return of Sir William McGregor, K.C.M.G., who has made himself thoroughly conversant with the sanitary needs of West Africa. It was resolved to communicate Major Ross's suggestion to the chambers of commerce interested.

Liverpool Deputation to the Colonial Secretary on West African Affairs.

Mr. Lyttelton, the Secretary for the Colonies, received a deputation on Nov. 19th from the African trade section the Liverpool Chamber of Commerce on the subject West African affairs. Amongst the delegates representi the Liverpool School of Tropical Medicine were Profess R. W. Boyce, F.R.S., and Major Ronald Ross. Profe Boyce spoke of the work done by the Liverpool a London Schools of Tropical Medicine in investigation, teac ing, and the organising of expeditions of research a referred to the great results which had come from this mo ment initiated by Mr. Joseph Chamberlain. Major R also addressed the Colonial Secretary in the same directi Mr. Lyttelton, in reply, said that he associated hims strongly with the desire of his predecessor that all practi assistance should be given to the Schools of Tropi Medicine which had done such excellent work.

Sleeping Sickness: Report from the Liverpool Expedition the Congo.

The first report has now been received from the memb of the expedition of the Liverpool School of Tropi Medicine which was sent to the Congo Free State w the coöperation of the King of the Belgians. T expedition reached Boma on Sept. 23rd and it w arranged with the Vice-Governor-General that it shou inspect and report upon the sanitation, from the poi of view of "mosquito prophylaxis," of Boma, Matidi, a Leopoldville. Later, the expedition will proceed to so locality which seems suitable for beginning research wo The Governor and all the State officials were most courte and obliging and offered to help in every way. Quarters ha been supplied in Boma and will be provided in Matidi a Leopoldville by the State and the local State physicia have placed the native hospital, where there are about t cases of sleeping sickness, at the disposal of the expeditio Up to the date of writing the members of the expediti had examined 51 various native hospital cases and ha already performed two necropsies on cases of the diseas A missionary informed the members of the expedition th last year 4000 people died from this disease in the district Watken and it was stated that the depopulation of th country was feared at Bundunda at the confluence of th Kwango and Kassai rivers. Pest camps have been esta lished in various districts in accordance with the Governm orders and cases are isolated in them under the care soldiers as they occur. The Government hopes by the measures to check the spread of the malady. The native in some places at least, have acquired a lively dre of contagion. They are said to refuse to touch th effects of a man who has died from sleeping sickne or to eat with him while alive and cases of the desertion villages in which the disease has appeared are commo The expedition has written to missionaries and has al requested the Government to indicate to it a place in whic there is a large native population among whom sleepi sickness has been endemic and has now become ep demic. It has asked to be informed if it can obta living facilities and if the natives are amenable to th control of the local whites. The expedition will proceed whatever station seems best to fulfil these conditions for th purpose of getting general information concerning th disease. It has drawn up a list of questions on lines ve similar to those sent out by the Royal Society. The Cong State is printing them and copies will be sent to the vario Government officials throughout the Congo, as well as to mi sionaries and trading firms. A further letter, dated Oct 26t has been received by Sir Alfred Jones, K.C.M.G., the chai man of the Tropical School of Medicine, from the membe of the Congo expedition. They state that they were leavin for Matidi on Nov. 1st. The Governor has placed a Stat steamer at their disposal for the trip. They say that th Congo is certainly the right place to go for huma trypanosomes. They have already seen 18 natives—no cases of sleeping sickness—in whose blood trypanosome were found. They promised to send a short report by th next mail. It will deal with the distribution of mosquitoe in Boma, will give their observations up to date on trypano somiasis and sleeping sickness, and will contain an apprecia tion of the conditions existing in Boma from a mosquito mala riapoint of view.

The Royal Southern Hospital: Anniversary Sermon; Appointment of Honorary Physician.

There was a large congregation at St. James's church on Nov. 22nd, on the occasion of the anniversary sermon on behalf of the Royal Southern Hospital. The Lord

Mayor attended in state The pulpit was occupied by the Rev J B Lancelot, M A (the principal of the Liverpool College), who made an earnest appeal for a larger measure of public support of the charity The collection realised £74 9*s* 9*d*, as against £60 13*s* 1*d* last year At the conclusion of the service the Lord Mayor, with whom was the Lady Mayoress, visited the hospital His lordship was numerously and representatively accompanied in the tour of the building, with the arrangements of which he expressed himself much pleased —The election to the post of honorary physician, vacant by the resignation of Dr William Williams, took place to day (Nov 24th) Dr John Lloyd Roberts, honorary physician to the Stanley Hospital, received a majority of votes over the other two candidates and was declared duly elected The electorate (unlike the system of electoral committees adopted at the Royal Infirmary and David Lewis Northern Hospital) consists of subscribers of two guineas and upwards, two lady trustees being allowed to vote by proxy

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

New Workhouse Infirmary at Axbridge

THE Axbridge board of guardians is among the most progressive in the whole country The guardians have recently erected very excellent tramp wards at a cost of £1600, they have lighted their workhouse with electric light at a cost of £850, and a new infirmary connected with the Axbridge workhouse was formally opened on Nov. 14th by Mr Walter Long, the President of the Local Government Board. There is accommodation in the new building for 72 patients and the cost works out at about £120 per bed On each of the two floors there are two 12 bed wards and six two bed wards The amount of floor space per patient is 72 feet and of air space about 1000 cubic feet There are two day rooms provided with wide bay windows on the southern side of the building and along the whole length of this side there runs a verandah the upper portion of which can be utilised as a fire escape There are a small kitchen lift and a larger lift for patients The building is warmed by hot-water pipes and is lighted by electricity At the opening ceremony Mr Long made some remarks in connexion with the care of pauper children, with regard to which he [illegible] est and brightest [illegible] It was difficult [illegible] a workhouse and [illegible] ome independent self respecting citizens and he urged that they should be placed under the normal conditions of childhood where they could lead the sort of life which children in their position would lead if they were in their own homes and with their own parents Instead of continuing a race of paupers we should then be turning out into the world men and women trained and educated in their minds and bodies so as to be useful citizens

Cardiff Infirmary

Two years ago Mr Leonard D Rea the secretary to the Cardiff Infirmary, devised a scheme which has proved eminently successful for the purpose of eliciting sympathy and assistance in procuring structural improvements and additions to the institution Instead of asking for a lump sum the managing committee ascertained the actual cost of various requirements and then placed the different items before the people of Cardiff For example they stated that electric light could be installed for £1000 whereupon the Marquis of Bute sent them that amount for that specific purpose, a pavilion for the electrical treatment of phthisis was estimated to cost £1450 and this sum was forthcoming from an anonymous lady, verandahs for open air treatment could be erected for £700, and Lord Tredegar offered to defray this expenditure There are still requirements not yet carried out which will cost over £5000 including fire extinguishing apparatus to cost £450 indoor telephones to cost £178 laundry improvements £300, and improved cooking and heating apparatus The latest addition is a new accident receiving ward and out-patient dressing rooms given by Mr Thomas Webb of Tunbridge Wells at a cost of over £1000 Mr. Webb was the donor a few years since of a new operating theatre and his last gift has been designed on the same lines so as to be as aseptic as possible The terrazzo flooring, tiled and cemented walls, rounded corners, and absence of ledges offer no resting places for dust and the rooms can be cleaned out with a hose The shelves in use are made of marmorite, a material consisting of plate glass into which colouring matter has been introduced The only adverse criticism that it appears possible to make is in connexion with the inlet ventilators which are quite incapable of being cleaned out and will thus be dust receptacles Leading out of each of the two dressing rooms which are 18 feet square there is a smaller room 18 feet by 9 feet. This very admirably designed addition to the infirmary buildings was formally opened on Nov 18th by Sir John Williams who took the opportunity of advising the establishment of a branch convalescent hospital within a few miles of Cardiff in order to relieve the pressure on the infirmary itself That this or some other scheme of extension is required is evident from the statement that during the past six months there have been 300 patients always awaiting admission to the wards and of the 184 beds in the institution 164 are in occupation

The Incorporated Society of Medical Officers of Health

At a meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health held at Bristol on Nov 20th under the presidency of Mr J Tubb Thomas, medical officer of health of the county of Wiltshire, there was a discussion upon certain aspects of the question of the prevention of tuberculosis Definite resolutions were passed to the effect that it is desirable where practicable to utilise existing isolation hospitals for the isolation of cases of phthisis, that compulsory powers of isolation should not at present be extended to phthisis, and that in principle the compulsory notification of phthisis is desirable Mr C W Vickers, the medical officer of health of Paignton, spoke very strongly as a general practitioner in opposition to this last resolution and declared that if notification were enforced an immense amount of harm would follow

University College, Bristol

The annual meeting of the governors of University College, Bristol, was held on Nov 18th under the presidency of the Bishop of Hereford A satisfactory record for the session 1902–03 was presented. The report referred with "much regret to the death of Professor Joseph G Swayne, who was elected to the first chair of midwifery and on his retirement the title of professor emeritus was conferred upon him in recognition of his long and valuable services" Dr A. B Prowse was elected as representative of the faculty of medicine on the council of the College for the ensuing three years Mr Morris W Travers has been appointed to the chair of chemistry, vice Professor Sydney Young F R S Mr F E Francis, the lecturer in chemistry, has been appointed assistant professor of chemistry

Hospital Sunday Fund in Bristol

A meeting of the friends of the Hospital Sunday Fund in Bristol was held in the council house on Nov 19th the Lord Mayor presiding It was reported that the amount received for the fund in 1903 was £1565 being £45 less than in 1902 This sum had been allocated as follows Royal Infirmary, £609 General Hospital £511, Children's Hospital, £189, Eye Hospital £91, and smaller sums to the Orthopædic Hospital Lock Hospital Eye Dispensary Bristol Dispensary, Clifton Dispensary and the Medical Mission It was decided that the last Sunday in January should be observed as Hospital Sunday in 1904

Royal Army Medical Corps (Volunteers) New Headquarters at Aberdeen

THE Royal Army Medical Corps (Volunteers) has secured new headquarters in the back portion of the Albert Hall Buildings, Aberdeen, entering from Union Wynd Accommodation for office stores &c, has been provided while the corps will have the use of the large hall or of one of the smaller halls in the building on four nights of the week for drill purposes In addition to the office a waiting room has been acquired in which the men may forgather when awaiting the commencement of drill, while the store rooms are commodious and very suitable for the purpose for which they are intended. In these new headquarters the work of the corps will be carried on much more conveniently than at present.

Aberdeen Medico-Chirurgical Society.

The annual meeting of this society was held on Nov. 19th when the following office-bearers were elected for the year. President: Dr. J. Theodore Cash. Vice-President: Dr. George Rose. Secretary: Dr. John Marnoch. Recording secretary: Dr. Ashley W. Mackintosh. Treasurer: Dr. William Findlay. Librarian: Dr. Peter Howie. Members of council: Dr. G. M. Edmond, Dr. D. W. Finlay, Dr. Angus Fraser, Dr. J. Gordon, Dr. Gray, and Dr. George Williamson.

IRELAND.

(FROM OUR OWN CORRESPONDENTS).

Dublin University Biological Association.

THE opening meeting of the Dublin University Biological Association was held in Trinity College on Nov. 19th, when the President, Mr. R. Charles B. Maunsell, delivered the inaugural address on Surgical Intervention in some Gastric Diseases. Mr. Maunsell in the course of his address said that the subject which he had chosen, although practically unknown ten years ago, had already grown to such dimensions that it would be impossible to treat it in an exhaustive manner. Mr. A. W. Mayo Robson proposed that the best thanks of the association be given to the President for his address. He strongly urged the necessity of surgical treatment in gastritis where within a reasonable time medical measures had failed to give relief and pointed out that where 25 per cent. of cases treated medically terminated in death the mortality was only 5 per cent. when surgical methods were adopted. Sir Charles Ball, in seconding the motion, said that a few years ago the surgical treatment of diseases of the stomach might have been discussed in a few paragraphs; to-day it would fill a large volume.

Dinner to Professor D. J. Cunningham, F.R.S.

The past and present students of the medical school of Trinity College gave a dinner at the Shelbourne Hotel on Nov. 19th to Professor Cunningham, who for a number of years had filled the chair of anatomy in that school. He was presented with a massive loving cup of Celtic design. Professor A. E. Dixon presided and a large and distinguished company were present to do honour to the principal guest.

The Belfast Maternity Hospital.

Out of a large number of applicants Dr. R. J. Johnstone has been elected physician to the Belfast Maternity Hospital, in place of Dr John Campbell who has resigned the position of visiting physician.

An Outbreak of Fever at Enniskillen.

There are at present 18 patients in the Enniskillen Fever Hospital suffering from typhoid fever, scarlet fever, or diphtheria, 12 admissions having taken place during the last few weeks. Mr. John Wilson, the medical officer, has reported to the guardians that the responsibility must rest with them as he predicted and stated what was likely to occur to no purpose. The chairman said he would protect the board and would not allow the medical officer or anyone else to jump on it, but he agreed as to the need of a disinfecting chamber.

The Belfast Sewage.

At a meeting of the Belfast harbour board held on Nov. 17th one of the members drew attention to the insanitary state of the Belfast Lough owing to it being the receptacle of the city sewage which, with the ebb and flow of the tide, is simply deposited on the banks of the lough. By an Act passed in 1899 the corporation of Belfast was required to abate this nuisance within three years and it appears that it is constructing bacteria beds to cope with the problem, but it should be stirred up to complete the work without further delay.

Ulster Medical Society.

The annual dinner of the Ulster Medical Society was held in the Medical Institute, Belfast, on Nov. 20th, Dr. John Campbell, the President, being in the chair. There was a good attendance of members. The following were the toasts: "The King," proposed by the President; "The Lord Lieutenant and Prosperity to Ireland," proposed by the President and responded to by Dr. J. R. Davison; Professor J. A. Lindsay gave the toast of "The Irish Medical Association," to which Dr. L. Kidd (Enniskillen), President of that association, replied; "The Queen's College and Belfast Medical School" was proposed by Dr. F. McLaughlin, the President of the Ulster Branch of the British Medical Association, and the President of Queen's College, Dr. J. W. Browne, and Professor T. H. Milroy replied; Mr. P. C. Cowan, C.E., engineer-in-chief to the Local Government Board of Ireland, proposed "Our Distressed Brethren." The last toast was "The President of the Ulster Medical Society," given by Sir W. Whitla, to which the President replied. During the evening Dr. J. E. MacIlwaine, Dr. H. L. McKisack, Dr. J. McHarry, and Dr. Leslie contributed songs.

(FROM OUR OWN CORRESPONDENT.)

Range and Increase of Hearing in Deaf-Mutes.

AT the meeting of the Academy of Medicine held on Nov. 3rd M. Gariel read for Dr. Marage the results of some experiments made at Bourg-la-Reine for developing and measuring the range of hearing in deaf-mutes. 24 children who were perfectly deaf were taken and divided by drawing lots into two groups. The odd numbers served as controls and the even numbers were treated regularly day by day with vibrations from an apparatus which has already been employed in the treatment of deafness due to sclerosing otitis. At the end of six weeks all the children treated could hear the sounds of musical instruments although they had never heard anything before. Three of them could hear phrases pronounced close to the ear and two could follow a conversation with a person speaking at a distance of one metre and without raising the voice. M. Gariel laid stress upon these excellent results and in addition pointed out that hitherto it has been found impossible to express in exact terms the degrees of hearing possessed by deaf-mutes but that now, thanks to a siren (*sirène à voyelles*) invented by Dr. Marage they can be easily ascertained.

A New School for Hospital Nurses.

Among the improvements in hospital administration laid down in the plans which have been drawn up on such a large scale and approved by the municipal council is one for the foundation of a school where those who intend to become nurses will have a thorough training both theoretical and practical, capable of fitting them in every respect for the career which they have chosen. The plans have just been submitted to the municipal council. The buildings will be erected on some vacant land belonging to the Salpêtrière and are designed for 150 students who will be divided into two groups. On the ground floor the management and those in charge of each group will be accommodated. There will also be a lecture theatre, two refectories, recreation rooms, school rooms, and a library. The students will be lodged upon the upper floors and everyone will have a room to herself, of a fair size, well-lighted, and supplied with a lavatory apparatus. The building will be so arranged that the officials in charge will be enabled to exercise constant supervision over the pupils. The total expenses will amount to about 1,000,000 francs.

Pancreatic Opotherapy in Diabetes.

M. Lafitte has recently made some experiments in the treatment of diabetes by pancreatic opotherapy. He chose cases of diabetes with arthritis, of diabetes with wasting, and of simple glycosuria in arthritic patients. He read a paper on the subject at the meeting of the Hospitals Medical Society which was held on Nov. 13th. The results of opotherapy are practically the same as those obtained by the use of fresh raw pancreas. Shortly they are as follows. There exist a certain number of cases of constitutional diabetes which are favourably affected by pancreatic opotherapy. The glycosuria diminishes and may even almost disappear, the hunger and thirst become less, the genital troubles are much improved, and so also is the general health. The same results are obtained by the use of fresh raw pancreas. The gland must be given raw as soon as possible after the death of the animal. This is an absolutely essential condition of success A delay of even a few hours or the application of a very slight degree of heat so modifies the action of the gland as to render it practically useless The improvement in the degree of glycosuria is very fleeting and lasts for barely a week.

The Annual Proportion of Errors in Diagnosis committed by Military Surgeons

When the vote for the War Department came before the Chamber of Deputies the other day a deputy brought up two cases in which he alleged that the military surgeons had failed to recognise diseases in soldiers which were more or less serious The Minister of War gave the following answer The number of military surgeons is 1500 by far the great majority of whom are hard workers and thoroughly conscientious If any carelessness is proved the War Office punishes it severely To give some idea of the annual proportion of possible mistakes the Minister had consulted a medical man, who is also a senator, and had been favoured with the following argument Suppose that in a service of 30 years every military surgeon makes one mistake the proportion of mistakes calculated on the basis of 1500 medical officers, every one serving for 30 years, would be 50 mistakes every year But this figure is above the mark and the number of mistakes tends to grow less and less, for the whole military medical department knows that errors are no excuse and they are supported in this opinion by their feelings of professional honour

Antituberculous Dispensaries

On all sides efforts are being made to combat the terrible plague of tuberculosis both by care of the sick and protection of the healthy. Here are the figures published by the Municipal Bulletin of Statistics in regard to the deaths from tuberculosis per 10,000 inhabitants in those districts of Paris where the antituberculous dispensaries are in working order The mean figures for the district of Clignancourt for the last two and a half years are 43 2 in place of 74 2 which was the mean for the period 1892–96 For the district of Grands Carrières the mean of the last two and a half years is 47 97, instead of 69 6 as in the period 1892–96 For the district of Gouttes d Or the mean for the last two and a half years is 52 47, instead of 67 10 as in the period 1892–96 For the district of Chappelle, the mean for the last two and a half years is 48 33 instead of 58 6 as in the period 1892–96

(FROM OUR OWN CORRESPONDENT)

Etiology of Dysentery

Staff Surgeon Dr Jurgens has published in the *Deutsche Medicinische Wochenschrift* an account of bacteriological researches carried out by him during an epidemic of dysentery which broke out in a regiment in the exercise camp of Gruppe in Western Prussia The epidemic extended to 26 men who presented typical symptoms—namely, severe diarrhœa, hæmorrhage from the bowels and prostration These 26 men were admitted into the military hospitals and in addition to them there were a number of men who suffered from diarrhœa and were treated in the barracks All the patients recovered in from three to four weeks The microscopical examination proved that neither entamœba histolytica nor any other protozoon was present in the bowels Bacteria of course, were present and Dr Jurgens detected a bacillus very similar in form and culture characteristics to Kruse's dysentery b[illegible] agglutination test, [illegible] bacillus discovered [illegible] In other e[illegible]idemics [illegible] monly found in pure culture in the bowels during the first days of the disease and this bacillus is therefore believed to be the specific germ of dysentery, although the bactericidal action of the serum against the bacillus has not yet been ascertained In the recent epidemic the bacillus of Dr Jurgens was agglutinated by the blood serum of almost all the patients both during the attack and during convalescence The serum taken from patients up to the second day from the beginning of the illness had no agglutinative effect, but on the third day and afterwards it agglutinated the bacillus of Dr Jürgens but not the dysentery bacillus of Kruse. Dr Jurgens therefore infers that the etiology of dysentery is not in all cases the same, as it is not caused always by Kruse's bacilli but sometimes by another species The disease though a definite entity as to its clinical symptoms, shows marked differences from a bacteriological point of view

Professor Virchow's Library

At the last meeting of the Berlin Medical Society the librarian, Professor Ewald, announced that the widow of the late honorary president, Professor Virchow had presented the library of her deceased husband to the society on condition that it should be kept separately as a special department of the society s library By this magnificent gift the number of books of that library becomes increased by about 7000 volumes The deceased savant was a first rate bibliophile and had collected a large number of rare books, especially valuable in respect of ethnology, anthropology, and the history of medicine A detailed catalogue will be issued within the next few months

The German Emperor s Health

The announcements relative to the Emperor s health continue to be very satisfactory It will be remembered that the operation was performed on Nov 7th and a bulletin issued about ten days afterwards stated that the small wound was nearly healed and that his Majesty was allowed to speak in a whisper No further bulletins will be issued The Emperor in fine weather walks every day in the great park of Sanssouci and has already attended a musical performance in his residence Notwithstanding the favourable news published by the court journals some degree of uneasiness still haunts the public mind owing to the fact that his Majesty's convalescence is obviously less rapid than was originally anticipated Moreover, he was desirous of attending the ceremony of the oath sworn on the colours by the recruits of the Guards This ceremony takes place in the Castle square in Berlin and since his accession to the crown the Emperor has always been present and has addressed the soldiers On this occasion the ceremony was postponed several times and has now taken place in the absence of the Emperor who, however sent a representative Some time ago it was rumoured that the patient would have to winter in a southern climate and this which was at first denied by the official press, is now confirmed It is understood that the Emperor will not visit a health resort but will cruise about the Mediterranean in his yacht It is, moreover, announced that he will not start before the month of January and that this trip has been proposed, independently of the local affection of the vocal cord, only for the purpose of providing him with some relaxation and of sparing him the rigours of a Berlin winter For medical readers the fact that arrangements have been made for a long journey to commence about two months after the operation proves that the medical attendants of the Emperor have no doubt as to the absolute innocuousness of the growth which has been removed, as otherwise a further operation would become urgent within that time The public, however, are not so optimistic and are only too willing to listen to sensational gossip The surgeon in attendance on his Majesty, in addition to his physicians in ordinary, Dr Leuthold and Dr Ilberg, is Professor Moritz Schmidt of Frankfort one of the most celebrated laryngologists of Germany He was one of the late Emperor Frederick s medical advisers during his fatal illness and about six months ago he gave up his very extensive practice in Frankfort. He will stay in Berlin until the recovery of his illustrious patient is complete Professor Schmidt lately attended a meeting of the Berlin Laryngological Society, of [illegible], and the chairman, Profe[illegible] him on his successful c[illegible] that the element of interest was the patient and not the operation which was performed frequently by every laryngologist.

Death of the Princess Elisabeth of Hesse

Coincidently with the Emperor s indisposition a sad event has occurred in another reigning family of Germany The Princess Elisabeth, daughter of the Grand Duke of Hesse, whilst on a visit to the Imperial Court of Russia at Skierniwice, unexpectedly died after only a few hours' illness with the symptoms of an infectious febrile disease At a necropsy which was made by Professor Orth of Berlin (who also examined the polypus removed from the Emperor's larynx) the cause of death, notwithstanding sundry vague rumours to a different effect, was ascertained to be enteric fever.

Nov 24th

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Sanitation of Sleeping cars.

AT the recent meeting of the American Public Health Association held at the city of Washington the subject of the spread of contagious diseases through the medium of insanitary sleeping-cars was discussed with great interest by medical and lay members of that body. It was not difficult to prove that these cars are rarely thoroughly clean and wholesome and it was finally admitted by a representative of the principal sleeping or "Palace Car Company" that the blankets were washed but once a year. It has long been known that railroad companies are very negligent in regard to sleeping-cars and health authorities have frequently suspected that local outbreaks of contagious diseases were due to the transmission of their germs in filthy passenger cars, but the admission of the fact that the bedding of the most popular sleeping-cars of the country was washed but once a year was a revelation of startling significance to the entire country. If it is true that this company has so little regard for the health, comfort, and even decency of the public what can be the condition of the sleeping-cars of ordinary roads? Already the public are questioning the propriety of travelling at night when it can be avoided.

Perils of the Street.

The thoroughfares of New York have become exceedingly perilous to the pedestrian. The congestion at many points is so great that one crosses the street at the risk of one's life. This fact finds a striking illustration in the police returns of two weeks. It appears that during that period 125 accidents to pedestrians were reported as due entirely to traffic. These accidents were of such severity as to require hospital treatment and a multitude of minor injuries are excluded. The larger number of injuries are fractures. The police attribute these accidents to careless driving of carriages, trucks, and carts, the recklessness of automobile drivers, the unfitness of motor-men of trolley cars, the imprudence of bicyclists, and the large number of boy drivers. Though the law is very stringent in regard to the age of drivers of wagons it is not enforced and the result is that the streets are often crowded by every conceivable form of vehicle with reckless boy drivers who by their daring [illegible] carelessness cause the entanglement which ends in [illegible].

Dr. Lorenz's Visit to the United [illegible]

There has been much discussion of [illegible] brought Dr. Lorenz to this country and [illegible] visit upon the treatment of congenital d[illegible] hip-joint. It now appears that the child [illegible] called upon to attend was in charge of Dr. [illegible] Chicago, a very competent orthopædic surgeon. [illegible] operated on both of the dislocated limbs of th[illegible] employing Lorenz's method. The operation was succ[illegible] so far as relates to the reduction of the dislocations. Wh[illegible] however, the dressings were removed at the proper time and after an interval of a few days the right femur slipped out of place while the left remained, and still remains, in good position. It was then decided to call Dr. Lorenz to the case and accordingly he was summoned to this country. He repeated his operation on the relapsed limb and replaced it in the position which it occupied when Dr. Ridlon operated. After allowing it to remain in this position for a long period Dr. Lorenz returned and removed the dressings. The head of the femur of the relapsed limb is still in the position in which it was placed by Dr. Lorenz, though the reposition is not regarded as complete. The functions of the new joint are fairly well performed. The only criticism on the whole procedure is that Dr. Ridlon was entitled to another trial, for his success with the left hip was complete and the operation was in a measure successful on the right. A second attempt would have secured, it is believed, results equally as good as were obtained by Dr. Lorenz. But in a larger and more important sense the visit of the Austrian surgeon has accomplished excellent and far-reaching reforms in the care of crippled children throughout the entire country. Much as the discussion of Dr. Lorenz's operation by the public press was condemned, it was by that means undoubtedly that the widespread public interest in the crippled, deformed, and defective classes was excited. On every hand private institutions for the care and treatment of these unfortunates are being organised and this movement has led to similar action on the part of municipalities and lately of States.

Larceny of Antitoxin.

The city of New York, through its Board of Health, has been, and still is, distributing free of charge to the poor people antitoxin to be used as a preventive against, and cure for, diphtheria. The method of procedure is to put the remedy in small phials and to consign them to certain druggists and to authorise them, on the presentation of a proper certificate by any physician of the city, to deliver to such physician free of charge, for the use of a poor patient, one or more phials of the antitoxin, the certificate stating that this antitoxin is for the treatment of a poor patient to whom payment for the same would be a hardship. A physician obtained three phials of this antitoxin on one of these certificates and used it in a case where he knew the patient was able to pay. He was prosecuted on this charge and the court held that he was an agent of the city to administer the antitoxin to the patient for whom he obtained it, provided she was unable to pay for it, and only in that event. But it appeared that he administered the antitoxin knowing that his patient was able to pay and therefore deviated from the terms of his agency and did so to his own pecuniary gain and advantage. In other words, he appropriated the antitoxin to his own use and rendered himself amenable to the penal code which declares it to be larceny for one to appropriate to his own use public property in his control.

A Crusade against Adulterated Food

The State Dairy and Food Department of Pennsylvania has begun a crusade against adulterated foods and the results show the immense extent of the practice of tampering with human foods. In one month 200 prosecutions were commenced and $6000 were collected in fines. Upwards of 100 dairymen in the western portion of the State have recently been prosecuted and fined for putting formaldehyde in milk. Grocery firms when arraigned acknowledged selling adulterated goods, brandy, vinegar, lemon extract, &c. While it is admitted that many firms sell adulterated goods ignorantly these prosecutions are extremely useful in compelling every dealer in foods to examine carefully the [illegible] articles which he purchases and thu[illegible] the refor[illegible]

[illegible] Longevity.

The Inte[illegible] Insurance Actuaries recently [illegible]ld in New [illegible]iscussion the question of the [illegible]fe. It appears that the fact [illegible] sent pros[illegible] of life in civilised countries [illegible] establish[illegible] been ma[illegible]ened. This improvement was a[illegible]ted to th[illegible] hospitals, the advance of improveme[illegible] in the pr[illegible]edicine and surgery, and the more enlig[illegible]ened car[illegible] poor, and especially of children. It is [illegible]teresting [illegible] note the influence of widespread epidemics on th[illegible]ortality rate. Thus the small pox epidemic of 1870-74 caused an increased death-rate among all classes and ages; in the period 1880 84 the wide distribution of diphtheria, scarlet fever, and measles markedly increased the mortality among children; and the epidemic of influenza of 1891 caused a high death rate among adults. In commenting on these facts various views were expressed. One contended that the increase in longevity was not with the strong but with the weak and feeble owing to better care. Another believed that child life was now conserved as never before and hence there was a diminished average mortality. Probably these causes are only a part of a large category of efficient causes of increased longevity. The interesting fact remains that actuaries are adjusting their life risks to new conditions.

The New Harvard Medical School.

Harvard was the first of the older medical schools to take advanced ground in the improvement of medical education and the prediction was freely made that it would suffer as a consequence. It was even predicted that its classes would disappear owing to the lengthening of the term to four years and to the high standard of qualification exacted from those who entered its portals. These prophets of evil have been sorely disappointed, for instead of diminished classes they have steadily increased, money has flowed into its treasury from quite unexpected sources, and now it is about to construct an entirely new plant The administrative building will be 166 by 124 feet and will cost $535,000; the physiological laboratories will cost $431,000; the laboratories for bacteriology and pathology will cost

$390,000; histology and anatomy will have a building costing $396,000; and pharmacology and hygiene will require a structure at a cost of $346,000 When this series of buildings is completed Harvard will have no peer in equipment in this country.

Nov. 18th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The Annual Report on Charitable Aid and Hospitals: Increased Expenditure.

THE total expenditure on charitable aid in New Zealand in 1901 was £79,873, in 1902 it was £88,848, and for the year ending March 31st last it amounted to £93,158. The amount distributed on outdoor relief for the year ending March 31st, 1902, was £38,934 and for the year ending March 31st last it amounted to £43,421. In the four large towns the expenditure on outdoor relief alone was as follows:—Auckland Charitable Aid Board, £4923; Christchurch Charitable Aid Board, £7356; Dunedin Benevolent Trust, £6048; and Wellington Benevolent Trust, £4681. It will be seen that there is a considerable increase in outdoor relief all along the line. The Wellington Benevolent Trust has increased its outdoor relief during the past year by £1305 Dr. D. McGregor, the Inspector-General of Hospitals, remarks: "It is a fact accepted by all careful students of social science that pauperism grows by giving too freely and badly administered outdoor relief merely intensifies the evil its administrators desire to mitigate." The Benevolent Institution at Caversham, the report says, is still over full and understaffed. Many years ago, before the new buildings began to be erected, the Inspector-General did his best to impress upon the trustees how unwise it was to erect new buildings on so small a piece of ground, amounting to not more than eight and a half acres. A piece of good land must be obtained somewhere in the Taieri and a building must be erected to be worked in connexion with the central institution. The item "wines and spirits" for Auckland Hospital amounted to £314 for the year, for Christchurch Hospital to £61, for Dunedin Hospital to £186, and for Wellington Hospital to £173 "The Nurses' Registration Act," the Inspector General observes, "has now been in force for a year and a half and is working smoothly. There are 320 names of nurses on the register. There were 29 nurses entered as candidates for the examination held in May last and 27 of these passed and are duly registered. Such an Act is necessary owing to the advance of scientific surgery and the progress of medical knowledge. It protects medical men and also the public from the increased number of unqualified women who pose as nurses and who too often prove a real danger in critical illness and in operations. It is interesting to note that within the last few months five of the American States—North Carolina, New York, Illinois, Virginia, and New Jersey—have followed the lead of this colony and passed Acts for the State registration of duly qualified nurses. The Nurses' Registration Act of New Zealand uses no compulsion except that of enlightened self-interest on the part of the nurses themselves, and it is daily becoming more apparent that by the silent pressure of this law the nursing profession of New Zealand will be effectively organised. The whole working of it has been entrusted to Mrs Grace Neill and the tact and skill by which she has carried on all the arrangements, often complicated and difficult as regards the examinations, have earned my highest appreciation and gratitude These biennial examinations have been moulded on the system of the New Zealand University. The examiners have no knowledge of the name or hospital of the candidates whose papers they are examining and great care has been taken in electing as examiners medical men who have had especial knowledge of the training of nurses. The examination in the practical work of each nurse is undertaken by a medical man and a registered nurse conjointly."

Lunacy Report: Increase of Insane Patients; Overcrowding of the Asylums; a Plea for the Attendants.

The lunacy report, laid on the table of the House of Representatives, shows that on Dec. 31st last there were 2848 registered insane persons in the colony, being an increase of 75 over the previous year. The proportion of the total insane to the total population was, exclusive of Maoris, 3·50 per 1000 or 1 in 286; inclusive of Maoris, 3·35 per 1000, or 1 in 299. The admissions during the year for the first time totalled 440 and the re-admissions 104. The percentage of deaths on the average number resident during the year was 6·28, as compared with 6·41 for the previous year. The percentage of deaths on admissions was 32·17 and the percentage of recoveries on admissions 43·01, as compared with 41·17 for the previous year. The average cost per patient for the year was £29 6*s* 10*d*., as against £28 16*s* 11½*d* for 1901, the increase being mainly due to the rise in the price of meat and flour. Wellington (£34 11*s*. 7¼*d* per patient) was the most costly asylum and Auckland (£24 7*s*. 0¼*d*) was the cheapest. Dr. McGregor reports that at Auckland there are 551 patients but only floor space for 493 The asylum is therefore overcrowded to the extent of 58 patients. The following figures show the extent of overcrowding at our asylums: Auckland, 58; Christchurch, 96; Seacliffe, 61; Nelson, 4; Porirua, 10; and Wellington, 47; total 276. There is room at Hokitika for 24. The Inspector-General observes that one thing in which we are helplessly astern of the whole British empire is the overcrowding of our asylums, a fact which goes far to nullify, so far as the rational treatment of patients is concerned, all our other advantages. He has some hopes, however, that the Government may soon take steps to provide intermediate accommodation for uncertifiable cases near Christchurch. In view of the universal change in the condition of the labour market Dr. McGregor thinks it necessary to raise the wages of the asylum attendants. Artisan and charge attendants ought to receive an increase of 25 per cent. and the ordinary attendants an increase of 20 per cent. It will be necessary also, in his opinion, to increase the salaries of assistant medical officers to £300 instead of £250, rising to £350 after five years' service, for it has been found impossible to get suitable applicants at the lower figure. It is again recommended that Parliament should agree to give medical superintendents 12 months' holiday on full pay every sixth year. The great strain which they have had to bear has all but broken down every one of them. From the statistics comparatively little is to be learned. Medical experts will probably agree that they are very wide of what such statistics should be. To classify a man as a "labourer" or a "farmer" in such a colony as ours or to give "domestic duties" as an index to a woman's past history is rather farcical Practically nothing is being done in this direction, which is admittedly of supreme importance in the study of the question The asylum medical officers, overworked and under-staffed, cannot possibly be expected to give the time that would be required to make even an intelligible statistical return. Fuller returns on this question would meet with grateful recognition from all students and experts.

Wanganui, Oct. 12th.

Obituary.

SIR ROBERT MARTIN CRAVEN, KT., F.R.C.S. ENG. AND EDIN., J.P.

ON Nov. 15th there passed away at the ripe age of 80 years Robert Martin Craven, for many years a well-known practitioner of Hull. He came of a medical family, for his father, Robert Craven, and his grandfather, Robert Martin Craven, were both surgeons practising in Hull Robert Martin Craven the second, the subject of this memoir, was born in Hull in 1824 and was educated at Kingston College, Hull. He commenced his professional studies at the Hull General Infirmary and continued them at St Bartholomew's Hospital, London, and at the hospitals of Paris. In 1846 he was admitted a Member of the Royal College of Surgeons of England and in 1847 he became a Licentiate of the Society of Apothecaries, London. In 1849 he commenced the practice of his profession in partnership with his father and in 1852 was elected an honorary surgeon to the Hull General Infirmary, a post which he resigned in 1892, being then made consulting surgeon. In 1886 a ward had been named the Craven Ward in memory of services rendered by three generations of Cravens. From 1850 to its dissolution in 1870 he was lecturer in anatomy at, and secretary to, the Hull Medical School. In 1879 he was elected a Fellow of the

Royal College of Surgeons of Edinburgh, receiving the same honour from the Royal College of Surgeons of England in 1889. He was twice chosen President of the local branch of the British Medical Association and was also from time to time President of the various literary and scientific societies of Hull. In 1877 he was made a justice of the peace and in 1878 he was chosen as sheriff of Hull, being as a final honour knighted in 1896. With regard to matters outside a purely professional sphere Sir Robert Martin Craven was a Conservative in politics and a Churchman. From 1885, the year of its foundation, he was President of the Central Hull Conservative Council—a post which he held until his death. He was twice married, his second wife, a daughter of Robert Welsh, W.S., of Edinburgh, being a descendant of John Knox and a cousin of Jane Welsh Carlyle. Throughout his long life Craven was an earnest worker and was always held in great esteem even by those who differed from him. More especially was he honoured by his professional brethren, not only on account of the good work which he did, but also for the standard of strict professional integrity which he always held aloft. His body was buried in the General Cemetery, Hull, on Nov. 18th, the previous portion of the burial service having been said at St. Mary's Church.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Cézilly who founded the well-known French medical journal *Le Concours Médical.*—Dr. Vladimir Brodowski, formerly professor of anatomy in Warsaw.—Dr. Adam Gliszczynski, formerly professor of midwifery and gynæcology in Warsaw.—Dr. Barsis, formerly editor of the *Wiener Medicinische Presse*, at the age of 39 years, at Meran.—Dr. Otto Nasse, who was professor of pharmacology and physiological chemistry in the University of Rostock from 1880 to 1899. He wrote the portions of "Hermann's Physiology" dealing with chemistry and the metabolic changes in muscular tissue.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, NOV. 24TH.

THE seventy-eighth session of the General Council of Medical Education and Registration was opened to-day in the offices, Oxford-street, London. The PRESIDENT, Sir WILLIAM TURNER, K.C.B., Principal of the University of Edinburgh, occupied the chair.

Introduction of Sir John William Moore, M.D.

Dr. LITTLE formally introduced to the President and to the Council Sir John William Moore who has been appointed to succeed Dr. Lombe Atthill in the representation of the Royal College of Physicians of Ireland.

President's Address.

The PRESIDENT then delivered his inaugural address.

[After referring sympathetically to the resignation of Dr. Lombe Atthill and to the death of Sir George Duffey he said:—]

I may remind the Council that the inspection of the final examinations of the Scottish universities, which in the customary course should have been undertaken during this year, was owing to Sir George Duffey's illness deferred until 1904. In order that this duty may be discharged at the respective periods of examination it will be necessary either to appoint an inspector before the Council separates or perhaps perferably to authorise the Executive Committee to do so at its meeting in February. In connexion with the series of inspections I should state that the report on the inspection of the final examination of the Apothecaries' Society of London held in January last, at which Dr. Bruce was associated as visitor with our inspector, has been completed by Dr. Bruce with the aid of the memoranda prepared by Sir George Duffey. I have also to intimate that Dr. W. P. Herringham, who has acted for three years as the Council's inspector specially appointed to report on the examinations held at the Apothecaries' Hall, Dublin, has resigned his office. The Council will no doubt wish to recognise that his duties have been discharged with judgment and discretion. In view of the character of recent reports and the improvements which have been effected in the examinations the Council may perhaps think it no longer to be required that each examination should continue to be inspected and as the Council has power under the Act to prescribe the duties to be discharged by the assistant examiners appointed by the Council that a visitation and report from time to time by a special inspector may be all that is now necessary.

I have received a communication from the secretary of the Dublin Apothecaries' Hall in which the request is made that it should be relieved of the burden entailed by the travelling expenses of the assistant examiners in surgery appointed by the Council. As the presence of these examiners is necessary in order to enable the Dublin Apothecaries' Hall to conduct a qualifying examination for the diploma, and as the statute requires that such remuneration as the Council determines is to be paid by the medical corporation at whose examinations they take part, it seems clear that the Apothecaries' Hall should continue to bear the charges attendant on the presence of the examiners. Since my address was in print the Society of Apothecaries Dublin has intimated its intention to resume on Jan. 1 1904, its preliminary examination in arts

[The President then pointed out that under the division Victoria University the new University of Liverpool has become entitled to hold qualifying medical examinations to be represented on the General Medical Council. understood that the appointment of Mr. Young, the prese representative of Victoria University, remained unaffect and that he holds his seat on the Council until resignati or the expiration of the term for which he was origina appointed. The President continued:—]

No charter has yet been granted to establish a univers in Yorkshire, although it is not unlikely that one may granted in the immediate future.

At the July meeting of the Council I was requeste to forward to the Royal Colleges of Physicians a Surgeons in London the reports of the Council's Educ tion and Examination Committees, together with th Council's resolutions thereupon, to call the attention of th Colleges to the unsatisfactory condition of the courses study and examination in chemistry, physics, and biolog disclosed in these reports, and to urge that in the interes of medical education immediate steps should be taken remedy the defects referred to. I was further authorised appoint a committee to join with me in conferring wi representatives of the Royal Colleges should it appear that conference on the questions raised was desired. Accordingl I communicated with the two Colleges and was informed due time that the Council of the Royal College of Surgeon had had under consideration my letter and the accompanyin documents and had appointed delegates to confer with del gates of the Royal College of Physicians respecting the pr posed conference. In the early part of this month a speci committee consisting of the two groups of delegates m and considered the questions raised in my letter. This com mittee has now reported to the Colleges and it recommend that the General Medical Council be thanked for the expre sion of its opinions respecting the courses of study and th examinations in chemistry, physics, and biology, and tha these opinions should receive the respectful attention of th two Royal Colleges. Further, the committee recommend that the Royal Colleges should express regret that they a unable to accept the invitation of the President of th General Medical Council to appoint representatives to mee the committee of the Council in regard to the question o medical education and examination in chemistry, physi and biology, which has been raised in the reports of th Council's Education and Examination Committees. An officia communication has now been received from each of the tw Colleges reporting the adoption of the recommendations o the committee of delegates as the reply of the Colleges to m communication.

In my address from the chair in May last I referred to th question of reciprocity between the United Kingdom and Canada in regard to the registration of their respective medical qualifications and I made a suggestion which in the event of one of the provincial legislatures declining to avail itself of the Canadian Medical Act, 1902, would, if adopted, enable the other provinces to establish reciprocal relations with the United Kingdom under Part II. of the Medical Act 1886. The Provincial Medical Board of Nova Scotia has sent me a resolution passed at the annual meeting in which it endorsed that suggestion. As requested by the Council I communicated with both the Privy Council and the Colonial Office to ascertain if the suggestion was likely to be favourably regarded by the Government of the Dominion of Canada or by the medical authorities who have supported the Canada Medical Act, 1902 In reply I have been informed that the Canada Medical Act was introduced and carried through the Dominion Parliament by a private member, no legislation having been initiated by the Government of Canada, and that the Ministers are not aware if an amendment of the Act is in contemplation during the present session.

In accordance with the request of the Council I asked the attention of the Lord President of the Privy Council to a Pharmacy Bill then before Parliament, in which the rights of the medical profession as safeguarded by existing Pharmacy Acts appeared to be encroached upon. In reply I am assured that the Council of the Pharmaceutical Society has no intention of interfering with medical practice and that it has prepared a clause for insertion in a future Bill to insure that it shall not interfere with or abrogate any of the rights reserved in the Pharmacy Acts, 1868 and 1869. A communication to the same effect has been received directly from the secretary to the Pharmaceutical Society.

A letter has been addressed to us by the Consultative Committee of the Board of Education with regard to the institution of a general system of leaving examinations for secondary schools in England, which could be accepted in lieu of the preliminary examinations now required for admission to the various professional bodies. The Council is invited to send one or two representatives to a conference with the Consultative Committee to be held on Friday, Dec. 4th. Those of us who live in Scotland are familiar with the beneficial effect which the introduction some years ago of a national system of leaving examinations and certificates has had in raising the standard of education in the secondary schools in that division of the United Kingdom. It is very satisfactory to hear that it is proposed to introduce in England a similar system and it must be gratifying to this Council to be asked to take a part in so important a conference. It is to be hoped that the conclusions arrived at and the subsequent action of the Board of Education thereupon will result in the establishment in England of a system of leaving examinations which, so far as this Council is concerned, will simplify the much discussed question of the preliminary education of students of medicine. For in questions which do not directly fall within its own competency the Council cannot stand outside a well considered national scheme of education and examination intended to qualify for admission to the various professions.

[The President then referred to the reports of the Examination Committee and Education Committee to be placed before the Council and continued :—]

The Council having adopted at its meeting in May a memorandum which I then submitted to it on its financial position and on the inadequacy of its income, I have communicated the memorandum officially to the Lord President of the Privy Council and have requested that consideration would be given to the subject, with a view to the financial difficulties being removed, either in the manner suggested in the memorandum or in some other way. I have reason to know that the question is now being carefully considered.

A communication has been sent by the Home Secretary inclosing a copy of a letter which he had received from the coroner of the Pickering Division of the North Riding of Yorkshire with regard to inquests in cases where the deceased has been attended by a person who is not a registered medical practitioner. The attention of the Council has on various occasions been called by coroners and other official persons to this matter and it has been made the subject of repeated representations by us to the various Government authorities, but up to this time no remedial legislation has been provided. Subject to the approval of the Council I propose to make a further representation to the Local Government Board on this question A number of registered medical practitioners in Glasgow have presented to the Lord President of the Privy Council a petition respecting the action of the Pharmaceutical Society of Great Britain and of the General Medical Council with reference to the sale of scheduled poisons by unqualified assistants This petition has been transmitted by the Lord President for our information.

[The President concluded by expressing a hope that the Council would be able to complete its work at the beginning of next week.]

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the Council thanked Sir William Turner for his address.

Service Examinations.

Mr. ALLEN, the Chief Registrar, presented to the Council a series of tables showing the results of certain examinations for commissions on the medical staffs of the Royal Navy, His Majesty's Army, and the Indian Medical Service.

The tables were received and the thanks of the Council were accorded to the Government officials who supplied the information.

Mr. G. BROWN intimated that he would place upon the business paper a notice with regard to the number of rejections disclosed in the tables in order that the subject might be discussed at a subsequent stage by the Council.

In Camerâ.

The Council sat for a while in private but no announcement was made as to the subjects under discussion or as to the results.

Leaving Examinations for Secondary Schools.

The following communication was received and entered on the minutes :—

Board of Education, South Kensington,
London, S.W., Oct. 27th, 1903.

CONSULTATIVE COMMITTEE.

[illegible]

confer:—

Whether it is desirable and feasible to institute for secondary schools in this country (excluding for the present Wales and Monmouth) a general system of leaving examinations of such a nature as to be acceptable in lieu of the preliminary examinations now required

[illegible]

discussion.

[illegible]

invitations.

They will be ready carefully to consider any scheme put before them, with any accompanying ob

[illegible]

ervant,
A. R. GUEST,
Secretary to the Consultative Committee.

The Registrar,
General Council of Medical Education and Registration.

Dr. PAYNE moved—

[illegible]

He mentioned that Dr. Windle was a member of the Consultative Committee.

The moti[illegible] seconded by Dr. NORMAN MOORE and was agreed to.

The Cour

Wednesday, Nov. 25th.

The Council resumed to-day, Sir William Turner, the President, being in the chair.

The Case of Dr. William George Niall.

Consideration was resumed of the case, partly heard on May 27th and 28th last, of Dr. William George Niall, registered as of Kinkora, Dabdune-crescent, Guildford, M.D, Mast. Surg. 1886, R. Univ. Irel., who had been summoned to answer a charge formulated by the Council's solicitor (Mr. Winterbotham).

The President ordered parties to be called and said: I would remind the Council that this case was before us on the 27th of May last, when it was decided that it should be heard *in camerâ*. The Council will proceed with it *in camerâ*, and strangers, therefore, will withdraw.

The rest of the sitting was occupied with the case. On the re-admission of parties and the public, just on the usual hour of rising for the day,

The President, addressing Dr. Niall, said: The Council has deliberated on your case and I have to inform you that the facts alleged against you in the notice of inquiry have not been proved to the satisfaction of the Council. That completes the case.

The Council adjourned.

Medical News.

Royal College of Surgeons of England.—The following gentlemen having passed the necessary examination have been admitted as Members:—

George Basil Doyne Adams, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Robert Grenville Anderson, Guy's Hospital; Edward Guy Anthonisz, St. Mary's Hospital; John Gerald Atkinson, St. Bartholomew's Hospital; Seymour Gilbert Barling, Birmingham University; Charlie Barlow, L.R.C.P. Lond., and Thomas Edward Blunt, London Hospital; Gerald Eade Bellamy and Bertram Raleigh Bickford, Charing Cross Hospital; Percy Claude Vincent Bent and Sidney Clement Bowle, L.D.S. Eng., Guy's Hospital; Hugh Wood Bethell, B.A. Camb., Cambridge University and Guy's Hospital; Amelius Cyril Birt, St. Thomas's Hospital; Henry Jameson Cardew, B.A. Camb., Cambridge University and S[illegible] Fergusson Titton Carr-Harris, M.D. Canada, [illegible] Canada, and University College Hospi[illegible] King's College Hospital; David Brynm[illegible] College, Cardiff, and University College Hospital; Harold Clapham, St. Mary's Hospital; Frederick Cock, Charing Cross Hospital; James Douglas Cooke, Melbourne University and London Hospital; William Lawrence Cripps, Cambridge Universit[illegible] Hospital; William Allen Cumming, M[illegible] University, Montreal, and St. Mary's [illegible] Davies, University College, Cardiff, and Charing Cross Hospital; Mervyn Eager, King's College Hospital; Leonard Erasmus Ellis, L.S.A. Lond., St. George's Hospital; Herman Falk, B.A. Camb., Cambridge University and St. Thomas's Hospital; George Ernest Oswald Fenwick, University of New Zealand and University College Hospital; Arthur Edwin Fiddian, [illegible] Cardiff, and St. Mary's Hospital; Walter [illegible] Mary's Hospital; Henry Richmond Fisher, [illegible] University and London Hospital; Leona[illegible] M.A. Camb., L.D.S. Eng., Cambridge Univ[illegible] Hospital; Frank Medwin Gardner-Medwin, B.A. Camb., St. Bartholomew's Hospital and Cambridge University; Wilfrid Garton, St. George's and Westminster Hospitals; Owen Binns Gauntlett and Harry Morgan Gilmour, St. Thomas's Hospital; Francis Willoughby Goyder [illegible] University and St. Mary's Hospital; [illegible] College and Royal Infirmary Manc[illegible] M.B. Toronto, Toronto University; Arthur Hallowes, St. Bartholomew's Hospital; William Thompson Hamilton, M.B. Toronto, University College, Toronto; Sydney Lawrence Harke, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Bernard Higham, St. Thomas's Hospital; Robert B. Dennis Hird, Birmingham University; Geoffrey Gratrix Hirst, B.A. Camb., Cambridge University and Middlesex Hospital; Basil Hood, Charing Cross Hospital; William Stanley Hughes, St. Mary's Hospital; John James, King's College Hospital; William Johnson and Herbert Stanley Jones, Guy's Hospital; James Douglas Judson, Owens College and Royal Infirmary, Manchester; John Newport Kilner, St. Mary's Hospital; Stephen March Lawrence, St Bartholomew's Hospital; William Collins Lewis, Guy's Hospital; Travis Clay Lucas, B.A. Camb., Cambridge University and Guy's Hospital; Evelyn John Hensler Luxmoor, St. Mary's Hospital; William Cameron Macauley, B.A. Lond., Middlesex Hospital; Charles Markus, M.D. Germany, Freiburg and University College Hospital; James Ernest Martin and Roy Charles Merryweather, University College Hospital; Arthur Martineau, B.A. Camb., Cambridge University and London Hospital; Cecil Francis Nicholas, St. Ba[illegible]w's Hospital; William Wilson Nock, Birmingham Univ[illegible] William Boyle Norcott, Queen's College, Cork; Robert Geor[illegible]hwanger, M.A. Camb., Cambridge and St George's Hospita[illegible]derick Pitcairn Nunneley, B.A. Oxon., Oxford and St. George's Hospital; Basil Hewitt Pain, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Russell Edwards Palmer, George Ernest Peacholl, and Ernest Aubrey Price, St. Mary's Hospital; Leonard Gregory Parsons, Birmingham University; Percy Clift Peace, University College and General Infirmary, Sheffield; Charles T[illegible] and Charles Alfred Whiting P[illegible] and St. Bartholomew's Hospit[illegible] Thomas Edward Regan, Owe[illegible] chester; Donald Murray [illegible] Thomas's Hospital; John Bar[illegible], St. Mary's Hospital; Job Latham Rushton, King's College Hospital; Henry Thomas Samue[illegible] University College, Cardiff, and St. Bartholomew's Hospital; Harold [illegible]liff, M.A. Oxon., Oxford University and St. [illegible] Walter Henderson Scott, Alec Job Lincoln [illegible] Ernest Taylor, St. Bartholomew's Hospital [illegible] Sidgwick, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Charles Joseph Singer, B.A. Oxon., St. Mary's Hospital; William Gordon Taylo[illegible] M.A. Ab[illegible] College [illegible] Universi[illegible] Vaughan [illegible] Alexander Moxon Webber, and Richard Willan, Guy's Hospital; George Delaval Walsh, London Hospital; Solomon James Weinberg, Owens College and Royal Infirmary, Manchester; Hugh Wheelwright, St. Thomas's Hospital; Edward How White, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Robert Glover Wills, B.A. Camb., Cambridge University and University College and Royal Infirmary, Liverpool; Oswald Charles Withrow, M.B. Toronto, Toronto University and Middlesex Hospital; Alexander Frederick Richmond Wollaston, B.A. Camb., Cambridge University and London Hospital; and Harold William Wilson, Lauriston Leonard Winterbotham, and Walter Perceval Yetts, St. Bartholomew's Hospital.

Society of Apothecaries of London.—At examinations held in November the following candidates passed in the subjects indicated:—

Surgery.—G. Nunn (Sections I. and II.), Guy's Hospital; P. J. Pagonis, Athens; P. A. Pettavel, Lausanne; C. H. Pring (Section II.), Westminster Hospital; and L. S. Shoosmith (Sections I. and II.), St. Mary's Hospital

Medicine.—S. Bentley (Section II.), Sheffield; C. C. Bernard (Section I.), Royal Free Hospital; P. Elias (Section I. and II.), Amsterdam; F. Hansen (Section II.), Copenhagen; W. B. Harris (Sections I. and II.), St. Mary's Hospital; P. S. Klots, Leyden; W. S. Lewis (Section II.), Birmingham; and C. H. Pring (Section II.), Westminster Hospital.

Forensic Medicine.—C. C. Bernard, Royal Free Hospital; F. M. Boclet and G. C. M. Davies, Charing Cross Hospital; P. Elias, Amsterdam; J. H. Harrison, Sheffield; H. M. Jones, Royal Free Hospital; P. S. Klots, Leyden; and T. R. Waltenberg, Manchester.

Midwifery.—L. F. Cope, St. George's Hospital; G. C. M. Davies, Charing Cross Hospital; P. Elias, Amsterdam; A. T. Greenhill, St. Bartholomew's Hospital; R. J. S. Verity; Charing Cross Hospital; and A. Whitby, Dublin.

The diploma of the Society was grantec [illegible] candidates, entitling them to practise medicine, surger[illegible] F. M. Boclet, F. Hansen, W. B. Harris, P. [illegible] Pettavel, C. H. Pring, and L. S. Shoosmith.

Royal College of Surgeons in Ireland—Fellowship Examination.—The following candidates have passed the Primary part of the Fellowship examination:—

P. F. Foran, Dublin; Miss C. E. O'Meara, Dublin; H. J. Perry, Cork; and H. Stevenson, Belfast.

Trinity College, Dublin.—At the Previous Medical Examination at Michaelmas term the following gentlemen passed in the subjects indicated:—

Anatomy and Institutes of Medicine—Alfred C. Elliott, Francis J. Usher, Daniel M. Corbett, Hercules J. Knox, Michael P. Leahy, and Ernest C. Phelan.

Physics and Chemistry.—Edmond H. Sheehan, Johann A. L. Hahn, Thomas P. Dowley, James G. M. Moloney, Frederick R. Sayers, William H. Sutcliffe, Gordon A. Jackson, John W. Lane, Charles H. O'Rorke, and Henry de C. Dillon.

Botany and Zoology—Thomas H. Gibbon, Frederick C. Anderson, Horace F. Blood, Samuel F. A. Charles, Henry D. Woodroffe, and Thomas J. T. Wilmot.

Bradford Sanatorium for Pauper Consumptives.—A sanatorium for the treatment of consumptives in the Bradford Union was opened at Eastby, near Skipton, on Nov. 3rd by Sir Francis S. Powell, Bart., M P; it was commenced in October, 1902. The area of the site is six and a half acres. So far only one pavilion, a wooden structure 165 yards in length, has been provided. The patients' rooms, which number ten, are all on the ground floor. The nurses' quarters are upstairs and the bathrooms, lavatories, and other conveniences are at the rear of the pavilion. All corners are rounded to prevent the accumulation of dust and the staircase is open both at the back and the sides. The administrative block is of stone and is a one-storeyed building. Water has been secured from a bore-hole 200 feet deep from which it is pumped by means of a small windmill. An electric plant is provided and the buildings are heated by hot water. The adjoining woods have been placed at the disposal of the patients by the Duke of Devonshire. Mr. F. H. Bentham, chairman of the Bradford board of guardians, said that the estimated cost of the scheme was £10,000. The scheme provided for 52 patients. At the present time they were ready to treat 21 but it was anticipated that a second pavilion would be erected shortly. The cost would probably work out at £200 per bed as against £600 in other sanatoriums in various parts of the country. There was no reason why the patients should be confined solely to the pauper class and he hoped other sufferers would eventually find succour there.

PRESENTATION TO A MEDICAL MAN.—Mr. R. A. D. Daniel, M D *Durh.*, L.R C P., L.R C.S. *Edin.*, L.F.P.S. Glasg., who until recently had an extensive practice in the Hammersmith and Chiswick districts, was on Nov. 23rd the recipient of a testimonial from a number of his old patients in the shape of a silver Georgian tea and coffee service, a hot-water jug to match, and a cheque for 35 guineas to purchase any personal present he might desire.

UNIVERSITY OF OXFORD.—In a Convocation held on Nov. 17th the names of the following persons who had been duly nominated to serve as examiners in the examinations for the degree of B M. were submitted to the house and approved (*nemine contradicente*):—First examination: Francis Gotch, M A, D Sc., F.R S, Fellow of Magdalen College, Waynflete professor of physiology (in human physiology); second examination: Gustave I. Schorstein, M.A, B M., Christ Church, F.R.C.P. (in medicine). The following are the dates announced for the examinations for the scholarships in natural science: Dec. 8th, Balliol College, Christ Church, and Trinity College; Jan. 12th, 1904, Jesus College; Jan. 19th, Lincoln College; March 15th Keble College; March 22nd, Magdalen College; and April 19th, Merton College, New College, and Corpus Christi College.

ST. MARY'S HOSPITAL.—The retirement of Sir Anderson Critchett and Mr. Malcolm A. Morris from the hospital staff of St. Mary's Hospital after 20 years of service was signalised on Nov. 20th by the presentation of two silver candelabra to Sir Anderson Critchett and 145 volumes of the *Annual Register* to Mr. Morris The ceremony took place in the board room of the hospital and Sir William H. Broadbent, Bart., K.C.V.O., was the spokesman for the subscribers to the testimonial. The friends of the two retiring members of the staff assembled in full force and loudly applauded the eulogistic sentiments uttered by Sir William Broadbent He said that they had gathered there to do honour to Sir Anderson Critchett and Mr. Morris and to offer them on the part of old and present St Mary's men some small testimony of the esteem and regard in which they were held. Continuing, Sir William Broadbent said that the occasion marked the severance of the active connexion of the two retiring gentlemen with the hospital and that entailed a great loss to them and to the institution. After discussing the merits and demerits of the regulation that obliged members of the staff to retire after 20 years' active service, Sir William Broadbent proceeded to deliver a panegyric on the services rendered to the hospital by Sir Anderson Critchett and an eloquent appreciation of Sir Anderson Critchett's work in ophthalmology was greeted with hearty applause. In regard to Mr. Morris Sir William Broadbent particularly emphasised his enthusiasm and observed that all would agree that Mr. Morris's restless energy was his great characteristic He praised the book on "Skin Diseases" that Mr. Morris had written and detailed the benefits which the public had derived from the influence of the National Association for the Prevention of Consumption and other Forms of Tuberculosis which Mr. Morris was so largely instrumental in founding. Sir [illegible] monial, said th[illegible] father of the [illegible] Hospital, beca[illegible] existed as a w[illegible] theless he could at any rate claim that he was its foster father. He traced the growth of his department from an average attendance of ten or 12 to the large number of patients attending at the present time and described how he had had a large share in the ophthalmological education of some 40 house surgeons Mr. Morris contented himself with a short but effective farewell speech. He spoke in a feeling manner of how hard it was after 20 years' friendship suddenly to part with valued friends and colleagues. He looked on the occasion as a tribute of sympathy offered to him in alleviation of the unpleasant ordeal of retiring from active service on the staff while still in full possession of his faculties Mr. Edmund Owen, in a neat and witty speech of a few minutes' duration, in which he referred to open graves, lamentations, rue, and rosemary, proposed a vote of thanks to Sir William Broadbent for presiding and shortly afterwards the meeting came to an end.

THE NATIONAL DENTAL HOSPITAL.—The £40 entrance exhibition for this session has been won by Mr. G. W. Geekie, B A. *Oxon.*, and the one for £20 has been divided between Mr. Walter Rose of Liverpool and Mr. C. H. Taylor of Hornsey, N.

LITERARY INTELLIGENCE.—Owing to the greater portion of the 1904 edition of *Who's Who* having been destroyed by fire at the binders, subscribers may in some instances experience delay in getting their copies. The reprinting is being rapidly pushed forward.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The working men of the Keyham and Devonport dockyard have handed to the treasurer of the Royal Albert Hospital, Devonport, the sum of £340 which has been collected by them during the past 12 months for the funds of that institution.

ATTEMPTED MURDER OF A MEDICAL MAN.—Mr. George Whittenbury White, junior resident medical officer at the Union Infirmary, Fir Vale, Sheffield, has been the victim of an attack by a ruffian named Edward North. The man complained of pains in the back and while Mr. White was examining him drew from his sleeve an open clasp knife and lunged with it towards Mr. White's head. Mr. White dodged and escaped the first blow but the second blow caught him in the ear. North was at once felled and secured by the attendants. Revenge appears to have been the man's motive for the attack, as he is reported to have said that he hated all doctors for what he went through at Wakefield Gaol, when he got the "cat" and the medical officer stood by and allowed it. He had only recently been released from that gaol where he had served a sentence for burglary. Mr. J H. Bellamy, the senior resident medical officer, describes Mr White's injury as a punctured wound about an inch long and three quarters of an inch deep extending backwards from the lower border of the left external auditory meatus towards the mastoid process. It required suturing and is now healing well and neither permanent ill-effects nor prolonged absence from work are anticipated. Mr. White is to be sincerely congratulated upon the fortunate issue of a very determined attempt at murder.

DINNER TO PROFESSOR HOWARD MARSH.—On Nov. 17th a complimentary dinner was given at the University Arms Hotel, Cambridge, to Mr. Howard Marsh on his appointment as professor of surgery at the University of Cambridge by old students of St. Bartholomew's Hospital residing in Cambridge and the vicinity. Dr. P. W. Latham of Cambridge occupied the chair and those present included Sir William S. Church, Bart., Mr. A. Willett, Dr. A. Hill (Master of Downing College), Dr D. MacAlister, Dr. L. Humphry, Dr E. Lloyd Jones, Dr. H. K. Anderson of Great Shelford, Mr. T. W. Burn, Dr. W. Malden, Mr. J. Giles of Caxton, Mr. E. F. Bindloss of Swavesey, Dr. R. W. Michell, Dr. H. Skelding of Bedford, and Mr. F. E. Apthorpe Webb. After the usual Royal toasts the Chairman in well chosen words proposed the health of "Our Guest." Alluding to the brilliant career of Professor Marsh he said that the appointment was an honour no less to the hospital than to Professor Marsh. He thought it very gratifying that among the colleagues and pupils of Professor Marsh who had met to do him honour they had the presence of the Presidents of the Royal College of Physicians of London and of the Royal Medical and Chirurgical Society, together with the Master of Downing College. Professor Marsh, on rising to reply, was accorded a very hearty reception. He expressed his gratitude to those present for the compliment they had paid him and said that he would endeavour to keep up the traditions both of his school and of the University. Dr. Hill then proposed "Success to Our Sch[illegible] that the connexion between St. [illegible] University of Cambridge still [illegible] rch, in responding, said that [illegible] e to be present to show the regard and esteem in which Professor Marsh was held by all St. Bartholomew's men. Mr. Willett also replied and alluded to the changes which had taken place with regard to the work of the hospital during Professor Marsh's connexion with the school. Mr. Bindloss proposed "The Chairman." Dr. Latham, in reply, reminded those present that when the late Sir G. Humphry was a candidate for the post of house surgeon to Addenbrooke's Hospital two other St. Bartholomew's men also applied—viz, Luther Holden and Holmes Coote, both of whom afterwards became surgeons to the hospital. A vote of thanks to the honorary secretary terminated a successful and enjoyable evening.

BOOKS, ETC., RECEIVED.

ADAMS BROS., 27, Old Jewry, E.C.

The Diseases of the Mouth and Teeth. By Lloyd T. Levan, L.D.S., R.C.S., late Assistant House Surgeon, National Dental Hospital. Part I. The Diseases of the Antrum (Maxillary Sinus). Price not stated.

BOWEN DAVIES.—On Nov. 21st, at Pendinas, St. Asaph, N. Wales, the wife of W. L. Bowen Davies, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

HUDSON.—On Nov. 19th, at Vine House, Cobham, Surrey, the wife of Arthur B. Hudson, M.R.C.S., L.R.C.P. Lond., of a son.

TYSON.—On Nov. 18th, at Folkestone, the wife of W. J. Tyson, M.D., F.R.C.P., of a daughter.

MARRIAGES.

MATHEW—SAUNDERS.—On Oct. 29th, at St. James', Sea Point, by the Very Revd. the Dean of Cape Town, assisted by the Revd. J Deacon, Mabel, younger daughter of John Saunders, Esq., of Sea Cliffe Sea Point, to G. Porter Mathew, M.A., M.D. Cantab., of Port Elizabeth, Cape Colony.

TURNER—MAHOMED.—On Oct. 23rd, at Cape Town, George Albert Turner, M.B., M.O.H. for Kimberley, to Nellie, eldest daughter of the late F. A. Mahomed, M.B., F.R.C.P., and of Mrs. Mahomed.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE OD CHEM CO

WE have upon previous occasions had to animadvert upon the business methods of this firm but portions of its latest "literature" which is now being distributed broadcast to the members of the medical profession exceed in filth anything to be found in the pages of Casanova or of other 'curious' works As usual the Od Chem Co is puffing its preparation sanmetto which we are quite willing to allow may *be useful in certain cases The company has* apparently got some medical men to write articles about the treatment of sterility and on Normal Reciprocity and How it is Obtained These articles are reprinted in the pamphlet before us not so much with the desire of instructing the medical profession as of calling attention to the virtues of sanmetto We are not going to quote the passages to which we refer, suffice it to say that they repeat in the plainest and most bald language the advice which van Swieten gave decorously veiled in Latin to the childless Maria Theresa The advice has, we believe, been found by competent medical authorities to be sound but our contention is that these matters should not be made an advertisement of, nor should they be distributed broadcast through the post We can only adjure all medical men to abstain from all dealings with the Od Chem Co A trading concern which manages its business and tries to win approval for its wares by such infamous measures as we have referred to above should be boycotted and, moreover, we hope that it will [illegible] be very long before His Majesty's Postmaster-General will find some way of dealing with such filthy publications Surely they should come under the heading of Section 1 of the paragraph "Articles not allowed to be sent by Post' as laid down in the regulations published in the Post Office Guide Medical details which are in no way filthy when published as part of a scientific work *become so at once when part and parcel of an advertisement.*

A CHRISTIAN SCIENCE BURGLARY

THE New York correspondent of the *Daily Telegraph* states that Mrs Mary Baker Eddy's house has been ransacked by burglars and that many articles of value including gifts offered to Mrs Eddy by her followers, were stolen It will be interesting to see whether or not Mrs Eddy applies to the police or whether she will just think that she has not lost anything, for this, we imagine, is the orthodox Christian Science treatment of disease and evil

THE VAGINAL DOUCHE

To the Editors of THE LANCET

SIRS,—From time to time various modifications and improvements [illegible] There is an erroneous principle that [illegible] opening at the point of [illegible] he tube in position. Let two ounces of water be injected Then there is round the cervix a cavity containing fluid in which the nozzle is lying No fluid runs out, for the vaginal opening remains closed round the tube and probably more than four or five ounces will be injected before any fluid begins to flow At this point, therefore, there is fluid in the closed cavity under some considerable pressure The pressure acts equally in all directions the force at the opening of the cervix being equal to that at the opening of the syringe It can easily be seen what will be the result of vigorous syringing especially if the two openings are in a line with each other as must at least sometimes happen The object of vaginal douching is in general to wash out the vagina There can hardly be a doubt that in some cases gonorrhœal peritonitis is brought about by awkward syringing, the infection being thus conveyed directly into the uterus When a woman has any increased discharge she goes straight away and buys a syringe, and when the mischief is done she comes into the consulting room For further possibilities of harm see THE LANCET of Oct 3rd p 979 The ideal syringe-tube would be closed at the apex, there being one or two openings on the side close to the extremity, rounded or oval, and big enough to let the head of a hare-lip pin or bonnet pin through The material would be toughened glass or clear celluloid, shorter by one or two inches than the usual gum elastic tube and wider, so as to lessen the pressure within Perhaps one might ask for another name than the present cumbrous and indelicate term Something like "Re-lave, meaning to wash back, would be at once explicit and sufficiently euphonious

I am Sirs yours faithfully,

Earl's Court road, W, Nov 23rd 1903 GEORGE CRICHTON, M D Edin

ETON COLLEGE BEAGLES

A MEMORIAL has been addressed through the Humanitarian League to the chairman of the governing body of Eton College It is signed by the headmaster of the Handsworth Grammar School, by the honorary secretary of the Martock District of the South Somersetshire Branch of the Royal Society for the Prevention of Cruelty to Animals, and by some other better known gentlemen It has also, we understand, been signed by Lady Florence Dixie, Mr Keir Hardie, Dr Gordon Stables, and Mr Hopwood, the Recorder of Liverpool The Humanitarian League, "without entering on the general question of the morality of field sports as practised by adults,' desires the governing body of the college to do away with the Eton beagles The Provost has replied, stating that the governing body were not going to interfere with the headmaster's discretion The Rev J Stratton, secretary to the Sports Committee of the Humanitarian League, thereupon wrote to Dr Warre who with admirable common sense replied that he was not prepared to interfere with the liberty of the boys in the matter and that he had no evidence to show that in any single [illegible] for our own part, [illegible] are or does not [illegible] the authorities of the college decide that the exercise is good for the lads they will take care that it is obtained without any brutality to animals We object to the licence that bodies like the Humanitarian League allow *themselves The memorial is accompanied by a fly sheet* saying that "the Eton boys seek amusement in the infliction of pain on animals' The league has no business whatever to assume that it is the pain of the hare that amuses the boys, and such insinuations are constantly made by antivivisection societies and similar conceited ill informed bodies

A SPECTACLE QUACK

WE have upon many previous occasions referred to the injury inflicted upon patients with defective sight by their being drawn into the net of the "oculist optician" One of this fraternity, whose name is

Mr J Hamilton,
Bridge Avenue,
Hammersmith, London,

has recently been travelling in the West of England and has distributed circulars to medical men and presumably to others Two of these have been forwarded to us, one by a medical man at Sherborne and one by a medical man at Templecombe In one case Mr. Hamilton called for the circular himself The circular, we may add, is endorsed, "The forty seventh annual visit to this town,' and proceeds —

> MR J. HAMILTON respectfully announces to the Nobility, Clergy, and Gentry of this Town and its Vicinity his arrival, and begs to introduce his newly invented *CRYSTAL SPECTACLES* and *EYE GLASSES* celebrated for their superiority, a trial of which he feels confident must ensure unqualified approbation for the protection they afford to the Eye from the injurious effects of gas, fire, the sun or variations of the atmosphere
>
> In his long and widely-extended practice, MR HAMILTON has met with numerous cases of ruined sight, caused chiefly by the use of unsuitable or defective Spectacles, purchased of ignorant pretenders to optical science, who undertake to assist the sight with Glasses the properties of which they know nothing, and as they have not made the anatomy and physiology of the eye their study, they are not qualified to make that delicate adjustment of the Glasses to the concavity or convexity of the eye without which clear and easy vision is impossible
>
> [illegible] nify [illegible] not [illegible]
>
> *Single Eye Glasses should in all cases be avoided*
>
> Mr J HAMILTON will call personally to morrow, when he may be consulted on all Diseases of the Eye and Ear.
>
> CAUTION —*Mr J Hamilton begs to caution the Nobility and Gentry of this Town against any persons making use of his Name for Trade purposes He has no connection with any other person of the same Name, neither has he any Son or Nephew travelling — (Signed) J. HAMILTON*
>
> MR J HAMILTON HAS ALSO A LARGE ASSORTMENT OF OPERA GLASSES

Mr Hamilton is kind enough to give "a few testimonials from many hundreds' Most of the "testimonials are simply names and those names preceded by "Dr do not appear in the Medical Directory at the places where Mr Hamilton says that the owners live There are two testimonials one dated 1866 and one 1868

A FREAK OF HEREDITY

To the Editors of THE LANCET

SIRS —Will you allow space in your columns for the following notes and questions? The case to which they relate may be of interest to those who study the phenomena of heredity. My grand niece has a head of hair unlike any other I have ever seen outside my own family, each hair being twisted up separately and the whole standing out almost straight from the head when let down and combed The child's mother has similar hair, so has her grandmother, her great-grandmother had not but she evidently inherited and transmitted the tendency to it, for her brother showed the trait fully Going back

Communications, Letters, &c., have been received from—

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

An Address

ON

CONTINUOUS LOCAL INFECTION.

Delivered before the Bradford Medico-Chirurgical Society on Oct. 13th, 1903,

BY RICKMAN J. GODLEE, M.S. LOND., F.R.C.S. ENG.,
HOLME PROFESSOR OF CLINICAL SURGERY, UNIVERSITY COLLEGE, LONDON.

MR. PRESIDENT AND GENTLEMEN,—It is often borne in upon him who has himself mounted the hill with his fellows and like them begun the downward journey that many of the diseases of middle and later life are due to the absorption of small, it may be minimal, doses of poisons. He will be *sure to have a friend of temperate and domestic habits* who daily and without thought divides a bottle of champagne at dinner with his wife and at the age of 45 or 50 has a liver that reaches down to his umbilicus and is shocked to hear that he is the subject of alcoholic poisoning. Or it may be that he is the hungry dyspeptic who suffers not so much from the nature of the food which he swallows, although in this respect it is to be feared he is often far from judicious, but rather from the deleterious products which his imperfect digestion manufactures out of the materials which are for the eupeptic not only harmless but nutritious. Is it possible to doubt that many of the degenerative changes of middle and advanced life are due to this cause, just as they are to the poisons circulating in the blood of those who suffer from such definite morbid states as Bright's disease and diabetes?

It is not, however, to such well-recognised forms of chronic poisoning that I wish to draw your attention but to two or three which though common enough have not perhaps received the attention which they deserve. And I naturally turn first to the most fashionable disease of the present day—appendicitis. Probably all of us have been surprised at the amount of good which some patients experience from the removal of appendices which are apparently not very seriously diseased, say, for example, those in which the proximal end is contracted without being quite closed and the distal end is dilated. I found it difficult to give a rational explanation of what appears to be a fact, that such patients are not only relieved from the recurrent attacks of peritonitis, or the easily comprehensible chronic constipation which is so common, but from other general symptoms which are apparently unconnected with the local trouble; and that they often put on flesh and regain a condition of health to which for years they have been strangers.

The key to the situation appeared to be supplied by a case in which I was associated with my colleague Dr. Sidney Martin who has published it in the Transactions of the Royal Medical and Chirurgical Society, vol. lxxxiv., p. 197. A man, aged 50 years, had suffered more or less for eight weeks from intestinal symptoms which *started on his way back from a fishing expedition in Norway* in the autumn of 1899 There was no indigestion of food but there was gradual loss of appetite with final complete anorexia. There were a bad taste in the mouth and a dry tongue, with a deficient secretion of saliva. The motions, although not very frequent, were never solid and became more and more offensive and very offensive flatus was also passed. ugh in
the morn in the
motions. e was
under obs eek it
rose to 9 week
there was a similar slight tendency to rise. He was pale, cachectic, and much emaciated. The muscles were flabby and the wasting was continuous, so that he lost 11 pounds in 15 days, and in spite of treatment in bed, careful dieting, intestinal antiseptics, and douching of the colon with boric acid solution he seemed to be passing into a desperate condition. There was no distension of the abdomen and no tumour could be felt except something in the neighbourhood of the right kidney which it was thought might be no *more than this organ. The lymphatic* glands throughout the body were somewhat enlarged, the most marked enlargement being of those in the right groin. He had the *appearance of one suffering from malignant* disease and I was asked to see if this doubtful lump in the
r was not a carcinoma of the
l out to be the right kidney
but on exploring the surrounding parts the cæcum appeared to be thickened and an elongated and distended appendix, the presence of which we had, I think, none of us suspected, was pulled out into the wound and removed. Its proximal end was narrow but patent, the walls were enormously thickened except for an inch at the proximal extremity where there were two small erosions, and the contents consisted of horribly offensive liquid matter with a few fæcal concretions. Here was then presumably, as Dr Martin suggests in his paper, the real *fons et origo mali*—an automatic syringe squirting into the cæcum hour by hour and minute by minute not only the noxious products that the micro organisms produce but the micro-organisms themselves. I feel sure that the explanation is the right one, for although the recovery was slow it has been complete. There were a gradual disappearance of the symptoms and a *gradual recovery of strength. Ten months after the* operation he had attained his usual weight and now, more than three years afterwards, he is fat and well. The enlarged glands disappeared rapidly after the operation; and it is interesting to note that the gland in the right groin was obviously infected from a mass of old calcareous and recently inflamed glands which occupied the angle between the end of the ileum and the cæcum—that mass of glands which often forms a considerable part of the *lump* in cases of appendicitis. I removed some of them for microscopical examination but no organisms were found either in them or in the walls of the appendix.

The cases of recurrent appendicitis in which we hesitated to recommend radical cure used to be very numerous, in fact not many years ago they all belonged to this category. Now it dwindles and apparently approaches extinction, as we recognise how slight are the dangers of the operation and how perilous is the condition often met with in operating after the first attack. I make a point now of inquiring into the question of chronic septic poisoning and if there is any suspicion of it I consider it a strong argument in favour of recommending the removal of the probable source of the trouble.

In operating upon cases of appendicitis in the quiet stage we often meet with buff-coloured patches looking not unlike necrosed fat. Sometimes the interior is quite soft, sometimes it looks like actual pus. I am informed on good authority that the bacterium coli commune is to be found in this material. There can be little doubt that these yellow masses are the remains of abscesses. I remember once coming across such a deposit in the process of formation. The case had apparently commenced in the ordinary way but suppuration had extended across to the left side of the abdomen, where a huge collection of pus existed. Round the appendix, where there was a very slight swelling, there was a minute collection of pus which was evidently becoming inspissated but was separated by a considerable extent of peritoneal adhesions from the main collection in the pelvis and on the left side.

Probably in the majority of cases of relapsing appendicitis small abscesses are formed, I expect *that* quite appreciable collections of pus exist in many, but that they are absorbed by the peritoneum. For my present purpose it is interesting to inquire whether the patient suffers in any way from the presence of these inspissated abscesses, either because their contents are absorbed or because they are liable to light up again independently of fresh acute mischief occurring in the appendix. That this occurs sometimes is rendered highly probable by the fact that it is not uncommon in operating within a few days of the subsidence of an acute attack to meet unexpectedly with a small collection of pus. I have actually found in such an abscess the stercolith which had escaped from the appendix, although the lump had gone and the temperature had for days been normal.

One of the most important diseases of this class is *pyorrhœa alveolaris* and I make no scruple in referring to it, although it is now rather prominently before the profession and the public and I have already myself published something upon it.[1] It is important first because it is so common and so insidious; secondly, because its effects are so pernicious and so varied; and thirdly, because it is so difficult to cure that our friends the dentists are apt to give it up as a bad job. *Spongy gums* seem to be such a trivial complaint and the inconvenience is to many people—people who are not very particular—so slight that they seldom, unless the importance of it is pointed out by the medical attendant or the dentist, think it worth while to apply for treatment. The people who never wash their teeth seem to suffer but little from it, even when it is far advanced and their mouths are in a foul condition, though what their sensations must be I find it hard to conjecture. In our own walk of life the complaints usually made are: (1) that the gums bleed when the teeth are washed or when they are sucked; (2) that there is a disagreeable taste in the mouth; and (3) sometimes, but by no means always, that there is a large amount of expectoration which may have the appearance of pus mixed with saliva or be more or less deeply blood-stained. The patients will often tell you that it has not only a highly offensive taste but an offensive smell, though of this they are often quite unconscious. Anyone, however, who has once recognised the very disagreeable sickly odour which is associated with the disease has unfortunately only too often the opportunity of recognising its presence amongst his own acquaintances. It is often asserted most positively that this expectoration comes from the back of the nose or the throat or is coughed up from the lung and patients are only convinced that they have been mistaken when the disease has been cured or placed in abeyance. Occasionally the saliva or bloody fluid runs out from the mouth at night on to the pillow and this when it does occur is almost pathognomonic of the disease. If the expectoration be allowed to settle the deposit has a very close superficial resemblance to pus. It does, indeed, contain a certain amount of pus but by far the greater part of it consists of squamous epithelium which should at once suggest its source. It is perhaps not generally known that a small amount of fluid of this sort—I mean one looking like pus mixed with saliva—may be obtained by anyone, however clean his mouth, by sucking for a few minutes at his gums with the tongue. The signs of the disease are not very obvious if the patient is particular and brushes his teeth frequently; perhaps only a bright red line at the edge of the slightly retracted gums. I particularly want to emphasise the fact that such appearances are consistent with a very advanced stage of the disease. A very fine probe will very likely, even when there is nothing more to be seen, pass a long way between the separated gums and the fangs of the teeth and it is from these pockets that the noxious material is being constantly expelled into the mouth. In advanced cases when the patient takes no care of his mouth there is no difficulty in making a diagnosis. The extensive retraction of the gums which are obviously spongy and probably bleeding, the yellow line of fur and pus, the absorption of the alveolus and exposure of the fangs covered with tartar, the gradual loosening of the teeth, and the stinking mouth are quite unmistakeable.

---

[1] *Transactions of the Royal Medical and Chirurgical Society* vol. lxxxiii., p. 23.

Without attempting to summarise all that is known of pyorrhœa and before coming to the reason for including it in this paper there are two or three things more to be said: 1. It very often occurs in members of the same family, whether because it is hereditary, or infectious, or because the habits of the individuals are the same I do not know. 2. The fangs of the teeth, where they are surrounded by the pockets, are covered with tartar and it is impossible to cure the disease without eradicating these deposits. It is here that the chief difficulty of treatment comes in. The tartar is of two kinds, true tartar or salivary calculus consisting of phosphate and carbonate of lime with ptyalin and animal matter, and black tartar, dark in colour and of dense consistence. The relation of the tartar to the disease has been much discussed. By some it is supposed to cause inflammation of the gums by its presence and so to start the ulcerative process. By others it is supposed to be a secondary affair. For us it is important to remember that the black tartar is found on the fangs of the teeth right down to the bottom of the pockets. It was on the removal of this tartar that Dr. Riggs of Hartford, Connecticut, very strongly insisted in what was really the first rational suggestion for the treatment of the disease, and I do not altogether grudge his memory the name of "Riggs's disease" by which for long it was known. His treatment was by special powerful scarifiers and is said to have been painful but for a time successful.[2] 3 The disease usually starts in young adult life and if unrelieved will almost inevitably lead to premature loss of the teeth. 4. Controversy is still maintained as to whether or not it is often or ever caused by the gouty diathesis but the balance of evidence appears to be against this suggestion.

Now I will ask you to consider what it must be to be always swallowing day and night, year in year out, these septic organisms and their products. I can imagine an objector saying that the stomach is well able to give a good account of micro-organisms and that a mouthful of cheese contains more living inhabitants than does the continent of Europe, or urging that if the disease is so common we ought to see more of its results, or, again, that the human body is after all a joint stock concern and gets along very well with its associated organisms and, in fact, might be rather in difficulties without them. In order to answer these criticisms let us try to realise the actual state of things as far as modern investigations enable us to do so. An admirable work on "The Mycology of the Mouth" by Kenneth Weldon Goadby has appeared this year, in which he gives with careful detail his own observations as well as those of previous observers, of whom the best known are Miller and Galippe. It is there stated that the micro-organisms seen on direct examination may be tabulated as follows: (1) cocci, generally in diplococci, and massed around the epithelial cells in clumps; (2) thick bacilli generally jointed and often showing considerable irregularity in their staining characters; (3) thick bacilli with pointed ends and somewhat of the shape of a bean-pod (they frequently show a division in the centre and appear as two elongated triangles with the bases opposed); (4) various fine bacilli, $0{\cdot}5\,\mu$ and under in width, often exhibiting an irregular beaded marking, especially well marked in the larger threads which may be of great length; (5) spirilla, spirochætæ, and comma-shaped bacilli, all showing marked motility in the hanging drop; (6) various yeast forms, sometimes with a partially developed mycelium; (7) streptothrix threads, generally showing well-marked clubs; and (8) masses of bacilli associated with the threads, some jointed in chains, others free and often massed in clumps; some of them exhibit polar staining. Many of these organisms obtained in pure culture are pathogenic to animals, but it is remarkable that the best observers agree that the common pus cocci only occur in about 10 per cent. of the cases examined. Cocci, indeed, are found in all cases, but it is supposed that they are not precisely the same as the pus cocci. Be that as it may, it is clear that a vastly larger number of pathogenic organisms, and probably in a much more active state than normal, are constantly being swallowed. The stomach no doubt can deal with a good many organisms by virtue of the hydrochloric acid in the gastric juice. But there are many organisms which it will not kill—such, for example, as the typhoid bacillus—and it has not been ascertained how far the pathogenic organisms of the mouth are affected by it. They come down in great numbers and the re-resisting power of numbers is greater than the resisting powers of a few; in other words a concentrated dose is more effectual than a dilute one. They come down too at all times of the day, both when the stomach is full and contains hydrochloric acid and when it is empty and contains little or none; and Dr. William Hunter considers that he has demonstrated[3] that in cases where there is profuse purulent discharge into the mouth the pus cocci become permanent residents in the stomach after producing what he calls septic gastritis. Lastly, it is impossible to say why one person suffers from septic poisoning and another escapes, just as it is in the case of the exhibition of other toxins, whether septic or not. It is the personal equation which we do not understand. It is the amount of resistance that is greater in one individual than in another or is greater in the same individual at one time than at another, depending on the state of his bodily health at the time.

I now pass on to enumerate the diseases which have been supposed to be caused by pyorrhœa and other forms of oral sepsis, a long account of which is to be found in Hunter's paper and in the writings of others. They include septic fever, rashes, and profound septicæmia, purpuric hæmorrhages and bleedings from the gums, toxic neuritis, septic gastritis, stomatitis, pharyngitis, and tonsillitis, ulcerative endocarditis, pernicious anæmia, chronic dyspepsia, bronchiectasis, &c This is a sufficiently formidable list but not, I am sure, a complete one

---

[2] Some dentists have recently denied that tartar is always present.

[3] Oral Sepsis as a Cause of Septic Gastritis, Toxic Neuritis, and other Septic Conditions, Practitioner, December, 1900.

I desire, however, to draw attention not only to the diseases which pyorrhœa may cause but also to those which it may simulate I reported three instructive cases in the paper above mentioned and to these, with one or two others, I will briefly refer

CASE 1 —The patient was a woman aged 45 years, with a long history of previous illnesses dating back to 1881, including a miscarriage, a bad confinement, uterine displacements, vaginal discharge, floating kidney, shivering fits and headaches, and five or six attacks of influenza with chest and bronchial troubles The expectoration began in 1897 and was at first green and then bloody and offensive The diagnoses made were pleurisy followed by a small empyema, pleurisy followed by bronchiectasis, and subdiaphragmatic abscess connected with the right kidney and bursting into the lung But there were no abnormal physical signs except slight retraction of the right posterior base with lessened movement, some increased resistance on percussion, and weak breath sounds Her principal complaint was the extremely offensive expectoration, amounting to five or six ounces in the 24 hours, not exactly coughed up but hawked up from the back of the throat a foul taste, and breath offensive to others The teeth were very carefully attended to and only showed the red line and slight retraction of gums to which reference has been made, but the pockets were numerous and deep All her troubles were removed by the effectual treatment of the gums Her daughter suffers from the same complaint

CASE 2.—The patient was a woman, aged 25 years, who had a well marked attack of right pleurisy in March, 1899 Expectoration began at the time of this illness and became bloody six months later and was always offensive It was brought up in the same way as in the last case She had lost flesh and perspired at night and was very anxious about her state and especially about the foul taste in her mouth and offensive smell of her breath A few physical signs resulting from the old pleurisy remained at the right base and I was requested to open a supposed abscess of the lung in this situation She had very marked pyorrhœa and was at once relieved on treating the gums Her sister suffered from pyorrhœa

CASE 3 —The patient was a man, aged 66 years, who had very marked pyorrhœa round his few remaining teeth He had suffered from three or four mild attacks of diarrhœa in quick succession when he was seized with an acute attack of glossitis and stomatitis with profuse and offensive salivation The gums became much more swollen and the suppuration copious The tongue was enlarged and thickly coated. Superficial ulceration appeared at several spots where the teeth impinged on the lips and under surfaces of the tongue There was for a few days considerable fever He also rapidly improved under vigorous treatment of the gums

CASE 4 —Dr Martin supplied me with notes of a case which was supposed to be cancer of the stomach depending on the same cause

CASE 5 —A woman was sent with obscure abdominal troubles which it was thought might be relieved by fixing the moveable right kidney, though her symptoms depended only on pyorrhœa

There are, however, other reasons why pyorrhœa is important to surgeons I need not remind my surgical colleagues of the importance of treating it thoroughly before undertaking any operation upon the mouth nor how much the mortality of operations on the stomach, the tongue, and the jaws has been reduced since a careful toilet of the mouth has been recognised as an essential preliminary I have always a supply of tooth brushes and Miller's excellent mouth wash at hand in my wards for all comers and direct the sister to inquire into the state of the patients' mouths and to deal out the tooth brushes when necessary Then I have seen quite a few where the disease has been mistaken for chronic pharyngitis diseases of the antrum, and other inflammatory diseases of the mouth and naso-pharynx Lastly, we must examine ourselves periodically and see whether we are the subjects of this disease, for it must not be forgotten that we become dangerous to the community if we have not clean mouths A short-sighted or over eager surgeon may spoil the effects of the most elaborate antiseptic preparation of his patients by breathing or coughing on to the surface of a wound; an irritable or didactic one may by injudicious speaking during an operation positively put his patient's life in danger, in fact, I have more respect for the practice of some surgeons who always antisepticise their mouths before an operation and wear a mask and rigidly refrain from speaking during its performance than for some of those elaborate details which almost seem like bowing down to, and worshipping, a fetich

One word must be said about the treatment It does not, of course, rest with us but with the dentists who have carefully and repeatedly to clear away the tartar from the fangs and then to attack the organisms contained in the pockets either by syringing or packing using such antiseptics as peroxide of hydrogen, chloride of zinc, or essentials oils and sometimes freely slitting up the pockets in order to gain access to the mischief and give free exit to the pus I regret to say that some dentists I have sent patients to have treated the notion that pyorrhœa could possibly cause such symptoms as I have described as moonshine or have plainly told the patients that they are incurable or have advised the extraction of all the teeth The last is certainly effectual but it is rather a strong measure and I know from ample experience that with patience and perseverance on the part of the patient and the dentist very much may be done without proceeding to the *ultima ratio* But it must be added that the problem of the effectual treatment of Riggs's disease amongst the poor has not yet been solved and I would earnestly commend it to the attention of scientific dentists I suggest that it will be found in making freer incisions into the gums so that the pockets can be done away with, treating them, in fact, like ordinary abscesses and then supplying the patients with good hard tooth brushes and some cheap but efficient oral bactericidal mouth wash It is not too much to hope that in otherwise unexplained cases of chronic septic poisoning we shall all get into the habit—that is the important thing—of critically examining the gums and insisting upon the treatment of this most insidious complaint

Amongst the conditions in which small amounts of pus or morbid products are constantly leaking into the system are some to which a brief reference only can be made The most striking amongst these is the development of lardaceous disease in the subjects of chronic suppuration A great deal is known about the morbid anatomy and chemistry and symptoms of this disease but remarkably little about its pathology All however, seem to be agreed that almost all the cases depend either upon prolonged suppuration or upon syphilis and that in many of the syphilitic cases suppuration is also present It is, indeed, almost hinted in the last edition of the ' Principles and Practice of Medicine" by Fagge and Pye Smith that it may ultimately be found that all will fall into one or other of these two categories They say "Many writers speak of scrofula, chronic tuberculosis, cancer, malaria rickets, and syphilis as being alike *constitutional diseases which predispose to the development of lardaceous degeneration*," and to these we must add some forms of kidney disease and lymphadenoma. They continue "In the first place, it is doubtful whether scrofula, or otherwise the presence of tubercle in the lymph glands or joints, *has any influence apart from its tendency to cause suppuration* In the second place it is certain that syphilis leads to the lardaceous change even when the formation of pus has occurred only to the most insignificant extent if at all We may therefore reduce the known causes of the lardaceous change to two—chronic suppuration and syphilis, sometimes combined but capable of acting separately" In 1876 Fagge brought before the Pathological Society an account of 244 cases collected during 24 years at Guy's Hospital Of these 153 were due to prolonged suppuration divided as follows phthisis, 67 cases, joint or bone disease, 51 cases; chronic diseases, dysentery, &c, 36 cases, very slight suppurations, such as chronic discharge from the ear and nose, suppuration of one testicle, caseous glands, &c, five cases This very interesting series of cases is brought up to the year 1899 by your last President Dr H J Campbell The total amount then reached 546 and of those only 19 remained unaccounted for by anatomical evidence of chronic suppuration or syphilis Of these 19 the post-mortem notes of six, at all events, are unsatisfactory and in all there must be the difficulty of excluding syphilis The remaining 13 died from miscellaneous diseases the relation of which to lardaceous change is not obvious

I do not want to ride my hobby too hard but is it too fanciful a suggestion that the mouth should be carefully searched in cases where lardaceous disease occurs without obvious cause? Each suppurating cavity round a tooth fang is, of course, a small one, but if they were added together the discharging surface would be one of considerable size and I can quite imagine that lardaceous disease may have to be added to the list of those depending on pyorrhœa alveolaris and other forms of oral sepsis.

The actual manner in which lardaceous disease is produced by chronic suppuration has yet to be determined, for we can hardly consider the question to be finally settled by the interesting experiments of Dr. Alan B Green (communicated to the Pathological Society by Mr. T. Strangeways Pigg on Feb. 6th, 1900, in a paper on the Production of Amyloid Disease in Animals). His method was to inject rabbits subcutaneously, intravenously, or peritoneally, or to inject into the pectoral muscles of hens one cubic centimetre of a broth culture of staphylococcus pyogenes aureus, the dose being repeated and gradually increased until toleration was established. Only a few animals survived for any length of time, but some of the rabbits lived for three, four, or five months, and one hen lived for 15 days. The organs after death showed appearances which were supposed to indicate lardaceous changes. It must be owned that the conditions thus produced were not very similar to those in which lardaceous changes are developed in man and that the results are not quite convincing, so as no further experiments have been reported up to date, we are still uncertain whether lardaceous degeneration is caused by some such process as was suggested by W. H. Dickinson in 1867—viz, that the draining away of alkaline salts by the pus transformed fibrin into lardacein—or whether, as is more likely, it is caused by the re-absorption of some of the products of the micro-organisms by the walls of the cavities in which the suppuration is occurring. It may be, indeed, that neither of these is the correct explanation.

Some peculiar points about lardaceous disease cannot fail to strike the clinical observer: (1) that whilst some individuals may remain free from it for many years who suffer from a chronic issue of pus others develop the disease and fall victims to it in a comparatively short space of time; (2) that though it is very often associated with clubbing of the extremities the two conditions may occur singly or one may precede the other by a long interval; and (3) that if the cause of the disease is removed an almost complete recovery may take place even when the viscera have been profoundly affected. I have seen, for example, a young man with a chronic empyema of small size which had been imperfectly drained and was still discharging; his liver was enormous, his urine became solid on boiling, and his fingers were tremendously clubbed. A free incision into the empyema led to its closure in a few weeks and all his symptoms and signs disappeared except that he never quite lost all traces of albumin in the urine whilst he was under observation although some samples were free from it.

I have under my care at the present time a tuberculous patient, 46 years of age, who has had an empyema running for 15 years or more but which was always very freely drained. He has enormously clubbed fingers but there is no albumin in the urine and there is no obvious enlargement of the liver. He has had attacks of albuminuria which have passed off and he has also had attacks of synovitis of the knees which have subsided, but he certainly has no characteristic signs of lardaceous disease. I attribute this to the free escape for the discharges which has always been maintained, and I think it is important, if we are driven to the conclusion in any particular case that a source of suppuration cannot be stopped, to maintain the most thorough drainage possible, in spite of the entreaties of the patient to be relieved of the bother of drainage-tubes; for I think it is in cases where the pus is confined that lardaceous disease is most rampant. A confirmation of this idea is to be found in the fact that all pathologists allow that lardaceous disease is far less common than it used to be before the modern improvements in surgery were introduced.

It is of course, a matter of every-day observation that the amount of absorption from the walls of an abscess is very much modified by the freedom of the escape of the pus; the immediate onset of symptoms of septic absorption when the exit becomes blocked is as familiar to everybody as is the rapid disappearance of such symptoms when either an acute or a chronic abscess is freely incised. There is another illustration of the same fact but of a totally different nature to which I do not recollect having seen any reference. I refer to cases where a septic abscess has existed under high tension without producing any serious symptoms, but where free evacuation has been followed by very rapid and even fatal septic absorption, presumably from an increased vascular flow through the pyogenic membrane. That such increased vascular flow is the immediate result of incision is shown by the copious and sometimes serious bleeding that follows the incision of acute or even chronic abscesses. Is it not then thinkable that the walls of a chronic abscess if imperfectly drained may absorb more readily than those of one in which the discharges are never allowed to accumulate? To illustrate my meaning I will mention two very striking cases. One was that of an old lady over 70 years of age who many years ago had an abscess connected with a perforated appendix which was left longer unopened than would be the case nowadays, but whose condition was quite good at the time of the incision. She rapidly died from septic absorption as soon as the pus was let out. The other case was that of a child with general peritonitis from the same cause, upon whom I only operated at the urgent request of the parents as she seemed to be *in extremis*. She, however, got better and seemed to be on the road to recovery, but after some weeks a left subdiaphragmatic abscess formed. Its evacuation was rapidly followed by a fatal result and I have seen the same thing happen after operating on very septic abscesses of the liver and other parts of the body.

Originating from similar causes to those which give rise to lardaceous degeneration is the disease, or rather are the diseases, known as pulmonary osteo-arthropathy, in regard to which I would only reaffirm my belief that more than one condition has been included under the description, and that the ordinary case (if I may be allowed the term) is a combination of clubbed extremities and septic osteo-arthritis. That the chronic septic poisoning is an important factor will be allowed by anyone who has observed a case develop, and still more readily by one who has attended, as I have done, at a cure. I have watched a man with this complaint who had an unopened empyema of long standing, urging him to allow me to lift his burden which he sullenly refused. At last perforation into a bronchus occurred and he expectorated the empyema and rapidly lost all his symptoms of pulmonary osteo-arthropathy and at the same time his disagreeable temper, for, although he still takes credit to himself for his cure and I believe has stated that I am but a poor doctor, he is now quite sweet-tempered and seems to be very grateful for all the attention he received in the hospital, for which at the time he showed little or no appreciation. Let it not be forgotten that pulmonary osteo-arthropathy of the type I am describing is a curable disease if the *causa causans* can be tackled, but as this is generally bronchiectasis or some other incurable condition the prognosis is usually hopeless.

The *septic osteo arthritis of young women often accompanying leucorrhœa*, and with which the name of the late Dr. Ord is associated, and the various forms of gonorrhœal rheumatism are matters of common knowledge and must not now delay us, though they clearly belong to the same class. I will only point out that the original cause of the mischief is, in my experience, frequently overlooked, especially if it be leucorrhœa, and I would urge the importance of inquiring into and treating it. It seems irrational to attempt to treat the joint disease without first attacking the source of infection.

I now pass to another group in which the morbid material has no obvious access to the general circulation or digestive or genito-urinary tract but remains for a time apparently encapsuled. Everyone must have observed that some, though not by any means all, patients with chronic tuberculous glands in the neck are always ailing—are in an indefinite state of ill-health—even though the glands may not be discharging. An operation is perhaps undertaken, partly for cosmetic purposes, partly in obedience to the teaching (which dates back certainly to the time of Niemeyer and perhaps even earlier) that the presence of cheesy (tuberculous) deposits may be under conditions of lowered vitality the source of a general tuberculous infection. And after the operation such patients often become quite robust. Now although it must be allowed that they are usually at the time of life when, even if nothing be done, there is a tendency for the body to become stronger and to get the better of tuberculous tendencies, the improvement is usually too rapid to be accounted for in this way. There seems to be some chronic poisoning going on, some secretion from these glands analogous to the internal secretion of such organs as the thyroid and the testicle, and this is I think a strong argument in favour of the removal of cheesy glands when they can be all got away.

It is amazing how long these tuberculous deposits may remain in an apparently quiescent condition. I had under my care a delicate middle aged lady who had recurring attacks of suppurating glands in the left side of the neck and cheesy glands in the left axilla. After many operations on the neck she encouraged me, when tackling the axillary glands, to remove a small hard lump in the breast of the same side which she told me Mr. John Burkett had seen 30 years before and told her it would never give her any trouble, no doubt taking it for a fibro adenoma or for chronic mastitis. It turned out to be a tuberculous abscess with calcareous walls which not improbably had a good deal to do with the development of the glands in the posterior triangle and her constant ill-health.

In this connexion I would refer to a man, 46 years of age, whom I first saw in 1901. He had never had good health and was always thin but had become much thinner—in fact, he was strikingly thin. For 23 years he had suffered from "crampy pains in the left hip if his bed was uncomfortable." For three years he had had lumbar pain, supposed at first to be lumbago, and pains in the left hip, and they had gradually become worse. His digestion was miserable and his circulation was very poor. He had an old lateral curvature, possibly due to an attack of pleurisy seven years previously. When I saw him he had a huge psoas abscess connected with caries of the lumbar spine. It was opened and treated in the ordinary way and he was kept on his back for a year. As soon as the abscess was opened he began to get better, his digestion rapidly improved, and at the present time he can eat almost anything. He quickly put on flesh and is now a very fat man. He has lost several nervous symptoms which previously troubled him and his old friends would hardly recognise him. Arguments about medical matters are notoriously liable to fallacies and it must be stated that he says his family usually get fat at about the age of 40 years, but I cannot doubt that he had had some pus pent up for many years and that the evacuation of this had much to do with the really extraordinary change in his condition that has taken place.

Another very remarkable case of a more acute type was that of a boy, seven years of age, who came under my care at the hospital on Jan. 24th, 1900, with *acute infective osteo-myelitis* of the right femur. A six-inch incision on the outer side of the thigh gave exit to a large amount of pus and it was found that the periosteum had been widely stripped off. A hole was made into the medullary cavity which was apparently healthy. Suppurative pericarditis rapidly followed and four days later the pericardium was opened and drained through an incision in the fourth left intercostal space by my colleague Mr. Raymond Johnson in my absence. Then acute suppuration of both elbows occurred, of which the right was incised on Feb. 4th, while the other slowly recovered without operation. He had also symptoms pointing to embolic abscesses in the lungs. On Feb. 16th he complained of headache. Double optic neuritis and other symptoms of abscess of the brain but without localising symptoms followed, but as the wounds closed the headache disappeared though the optic neuritis did not clear up. He left the hospital on May 15th with the pericardial and elbow-joint wounds closed but with a sinus leading down to bare bone in the thigh. He was cheerful and well but the temperature was not regular, sometimes running up to 100° F. and at the end of this period falling below normal. In a fortnight (on May 31st) he came back with headache and vomiting. Localising symptoms, consisting of weakness and ataxy of the left side of the face and body, and weakness of the right external rectus showed themselves on June 26th, and on the 28th a large abscess was opened behind the right fissure of Rolando, the odourless contents of which contained staphylococci. A large hernia cerebri formed. There was no improvement in the paralytic symptoms but there was a gradual return to health and the optic neuritis to a great extent cleared up by September. The temperature, however, remained a little erratic, occasionally rising to 100°. He now left the hospital and used to show himself from time to time, a fat happy boy, limping in on his crutches, for the hemiplegia did not improve and contracture set in. The hernia cerebri still formed a prominent tumour which was protected by a metal plate, and all his wounds, even that in the thigh, ultimately completely healed. And then on April 5th, 1901, after more than six months, he came back again with further symptoms of cerebral abscess which was opened after removing more of the bone. It was drained and irrigated but without avail and he died nearly 18 months after the onset of the disease. At the necropsy the scar of the original incision of the thigh was found to conceal a small abscess two and a half inches long by three-eighths of an inch wide in which lay a sequestrum completely separated from the greatly thickened femur. Is it possible to doubt that this abscess was the home of the staphylococci which were constantly poisoning his system? And is it not conceivable that if this wound had not unexpectedly healed and I had removed the sequestrum in the usual way he would have made as good a recovery as such cases not infrequently do?[4] One is here reminded of the long intervals that elapse between an attack of typhoid fever and the development of necrosis and one wonders whether the presence of the typhoid bacillus in the system is quite without any deleterious effect upon the patient in the meantime. And it is impossible to forget how long a liver abscess may remain dormant and how wretched the patient's health often is whilst it is in this condition. That small sequestra may remain dormant for a very long time was pointed out by Page[illegible]et necrosis" well expresses the [illegible] do apparently little or no harm [illegible] but that they are a real source of danger is perhaps not so generally recognised. I will now describe a case which illustrates this point in a forcible manner although the mischief here was less of a general kind than in most of those which form the subject of this paper.

In October of last year I saw a man, who was then 47 years of age, whose family history may be said to be tuberculous and who 40 years before had had necrosis of the lower end of the left femur. Whether it was acute infective osteomyelitis or tubercular it would be, of course, impossible to say. He was seen and operated upon by two most distinguished surgeons, whose names are now household words, and the wound healed and remained healed for years. 12 years before I saw him another distinguished surgeon had dealt with another abscess and had found much bare bone but no sequestrum. During all these 40 years he had numerous abscesses, but the interesting point is that they healed completely and in the intervals he could do a considerable amount of athletic exercise. The return of the abscesses became more frequent as time went on and at last occurred almost annually; each one was ushered in by acute fever and was accompanied by synovitis of the knee. The most serious attack of all was the one for which I attended him. During this the knee-joint suppurated and his life was in much danger. Free incisions into the joint, however, enabled us to save the limb and on a later occasion I made a careful exploration of the femur and there, embedded in an enormous mass of callus, were three or four small old sequestra, dating back, I have no doubt, to the original attack and which for all these 40 years had remained as possible poisoners of his system whenever a state of impaired vitality gave them a chance to invade it. Had the search for these sequestra been successfully carried out 39 years before how different would the best years of this man's life have been. Far be it from me to suggest that at the time it would have been possible or to impute any want of skill on the part of the surgeons who preceded me. For I am well aware how well-nigh impossible it is in some cases to discover such minute sequestra; and if I had been more modest I should have chosen a case in which I myself had given up the search in despair. It would have been easy to do so, though not to produce quite such a striking example. It is, moreover, exactly the case which I wanted in order to bring this paper to a close. a paper in which I have brought together a variety of subjects, differing in all sorts of ways, but all linked together by one idea—namely, that widespread disorders may depend upon small infections acting sometimes unperceived over long periods of time and that neglect of observing the cause may lead to the adoption of erroneous lines of treatment.

---

[4] His heart weighed ten ounces. The pericardium was adherent but not thickened. The right lung was adherent to the chest wall by [illegible] and the left by scattered adhesions. The ventricles of the [illegible] ningitis. [illegible] he right [illegible]

It will not do for us to say, like our brethren of the long robe, "*de minimis non curat lex.*" The smallest things for the medical man are often of paramount importance. Why, the whole of modern surgery and a great part of modern medicine are based upon the study of objects so minute that they were a generation ago either quite unknown or looked upon as the curiosities of the microscopist. I do not pretend in any way to have exhausted the subject. I have dealt with it chiefly from the surgical side, but I feel that a physician might easily have said as much or more from his own point of view. I trust, however, that what has been said and suggested may prove not quite uninteresting and open up some fruitful lines of thought.

I met the other day a distinguished Yorkshire surgeon who said he was going to do me the great honour of coming to hear me to-night. I told him I was going to talk about little drops of pus. "Pus," he said, "we never see pus." Well, I always take a statement about never seeing pus with a grain of "salt," as I know those who make it intend it should be taken, for we must all see pus in abundance unless our practice is of a very limited nature. But I know what he meant. It is not, however, the pus that we see that I am now urging the importance of. He put the emphasis on the word *see:* I put it on the *little drops.* I am pointing out the subtle influences of the pus that we do not see, of the pus we have to go in search of, or even to recognise the existence of by a process of ratiocination, the unseen pus that walketh in darkness and wasteth at noonday. I am urging the necessity of not treating unexplained septic symptoms without searching for their cause and of remembering, as Jenner used to say, that we miss more by not seeing than by not knowing, and that while nature sometimes seems to spread her book wide open to our gaze she more often hides her secrets and for their disclosure demands our deepest thought and most painful scrutiny. So that for him who has failed to search her out and to meet her advances the "*history*" will for ever have remained a "*blank*" because—

"She never told her love,
But let concealment, like a worm i' the bud,
Feed on her damask cheek."

ABSTRACT OF

A Clinical Lecture

ON

A PATIENT WITH MITRAL STENOSIS.

Delivered before the Students at the Bristol Royal Infirmary, on Nov. 14th, 1903,

BY HENRY WALDO, M.D. ABERD., M.R.C.P. LOND.,
PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

GENTLEMEN,—This female patient, aged 31 years, unmarried, is the subject of valvular disease of the heart dating back five years only when she had an attack of rheumatic fever. It is chiefly the mitral valve which is involved. In the large majority of cases of mitral valve disease the left auriculo-ventricular orifice is distended but in this patient it is just the reverse for the left auriculo-ventricular opening is contracted. It is a case of mitral constriction or stenosis. In this pathological condition women are much oftener affected than are men. The etiology of mitral stenosis is that an inflammation of the mitral curtains is set up, a valvulitis or an endocarditis, from some cause which in some cases is ill understood, but in the majority of cases, as in this one, it consists of the rheumatic fever poison. When a child contracts rheumatic fever the affection of the joints and the fever may be very slight and easily overlooked. You will understand from this how difficult it is in some cases to get a history of rheumatic fever, and as a matter of fact the distemper sometimes expends itself solely upon the cardiac organ. As you know, girls are more liable to rheumatism and chorea than are boys and so it is we think that the female sex suffer so much oftener from mitral valve disease. In a few cases endocarditis may be set up by other febrile conditions, such as scarlet fever, or measles, or whooping cough, and the wonder is that patients with this last malady escape as they do, for the strain on the heart valves must be very great. Perhaps a very small percentage are congenital. Later in life mitral stenosis is associated with chronic kidney disease. The amount of constriction in cases of mitral stenosis varies very much, as well as does the shape of the opening. In extreme cases the opening from the left auricle into the left ventricle will scarcely admit a crow quill. I have seen valves in this condition. The most common shape of the opening resembles a button-hole and is well known as the "button-hole mitral." The valve is sometimes funnel-shaped, with the cone extending into the ventricle. The endocarditis extends from the valve segments to adjacent parts and we find the chordæ tendineæ are thickened and glued together.

The diagnosis of mitral stenosis is in the large majority of cases most reliable and if the physical signs are well marked you may feel confident about the condition of the valve, although you can never go so far clinically as to say whether the orifice is of the button-hole or infundibular shape. In listening for the characteristic presystolic murmur put your stethoscope over the area of the cardiac impulse. This murmur is usually very circumscribed and not conducted as a mitral regurgitant murmur is. It is rough in quality, extends all through the diastole or only during the latter part of it, as in this case, and ends abruptly in the first sound or in a systolic murmur which replaces the first sound. The rhythm is well described as thumping. We speak of a pure presystolic murmur when it is unaccompanied by a systolic murmur. Balfour thought that there was always a certain amount of regurgitation in all cases of mitral stenosis, although not necessarily accompanied by a systolic murmur. If we ask this patient to walk up and down the ward you will hear the presystolic murmur more clearly. We imagine that this murmur is produced by the left auricle, with its hypertrophied wall, contracting, which it normally does, just before the ventricular systole and so it is often spoken of as an auricular systolic murmur. It is also called the crescendo murmur of mitral stenosis. When you are listening to it keep a finger on the area of the cardiac impulse which enables you to time the murmur correctly.

There is in this case a systolic murmur heard inside the left nipple also which is, I think, conducted from the tricuspid valve. If it were mitral you would expect the cardiac impulse to extend outwards beyond the left nipple; the left ventricle would be hypertrophied and dilated but there is no evidence of this. You will notice that the second sound is inaudible at the apex which I have often noticed in other cases. In pure mitral stenosis the left ventricle is not enlarged; theoretically it should be smaller than in health, for it certainly receives less blood to deal with in consequence of the contracted mitral valve. In the late stage of these cases when the left auricle is very distended and the right ventricle fails to equalise the circulation the presystolic murmur disappears. The cardiac dulness to percussion extends to the right very considerably and not at all to the left. Owing to its breadth the heart has been likened to that of a turtle. The enlargement is due to the increased size of the auricles and right ventricle. The strain on the right side is so great in some cases as to induce chronic endarteritis of the branches of the pulmonary artery. Osler has seen two cases of paralysis of the left vocal cord caused by pressure of the enlarged left auricle on the left recurrent laryngeal nerve. If you place your hand over the seat of the cardiac impulse you will perceive a quivering sensation which is the presystolic valvular thrill. It is more marked during expiration and also after the patient has moved about the ward. It is a very important sign in confirming your diagnosis.

The pulse in this patient is infrequent and regular; in a more advanced stage it would be small, frequent, and irregular and some of the heart beats may then be imperceptible in the radial arteries. You will see clearly that this contracting mitral valve forms a diaphragm and so causes obstruction to the circulation in proportion to the size of its opening; there is in consequence more or less blood stasis which favours blood clotting. This is most likely to occur in the auricular appendices and pieces of this blood clot are liable to be carried with the blood stream until they are arrested, forming emboli. It is also thought that the blood may solidify in the vessels themselves, forming thrombi. When these emboli or thrombi are present in the vessels of the lungs they are the origin of infarcts and account for the attacks of hæmoptysis which these patients are so subject to. This patient has had several. The bleeding from the lungs is of course influenced by the increased blood pressure, the result of hypertrophy of the right ventricle. The emboli which find a lodgment in the systemic arteries are either pieces of vegetations from the mitral valve or broken up blood clot, usually from the left auricular appendix. These emboli not infrequently fix themselves in the cerebral arteries, usually in those of the left cerebral hemisphere, as being a more direct course from the aorta, and so explain the symptom which we call hemiplegia. So far this patient has escaped this form of paralysis. Embolism may sometimes be suspected in the renal vessels by the patient passing blood in the urine. In mitral stenosis the urine is usually scanty, as the renal vessels are inadequately supplied with blood and the arterial pressure is low.

Dropsy does not occur so often here as in cases of mitral insufficiency and it is not unusual when it shows itself to begin as ascites. The liver is often enlarged and tender and sometimes extreme pain is complained of in this region which depends upon stretching of the liver capsule. The deficiency of the circulation in the stomach and the bowels may give rise to indigestion and even to hæmorrhage.

The imperfect circulation through the brain would account for the sleeplessness which these patients frequently complain of. Bronchial catarrh is very easily set up on account of the abnormal moisture in the lungs. If the hepatic veins are much dilated a pulsating liver may be present. The blood tends to accumulate on the right side of the heart, notwithstanding Sansom's assertion that the circular muscular fibres in the pulmonary veins exert a powerful sphincter action, which, he says, can be demonstrated, and that it assists in keeping the backward blood pressure away from the lungs in cases both of mitral stenosis and mitral regurgitation.

In giving a prognosis a most favourable sign is a well-marked second sound heard at the pulmonary area, which is sometimes reduplicated. The closure of these cusps is sometimes so forcible that they can be felt by the hand in the second left interspace as a shock. This means that the hypertrophy of the right ventricle is well maintained and in association with this there is a pronounced pulsation in the epigastrium.

In treating these patients rest in bed is often necessary; they should at any rate be cautioned not to over-exert themselves. If the venous system is very full of blood opening a vein in the arm is sometimes a good palliative. In this condition of an over-distended venous system no drug is more valuable than blue pill, given perhaps in conjunction with enough compound colocynth pill to produce a watery evacuation. Compound jalap powder is useful for dropsical complications. When the pulse becomes very weak and frequent cardiac tonics are indicated and strychnia or digitalis should be given. If the urine is very deficient the best cardiac tonic to give would be caffeine which is stronger and better than the citrate of caffeine. Insomnia is frequently a troublesome symptom in these cases and it may be necessary to prescribe chloralamid occasionally at bedtime. Easily assimilated, light nourishment is all important, but see that all the food you give is digested, for although sudden death is a very [illegible] mitral stenosis it may be induced [illegible] and so allowed to press upon [illegible] cardiac pain is best relieved by advising very little fluid to be taken. A little alcohol is usually required in treating these cases.

THE MAIDA VALE HOSPITAL AND HOME FOR INCURABLE CHILDREN.—The President of this institution, H.R.H. the Duke of Connaught, occupied the chair on the evening of Nov. 25th at the festival dinner in aid of the charity in the Prince's Restaurant, Piccadilly, W. They had met, said His Royal Highness, in the interests of incurable children of the poor who by reason of the nature of their infirmity could not be received in the large hospitals and could not be properly looked after in their humble homes. There were 30 children in the home—15 boys and 15 girls, but more room, better air, and greater nursing facilities were needed and it was proposed to remove to a superior home in South Hampstead. The cost of the transfer would exceed £12,000, towards which £6000 had already been subscribed, and for the other £6000 he appealed to the company present. It was afterwards announced amid cheers that the sum of £5400 had been subscribed at the dinner.

ON THE PRESENT TREATMENT OF THE ENLARGED PROSTATE.[1]

BY C. MANSELL MOULLIN, M.D. OXON., F.R.C.S. ENG.,
SENIOR SURGEON TO, AND LECTURER ON SURGERY AT, THE LONDON HOSPITAL; EXAMINER IN SURGERY AT THE UNIVERSITY OF CAMBRIDGE.

THE duty of the person intrusted with introducing a discussion upon a clinical subject such as the treatment of enlargement of the prostate is not so much to read an exhaustive paper on it himself as to define those conditions of the affection which appear to him to be most likely to repay discussion, and to indicate the methods of treatment which, in his experience, are best suited to those conditions, and the reasons for selecting them. In accordance with this idea I wish to leave altogether upon one side all those cases in which catheter life is so successful that the patient manages to lead a comfortable existence by passing a catheter for himself once, or at the utmost twice, in the 24 hours. There is nothing more to be said about them any more than there is about those happy old men who are not even aware that they possess a prostate. The treatment cannot be called ideal. It merely concerns itself with one of the consequences of the enlargement and leaves the cause untouched. But if all the symptoms, both those that are present at the time and those that are likely to occur as the patient grows older, are adequately met by such a simple proceeding, and if the frequency with which the catheter has to be used does not increase as years pass by, it must be allowed that the treatment meets the necessities of the case sufficiently well. Such cases may be placed once for all upon one side. I have nothing further to say about them I am only concerned with the exceptions, those in which this line of treatment is either a failure from the first or is morally certain to become a failure if it is persisted in; and I am sorry to say that it is my conviction that these exceptions are far more numerous than is generally believed. It is so easy to make use of a catheter after the first few attempts and it appears to [illegible] for a time, [illegible] for the [illegible] proportion [illegible] however, the results of ordinary catheter life are carefully recorded and the progress noted year by year there is not the least doubt that in the vast majority there is a steady change for the worse; and if candid inquiry is made it is impossible to avoid the conclusion that the downward progress is to a very large extent the direct result of the treatment. Enlargement of the prostate is a progressive disease, though it is curious how very seldom this is realised. Neither the patient nor the gland ever remains stationary. The one steadily grows older and feebler, less and less able to help himself, and the other is always increasing in size. The difficulty grows greater and greater as the ability of the patient to deal with it grows less. Year by year the catheter has to be passed more frequently. At last its use becomes almost incessant day and night. The intervals grow shorter and shorter. The pain becomes almost intolerable. The introduction of the instrument becomes more and more difficult until it may be impossible for the patient and even the surgeon may not find it easy. The bladder entirely loses its power. The habitual passage of a catheter is enough to destroy the contractile power of the bladder within two years. Hæmorrhage becomes more frequent. And far worse than any of these, septic inflammation, due to septic organisms carried in by the catheter, is certain to set in at last. Suppurative cystitis, ascending pyelonephritis, phosphatic calculi, septic prostatitis, thrombosis of the prostatic plexus, periprostatic abscess, epididymitis, and urethritis are some of the commonest consequences of the habitual use of catheters in cases of enlargement of the prostate and are the immediate cause of death sooner or later in the majority of cases that are treated by habitual catheterisation.

It is quite true that these septic troubles ought not to occur and that now that is an accepted fact that inflammation of the bladder is always the result of the introduction of septic organisms (except in the case of specific diseases such as typhoid fever), cystitis is not quite so frequent or so severe as it used to be, but it is absolutely impossible for an old man, growing year by year more feeble and less able to take care of himself, who has to pass an instrument upon himself many times by day and night often at a most urgent call, always, on every occasion, to take adequate precautions. Given abundance of time and assistance the greatest skill will scarcely suffice. With few exceptions the habitual employment of catheters means atony of the bladder and septic cystitis sooner or later; and septic cystitis, with enlargement of the prostate, means at last death by slow torture.

---

[1] The opening paper at the discussion at the meeting of the Harveian Society on Dec. 3rd, 1903.

These are the cases the treatment of which I propose that we should discuss to-day. In actual practice there is no difficulty in finding out which they are; or if there should be a little difficulty in distinguishing them just at first a few weeks' treatment will always show. In case of doubt the catheter should be given a trial first, but if the frequency with which it has to be used increases; if the main feature of the complaint is not so much vesical inability or mechanical obstruction as irritability of the bladder; if the amount of residual urine grows larger; if there is a tendency to cystitis (for undoubtedly patients differ greatly in the degree of their susceptibility to septic organisms); if attacks of congestion are of frequent occurrence; if there is a valve-like outgrowth at the orifice of the bladder or a conspicuous thickening in the posterior median wall of the urethra; if there is any difficulty in the passage of the catheter; if the introduction of the instrument is liable to cause bleeding; if there is a tendency to the formation of calculi in the post-prostatic pouch or if the specific gravity of the urine steadily falls, it is clear that the use of the catheter does not fulfil the necessary conditions and the attempt will end in failure. It may answer for the moment. In the future it certainly will not and the sooner this is recognised and some other method of treatment adopted the better for the patient.

The first essential in the treatment of enlargement of the prostate is to form an accurate opinion as to its nature. It is not sufficient to say merely that the prostate is enlarged or even to describe its shape or size. The cause of the enlargement must be ascertained, whether it is simple congestion of the venous plexuses in and around the neck of the bladder, or actual overgrowth, or the two together in varying proportion. What relation these bear to each other, whether the overgrowth is not, in part at least, the consequence of the prolonged congestion, or whether both are not due to some more remote cause, such as the reflex influence of the testes, is a question of great interest but does not concern us now. We have to deal with the two conditions themselves, usually in combination, and the consequences to which they give rise.

Congestion of the tissues at the neck of the bladder is a much more potent factor (especially in the early days of enlargement of the prostate) in causing the symptoms of which the patient complains than is usually believed. It is the main cause of the early irritability. It greatly increases the susceptibility to inflammation. It weakens the strength of the muscular coat of the bladder by interfering with its blood-supply and at the same time it throws extra work upon the bladder by making it contract more frequently against greater resistance. It may be simply and entirely passive, the result of venous obstruction; or it may be due to the irritation caused by septic organisms or by an excess of uric acid or oxalates in the urine; or it may be reflex, the result of stimuli that originate in connexion with the sexual organs. Not uncommonly all these causes are at workt ogether. Its frequency and the frequency with which it leads to thrombosis of the prostatic plexus may be estimated from the frequency with which hæmorrhage occurs, from the chains of phleboliths which are so rarely absent from the prostatic plexus of old men, and, more than anything else, from the benefit derived in these cases from what is called general or constitutional treatment. I have not to deal to-day with this: I am only concerned with local measures, but I cannot help pointing out that the undoubted value of constitutional treatment depends entirely upon the effect that it has upon this congestion, and in every case in which congestion at the neck of the bladder is a prominent feature constitutional measures, such as rest in bed, hot baths, dieting, and free purgation, must never be omitted. Alone, when the congestion is chiefly passive, they are often sufficient of themselves to give relief, and though unfortunately they are not so beneficial when the congestion depends upon other conditions they are still of great value.

The local treatment of enlargement due to congestion need not detain us long. As a rule local interference with a congested organ tends to make the congestion worse. But there is one method which is not popular because I believe it is not well known but which I have found of great benefit. I allude to Bottini's cautery as modified by Freudenberg. The proceeding is very simple. The bladder is distended with air so as to keep the rest of the wall out of danger and three parallel incisions are made with the white-hot blade of the cautery, one along the floor in the middle line of the neck of the bladder, the others one on each side. An anæsthetic is not necessary if the patient is accustomed to instruments though I think it is advisable. There is very little pain afterwards and I have not met with any case in which the hæmorrhage was worth mentioning. The venous plexuses in the submucous and mucous layers and the nerves, which in this region are so exceedingly sensitive, are divided; and three linear cicatrices are left which contract and distinctly lessen the tendency to subsequent congestion. I cannot recommend this method for enlargement due wholly or even in great measure to overgrowth of the gland. It is inefficient for this and there are other better methods. But in cases in which there are but little growth and much congestion, and in which there is great irritability of the bladder with the imperative necessity for immediate micturition as a prominent feature, and in which the muscular coat of the bladder is beginning to fail, a respite can certainly be obtained, if not a cure, without serious risk. Whether it has any effect in checking the growth I should not like to say but I do not consider that it is probable.

The only other local measure that needs consideration in dealing with prostatic congestion is division of the vasa deferentia or, rather, of the nerves that accompany and surround them. There is no doubt that this operation (and, of course, the other operations that entail the same results upon the nerves coming from the testes) does check to some extent the liability of the prostate to congestive attacks and, so far as these attacks are dependent upon stimuli originating from the testes, it is of some benefit, while it certainly does not expose the patient to any serious degree of risk. As, however, division of the vasa deferentia cannot have any effect upon passive congestion, or upon that which is caused by septic organisms or by irritating substances in the urine, the operation is very often a failure.

The other form of enlargement of the prostate, that which is due to irregular glandular overgrowth, admits only of mechanical treatment. It may lead to obstruction, so that no urine can be passed voluntarily, or it may cause intense irritability of the bladder, according to the direction in which it grows and the amount of congestion that attends it, but whatever it does if palliative measures, such as treatment by catheters, fail, and they nearly always do sooner or later, there is no alternative but removal in some form or other. Drainage can only be regarded as the last resource when the patient is too far gone to stand anything else.

Removal can be effected either by inducing atrophy by means of some operation upon the testes or the spermatic cords or by operating upon the enlargement itself. Of these two methods, the former, like everything else which is novel, was boomed too much and now has met the usual fate by falling into, I cannot help thinking, somewhat undeserved discredit. That it benefited a very large proportion of cases—a proportion, according to American surgeons, as high as 85 per cent.—there can be no doubt; and equally there can be no doubt that it failed sometimes (especially in those cases in which the enlargement was largely due to inflammation) and that it was attended by a much higher rate of mortality than would have been expected from the severity of the operation. Moreover, certain cases were recorded in which very grave mental disturbance, imbecility and even mania, followed the operation; it is even stated that insanity followed the division of one of the vasa deferentia under cocaine, and though I do not believe for a moment myself that the brain and testes in old men are in such close functional relationship with each other as this would imply, the fear of such an occurrence, the strong sentimental objection to the operation, and the success attending removal of the enlargement by operation, all combined, have caused this procedure to fall completely into the background.

An enlarged prostate can be removed more or less completely either through a perineal or a suprapubic opening.

When the bladder is very small and rigid from repeated attacks of cystitis and the prostate is very hard and dense the former method is indicated Under all other conditions the prostate as from the nature of its surroundings it must grow up towards and into the bladder, is best approached through the bladder 14 years ago McGill advocated and performed this operation and though various modifications have been introduced since then it remains in all essential details the same McGill described how the growth was to be enucleated with the finger after dividing the mucous membrane of the bladder and himself enucleated and exhibited both lateral lobes removed in this way In 1892 [2] in the Hunterian Lectures delivered before the Royal College of Surgeons of England I pointed out that "if the operation is to prove successful it resolves itself into removing the whole of the vesical mass, whether it springs from the lateral lobes or is an upgrowth from the posterior wall or is a detached nodule and then extending the exploration down the whole length of the prostatic urethra " and I cited some instances in which the operation had proved, or nearly proved, a failure because the growth had not been followed down the prostatic urethra That was the operation I performed then, following McGill's directions , it is the operation that I have continued to perform since it is the operation that is performed now generally, and it is one that I can thoroughly recommend for these cases A certain amount of confusion, it is true, has been caused by *erroneous description of what has been called* the capsule of the gland But it has been conclusively shown by Shattock and Wallace that the covering on the enucleated masses is a pathological product formed around those masses out of the surrounding tissues by the way in which they press upon them and condense them in their growth The larger and the more lobular the masses of which the enlarged prostate is composed the more easily can they be shelled out because of this fictitious capsule which they form around them , and there can be no doubt that for this form of enlargement this method of operating will not only supersede all others but will do away with the treatment by habitual catheterisation for which these cases are by no means suited Only if the prostate in addition to being enlarged from glandular overgrowth is in a state of intense congestion this must be allowed to subside first under the influence of the constitutional treatment to which I have already alluded and the patient must be warned that if the muscular coat of the bladder has been ruined already by catheterisation and cystitis removal of the enlarged prostate cannot restore it, though it will help it by rendering its work more easy

Wimpole street, W

A CASE OF CHRONIC INTUSSUSCEPTION , EXCISION OF 42 INCHES OF SMALL INTESTINE , RECOVERY[1]

By F C WALLIS B A , M B , B C Cantab ,
F R C S Eng ,

ASSISTANT SURGEON TO CHARING CROSS HOSPITAL, SURGEON TO THE METROPOLITAN HOSPITAL

A healthy looking married woman, aged 32 years was admitted into Charing Cross Hospital on April 14th, 1903 suffering from intestinal colic She was in perfect health until May, 1901 Previously to this she had never had a *day's illness in her life* The bowels *always acted with* great regularity and aperients were rarely necessary She had never suffered from diarrhœa. The present illness began in May, 1901, with a sudden onset of most acute pain in the abdomen (there was no cause for it as far as she knew) The pain was of a colicky character but was not sufficiently bad to make her take to bed until the end of the week when the attacks became more frequent and vomiting commenced Food always excited the colic and vomiting always followed it She described an attack as a "general turning round and round feel in the stomach, followed quickly by vomiting " This attack lasted for three weeks and she was in Guy's Hospital for the latter part of it After this she was perfectly well until August, 1901, when she had a similar attack and there was a third attack in September, 1901 These attacks resembled the first except that the bowels were obstinately constipated for three or four days When the bowels acted she was much relieved and the attack would generally pass off There was no constipation at the beginning of an attack but pain and vomiting preceded it for three or four days. After the third attack she continued well until June, 1902, when there was another attack, since when there had been many milder in degree but all similar in character to the first She had never passed any blood or mucus in the motions The abdomen never became swollen and pressure neither increased nor relieved the pain No tumour had been felt She was admitted into the medical ward of Charing Cross Hospital during one of these attacks of pain and was in for five days, leaving on April 18th, 1903 apparently quite well She was re admitted on April 22nd for another attack of pain during which vomiting was more or less continuous , it was bile-stained but not offensive The abdomen was lax and not tender (this condition existed during all these attacks) On the 25th an indefinite mass was felt below and to the left of the umbilicus

It was decided that unless a distinct improvement took place in the next 24 hours an exploratory laparotomy should be performed As the patient was no better—in fact, getting weak—I operated at 11 A M on the 25th When the patient was under the anæsthetic a large freely moveable mass could be felt in the left umbilical region The abdomen was opened in the mid line below the umbilicus by an incision which was lengthened to five inches in all The palpable mass was an intussusception involving small intestine only The length of bowel involved amounted to three feet six inches The proximal gut was materially distended An unsuccessful attempt was made to reduce the invagination and enterectomy was decided upon Whilst lifting the involved gut out of the abdomen the distal end tore like a piece of wet blotting paper close to the end of the intussusception and it was noticed that this part of the bowel was much inflamed The intestinal contents were expressed at either end and Lane's intestinal clamps were applied on healthy bowel The bowel was divided first at the upper end and the mesentery was cut through parallel to the intestine, the vessels being clamped as they were cut The intestine was divided at the lower end and the two ends were united with a Murphy's button A few Lembert sutures were put in in addition and the cut edges of the mesentery were sewn together with silk sutures, the vessels being ligatured with silk also Some hæmorrhage found its way between the layers of the mesentery The parietal wound was closed by one row of separate fishing-gut sutures The operation lasted for one hour The patient stood it very well and her pulse was 120 at the end One pint of beef tea was given by the rectum There was practically no shock from the operation

The patient was nourished by rectal enemata only for two days , on the third day small quantities of plasmon and thick barley water were given by the mouth and on this day the bowels acted twice the motions being well formed The food by the mouth was gradually increased and the rectal feeding was discontinued, the stitches were removed on the eighth day, and everything went very well indeed until May 15th (three weeks after the operation) when the patient had an attack of pain similar to those she had previously suffered from paroxysmal colic with intervals free from pain Chloroform was administered and on palpating the abdomen I could feel the button in what I thought was the descending *colon It was quite easily pushed down into the* pelvis but it could not be reached by the rectum No button was passed and the pains continued. On May 18th the button was seen by the x rays to lie on the outer side of the right rectus two inches above the inlet of the pelvis On the 19th I reopened the abdomen and found the button about four inches above the ileo cæcal valve , it could not be passed on into the colon so I removed the button through a longitudinal incision which was sewn up transversely From this second operation the patient made a perfect recovery and left the hospital quite well on June 10th I saw her recently and she was in the best of health

The following is the pathologist's description of the specimen 'No 1223 Enteric intussusception in adult 42 inches of small gut *excised* A portion of small intestine, 67 centimetres (26½ inches) of which forms the outer coat (intussuscipiens) of an intussusception which has been greatly reduced, a double layer 18 centimetres (seven and a quarter inches) now remaining invaginated. The apex of the intussusceptum shows considerable reddening and is thickened from inflammation and œdema. The returning sheath is greatly thickened. The indrawing of the mesentery sheath is well shown. The outer coat is considerably dilated and somewhat irregularly thickened. Here and there congested vessels may be seen. Eight centimetres (three inches) from the lower end is an oval opening two centimetres in diameter which seems to have been torn as its edges are irregular; microscopically the gut near the orifice is in parts quite healthy, in others swollen and infiltrated with round cells."

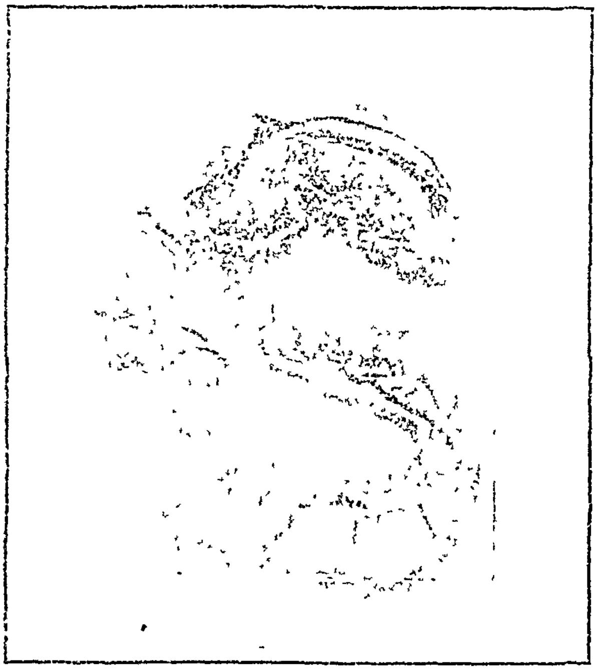
[2] The Lancet June 4th (p 1223) 11th (p 1287) and 18th (p. 1354) 1892

[1] A paper read before the Clinical Society of London on Nov 27th 1903



Intussuscepted portion of gut removed.

When the intussusception was first exposed and before the mesentary was divided the apex of the intussuscepted part was close up to the inflamed part of intestine which tore apart when the intestine was lifted out of the abdomen—but after removing the intestine the intussusception slid back to its present position, although when *in situ* it was quite impossible to reduce it in the slightest degree.

The *contretemps* with the Murphy's button was unfortunate It is the only time that I have ever had any trouble and I have used these buttons now in a large number of cases. It was due to the fact that I put in a button somewhat larger than the size generally used for small intestine. My reason for doing so was that the proximal end of the intestine was considerably distended and the slightly larger button made approximation easier. It did not occur to me at the time that there would be any difficulty in the passing of the button and ordinarily speaking I do not think that there would be any difficulty in its passage. In an urgent operation of this magnitude time was of the greatest consequence and I do not know any other means by which the two ends of the intestine could be so rapidly and securely brought together. The main part of the time taken (one hour) was spent in cleaning the skin of the abdomen, removing the intestine, tying a large number of vessels, and uniting the widely separated ends of the mesentery. The sewing in and clamping of the two ends of the button did not take more than five minutes.

Why the gut should have torn in the way it did was a matter of some speculation and a microscopical examination of the torn edge showed only inflammatory infiltration. I believe the softening of the intestine here was due to interference in the blood-supply and there is no doubt that perforation would have occurred at this spot very soon.

As to the cause of the intussusception there is nothing to show that it was due to anything but an irregular action in the muscular wall of the intestine. Cases of chronic intussusception are not uncommon but one such as this is, I think, worth recording. The points of interest are: (1) the length of time (over two years) which it lasted; (2) the excellent health of the woman between the attacks and, I am glad to say, since the operation; (3) the large amount of small intestine involved (most cases of chronic intussusception have to do with the large intestine); (4) the fact that no tumour was felt with any certainty until the patient was anæsthetised; and (5) there was no exciting cause such as growth, tumour, or ulceration which is commonly the starting point in cases of chronic intussusception.

Harley-street, W.

ADAPTATION AND COMPENSATION.[1]

BY G. A. GIBSON, M.D., D.SC., F.R.C.P. EDIN.,

PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH.

THE title which has been chosen for this communication may savour of diffuseness and it might have been better to qualify it in some way so as to denote its meaning more definitely. My intention is primarily to bring before the society some illustrations of adaptation and compensation and although certain generalisations will be inevitable, yet in so far as possible it will be my aim to avoid them. The choice of the subject has been somewhat fortuitous. When making a fresh study last winter of acromegaly and gigantism some very interesting appearances, only to be explained by compensatory processes, forced themselves upon my attention and turned my thoughts strongly in this direction—a direction in which a great deal of my previous work has lain. When looking about for some theme that might prove interesting to the society it therefore naturally occurred to me that the subject might not unprofitably occupy us during part of this evening.

Let me, by way of preface, bring out very shortly one or two points in regard to the adaptations which may be seen in acromegaly. The accompanying illustrations demonstrate in the most graphic fashion the enormous increase which occurs in the lower part of the face, and more particularly in the inferior maxilla. This is shown in the photographs taken from life, but the most interesting points are to be ascertained from the skulls of such patients after death. In the beautiful photographs reproduced in Figs. 1 and 2, kindly furnished by Professor D. J. Cunningham of Edinburgh, the enormous preponderance of the lower maxilla is clearly shown and a photograph of the vertex of the skull (Fig. 3) shows that the temporal ridge has risen greatly towards the vertex. Similarly, in Figs. 4 and 5, for which my thanks are due to Professor A. F. Dixon of Dublin, the huge size of the lower jaw is well shown, and in Fig. 6 the temporal ridge is even more distinctly brought out than in the other skull as vastly increased. Now there is only one possible explanation for these appearances. In consequence of the increased weight of the jaw the temporal muscle has more work to perform and it has therefore undergone hypertrophy. That this is the truth may easily be ascertained by comparing the head of a young child with that of acromegaly and it is still further proved when such a skull is contrasted even with the highest of the anthropoid apes, in which there is a direct ratio between the heavy jaw and the large temporal muscle.

In another direction most marvellous adaptations are to be found when we study congenital affections of the heart. The consideration of the changes which occur at the period of birth would prepare us for wonderful possibilities of adaptation. Let me, by way of example, cite one interesting fact which has been emphasised by Gérard.[2] Up to the moment of birth the diameter of the ductus arteriosus exceeds that of the pulmonary arteries, the difference, according to him, varying by one, two, or even five millimetres. By the eighth day the arterial duct is practically closed and the pulmonary arteries have rapidly increased to a diameter much exceeding that of the closed or closing duct. In the case of cardiac malformations we have a most fertile field for the investigation of possibilities of modification and it is found that the adaptation is such as will compensate for defect without surpassing it. This has been very vividly brought before me recently in a most interesting example of congenital affection of the heart which occurred in the wards of my colleague, Dr. A. James, to whose kindness I am indebted for permission to refer to the subject and to show a picture of the heart (Fig. 7). It was an instance of one of the rarer malformations. The undefended space between the two ventricles was patent; the pulmonary artery was represented by a narrow band of fibrous tissue and the aorta supplied the right and left pulmonary arteries as well as its own proper branches. Notwithstanding these defects the patient, a boy, had lived to the age of 16 years. The heart showed a most beautiful retention of embryonic conditions as regards the musculature of the ventricles. They were as nearly as possible of equal thickness, the right, however, being slightly in excess of the left. The exact measurements were as follows: left ventricle, 17 millimetres; right ventricle, 19 millimetres; or respectively $\frac{11}{16}$ths and $\frac{12}{16}$ths of an inch. The reason for this is very obvious. Both ventricles had to overcome the same pressure and their thickness was therefore approximately identical. In well-marked contrast to this let me mention that in cases of permanency of the ductus arteriosus, where the channel of communication is, as it usually is, small, there is but little increase in the thickness of the right ventricle. The rise of pressure in the pulmonary artery being but slight there is little cause for any hypertrophy of the right ventricle. Assuredly this is an exquisite example of adaptation. Reference has been made to embryonic conditions. During ante-natal existence, when, in consequence of the arrangements then existing, both ventricles are exposed to almost similar pressure, the thickness of the ventricles is found to be practically equal. This is a subject which some years ago engaged my attention [3] and it may be well, by way of clinching the argument,

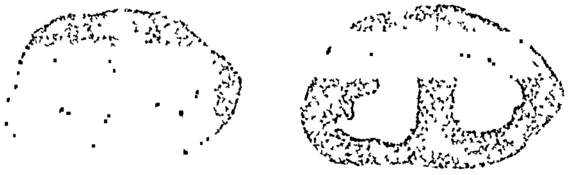
to show some sections of these fœtal hearts, two of which are reproduced in Fig. 8 In these the ventricular walls are of almost the same thickness. Such are a few outstanding subjects which have led my thoughts of late to run in the direction indicated by the title of this paper; they are only given by way of preface. My real object is to bring before the society certain modifications in the constituents of the blood, in the structure of the arteries, and in the condition of the heart which can only, it seems to me, be explained upon similar grounds.

FIG. 8.



Two sections of a fœtal heart in the fifth month, showing almost equal thickness of the two ventricles.

In requesting your attention for a few minutes to some changes in the blood let me begin my observations with the remark that in what follows no special reference will be made to any alterations in the white blood corpuscles. Firmly believing in the great doctrine of phagocytosis as one of the most important explanations of immunity, and accustomed to seek and to find its appearances in numerous cases of disease, it is nevertheless no part of my intention this evening to deal with it in any of its bearings. The complexity and uncertainty still hovering around the leucocytes must necessarily render any attempt to summarise their functions at present extremely difficult.

When we turn from the leucocytes to the erythrocytes we are on more certain ground. A considerable amount of accurate information is now available as regards the life history of the red blood corpuscles, and this is more particularly the case in respect of the duration of their existence and their final destiny. The investigations of Quincke[4] and Hunter[5] have cleared up many points of uncertainty on such subjects and it would be most interesting to refer to them if time permitted. We must, however, proceed to our more immediate subject. An increase in the number of the erythrocytes beyond their normal is exceedingly common in many disturbances of the circulatory and respiratory apparatus. In fact, it may be stated that any interference with the oxygenating function is followed by more or less cyanosis, usually along with hyperglobulism. The amount of increase in the erythrocytes bears a more or less definite ratio to the extent of the disturbance of oxygenation. In cases of cyanosis from many causes such changes have engaged my attention To summarise the conditions let me shortly state that in cyanosis the blood is of high specific gravity, often reaching 1075. The amount of hæmoglobin is considerably increased, commonly reaching such a figure as 120 per cent. The erythrocytes are often above 7,500,000, and the leucocytes, although not so commonly altered in number, not infrequently exceed 12,000. It is interesting to observe that the hæmoglobin index is almost invariably reduced. Let me here show you some photographs of the blood counts in such diverse conditions as pernicious anæmia (Fig. 9), perfect health (Fig. 10), and considerable cyanosis (Fig. 11), all in equal dilution—1 in 200. Many of these facts have been known for the last 20 years, since their first observation by Toeniessen.[6] Some years ago, frequent observation of these phenomena led me to suggest that the increase in the red corpuscles, as well as in the hæmoglobin, may be regarded as compensatory[7] As such a conception can hardly be regarded in itself as explanatory, the consideration of the subject induced me to propose the hypothesis that from insufficient oxygenation the erythrocytes are not called upon to perform such active functions as in health and that, their functions being lessened, or, in other words, their tear and wear being reduced, the duration of their individual existence is increased. The number of the corpuscles may be expected in this way to be augmented until an equilibrium is produced between their production and destruction. In some later remarks upon this subject[8] it was candidly allowed that this hypothesis could only be seriously considered if the increase in the blood elements were proved to exist throughout the different divisions of the circulatory mechanism, arteries, capillaries, and veins.

Since the date of these earlier investigations abundant opportunity has been afforded me of further observations upon the subject and on several occasions it has been in my power to compare the condition of the blood in cyanosis as it occurs in arteries, capillaries, and veins. A number of the results were recently published[9] and from them you will allow me to choose one of the most striking instances.

A boy, aged 16 years, was lately under treatment in my wards for a group of symptoms which could only be explained by the diagnosis of mediastinal pericarditis. On admission in September, 1902, the boy was deeply cyanosed. His heart was but slightly enlarged and had no abnormal sounds. The pulse was of low pressure and manifested in the most distinct manner the features of the pulsus paradoxus. The patient had enormous enlargement of the liver and considerable increase in the size of the spleen, along with hydrothorax, ascites, anasarca, and albuminuria. The subcutaneous blood was frequently and regularly examined and showed an amount of hæmoglobin varying between 80 and 100 per cent., while the number of red corpuscles fluctuated between 8 000,000 and 8 800.000 per cubic millimetre and the number of white corpuscles oscillated between 5000 and 8500 per cubic millimetre. On Oct. 20th a drop of blood was obtained from a small twig of the temporal artery and another from a small tributary of the temporal vein in order to compare with the blood in the capillaries; the following results were obtained. Artery: hæmoglobin, 93 per cent.; erythrocytes, 7,000,000 per cubic millimetre; and leucocytes, 6875 per cubic millimetre Capillary: hæmoglobin, 93 per cent.; erythrocytes, 8,500,000 per cubic millimetre; and leucocytes, 8500 per cubic millimetre Vein: hæmoglobin, 115 per cent.; erythrocytes, 10,000,000; and leucocytes, 7400 per cubic millimetre.

In such a case as this it is extremely interesting to notice the general but not uniform increase, both in the number of erythrocytes and in the amount of hæmoglobin. It must be obvious that such an increase cannot be due to a simple blocking or backward pressure, as there would then be a very much greater difference between the numbers in the arteries and in the veins than at present exists. The difference, such as it is, may be accounted for by the transudation of fluid from the blood-vessels into the lymph vessels, which ought undoubtedly to exercise some influence in increasing the density of the blood returning in the venous system. The conclusion seems unavoidable that in such an instance as this there is an attempt on the part of nature to compensate for deficient aeration by an increase in the oxygen-carrying tissues. A consideration of the condition of the blood in pernicious anæmia strengthens me in this idea. Agreeing in the main with the theory of Hunter[10] as to the pathology of this disease my opinion coincides with the views of Laache[11] that in the increased amount of hæmoglobin in the individual erythrocytes nature is attempting to adapt herself to changed conditions and to compensate for the destruction of the blood corpuscles. These views have received the enthusiastic support of Hamilton and other pathologists. In a recent letter from Professor Hamilton[12] he writes as follows: "The efforts made at compensation in pernicious anæmia evidently point to a very delicate mechanism for keeping up the number of oxygen bearers."

The modifications in the amount of hæmoglobin and in the number of corpuscles at high altitudes are undoubtedly compensatory. It has been shown by many observers and more particularly by Bard and Curtillet[13] Viault,[14] Grawitz,[15]

Zuntz,[16] Vaquez,[17] and Mercier[18] that there is a distinct ratio between the number of the corpuscles and the height above the sea level at which the individual resides. The following table, given by Marie,[19] may be taken as a brief summary of the facts:—

—	Metres above sea.	Number of erythrocytes.
Christiania	0	4,970,000
Göttingen	148	5,225,000
Tubingen	314	5,322,000
Zurich	412	5,752,000
Görbersdorf	461	5,800,000
Reiboldsgrun	700	5,970,000
Arosa	1800	7,000,000
Cordilleras	4382	8,000,000

It has been generally considered that, with diminished atmospheric pressure, the interchange between the oxygen of the air and the blood corpuscles would be diminished and that in consequence the latter would adapt themselves to circumstances and increase in number by way of compensation. Quite recently, however, we have seen an instance of what Huxley[20] calls "the great tragedy of science—the slaying of a beautiful hypothesis by an ugly fact." In a paper lately published by Weinzirl[21] he has called in question these generally accepted statements and has asserted that the increase in the erythrocytes due to altitude is only temporary. Weinzirl has carried out some observations upon blood counts of rabbits at two different altitudes, one of 5000 and the other of 7000 feet above sea level, the general result of which is to show that while the rabbits after being kept in a warm atmosphere for some time underwent an increase in the red corpuscles on being transferred to a colder atmosphere at the same level, they lost a certain proportion of the erythrocytes on being moved up to the higher level. Such were the general results in six different animals, in only one of which was there an increase in the erythrocytes at a higher altitude. These results are at variance with all previous observations and they must be carefully repeated. That cold is an important factor in accounting for the blood changes at high altitudes cannot be doubted, and the comparative table of blood counts in summer and winter seasons which accompanies Weinzirl's paper strongly supports his contention as regards the influence of temperature.

Another set of phenomena, quite recently disclosed by the investigations of Vaquez,[22] Cabot,[23] McKeen,[24] Saundby and Russell,[25] and Osler,[26] must give us pause in our consideration of polycythæmia. These different observers have brought before us a series of cases of cyanosis which they assert to be of unknown origin. In every case the spleen was enlarged and in every case but that of Vaquez there was albuminuria. In most of the cases it is specifically stated that there was no cardiac affection, but in the case described by Saundby and Russell there was found to be a hypertrophy of the left ventricle on post-mortem examination, while in the case under the care of Dr. Stockton of Buffalo, which is given by Osler, it is mentioned that the full report of the post-mortem examination is not yet available, but that Dr. Lyon states the heart to have been about normal. The first thing which strikes the candid reader about these cases is that they were all of middle age, the youngest being 35 years and the oldest 53 years. All the rest were between 40 and 50 years of age. In the next place, every patient had albuminuria, with one possible exception, and a considerable proportion of the patients had noteworthy changes in blood pressure. It is not to be overlooked that we have no record of any microscopic examination of the heart muscle such as would be required before we can accept the statement that the hearts in these patients were normal. Careful consideration of the records of these cases has led me to the conclusion that it is highly probable they were instances of myocardial weakness. Many patients with symptoms closely resembling those described have been under my care, but in every one of them the conclusion was forced upon me that the cyanosis, enlarged spleen, and other appearances were secondary to the myocardial weakness, and in some of them the diagnosis was verified after death. Until further light has been thrown on the complex of symptoms described by the observers just mentioned we must suspend our judgment, but it seems to me that the blood changes are probably compensatory, the result of cardiac debility. This belief, indeed, appears to be somewhat similar to that held by Cabot[27] who writes as follows: "I do not believe that we are here dealing with a genuine plethora but with a venous congestion, the cause of which, however, remains a mystery."

Let us now turn, in the next place, to some illustrations of our theme as manifested by the vessels. It appears to be the general belief that the changes in the arteries are very largely to be summed up in a change of structure commonly known as sclerosis. That this is not the whole truth has, however, been often suspected and even Thoma, who may be regarded as the high priest of the cult, admits that there are other changes than a mere increase of fibrous tissue. He states, for example[28]: "Bei Zunahme der Wandspannung der Arterien nimmt, wie bereits früher berührt wurde und wie ich an einem anderen Orte genauer nachwies, die Tunica media an Dicke zu." All the vessels throughout the body are, in virtue of their contractile structure, endowed with the faculty of adapting themselves to their contents. Such changes are not merely to be observed in the arteries but also in the veins. In Raynaud's disease certain very interesting phenomena of this kind are to be observed. Barlow[29] has mentioned a moniliform or beaded appearance in the superficial veins in this disease and in one most interesting example, a young man who was in my own wards during the present year, the whole of the superficial veins of the body stood out like so many lengths of whipcord during the phase of spasm. That this takes place in the arteries is frankly admitted by everyone, and Russell[30] has called attention to the condition of exaggerated contraction, for which he has adopted the term "hypertonus." Of the existence of such frequent and prolonged increase of arterial spasm there can be no possible doubt. It may be produced by many different conditions, such as nervous influences and toxic states, into which it is impossible for me at present to enter.

The main point for us to consider is whether, in consequence of the altered lumen brought about by the hypertonic condition, there is any alteration in structure—such is the question which we must answer. Now, Savill some years ago brought before the British Medical Association some most interesting observations[31] upon this subject. He described the great increase in the thickness of the tunica media for which he introduced the term "arterial hypermyotrophy." His investigations have, since the appearance of that earlier paper, been much extended and have thrown much light on a difficult and obscure subject.[32] He is undoubtedly justified in regarding such facts as affording a beautiful illustration of adaptation and compensation. Russell is certainly right in his statement that a condition of excessive contraction may occur in arteries which are perfectly healthy, as well as in those which are apparently in a state of sclerosis. Admitting that *this does* take place, his further contention must be allowed that the idea of muscular degeneration and consequent inability on the part of the vessels to contract in adequate response to nerve or blood influences must be materially modified. The effect of such repeated and persistent contraction of the blood-vessels ought certainly to be an increase in the muscular coat of the arteries and this is what *does* occur. In the illustrations now brought before you this hypertrophy may be seen. Fig. 12 shows great increase in the tunica media, with little change in the intima; Fig. 13 has more thickening of the latter. In asserting that such conditions of hypertrophy of the tunica media do take place, it is far from my intention to hold that it is the only vascular change. A truly sclerotic condition is extremely common, and this, too, in several different varieties. Such a change in the blood-vessels is undoubtedly produced by an increased growth of fibrous tissue. As stated by Thoma,[33] the alterations are as follows: diminution of elasticity, dilatation of vessel, and retardation of current, which last is the cause of a new formation of fibrous tissue in the intima.

An observer to whom we owe much as regards the investigation of these questions is Mott,[34] according to whom the vascular condition consists in "a local or general thickening of the arterial wall with loss of elasticity, occasioned mainly by fibrous overgrowth of the tunica intima, secondary and proportional to weakening of the muscular and elastic elements of the media." Into the points of relationship between a previous weakening of certain of the arterial coats and this compensatory overgrowth—the fibrous tissue—it is foreign to my purpose to enter, but it may not be out of place for me to express the view that while a hypertrophied condition of the media and a sclerotic condition of the intima may, and probably do, arise from intoxication, the nutrition in the former case must be better than in the latter and thus allow of the possibility of hypertrophy. Facts are not sufficient as yet to allow of any generalisations, but from many observations it seems to me that the vasa vasorum are in some way intimately connected with these two different processes. To this relationship between nutrition and fibrosis we must briefly advert when considering some of the changes in the heart now about to be referred to.

The last concrete examples to be brought before you belong to cardiac pathology. As is well known, when from any cause—and the factors universally recognised are legion—there is any necessity for increased exertion along with an adequate supply of nourishment the heart undergoes hypertrophy. The converse condition, atrophy, arises when from failing energy there is less demand for exertion and from waning nutrition there is less food for the heart. There are many questions still unanswered in regard to hypertrophy. The teaching of Cohnheim[35] that there is a primary or idiopathic hypertrophy is still sometimes echoed in the present time, but it is probable that there is no serious supporter of his views. In all the examples cited by Cohnheim there is, on careful investigation, found to be an increased amount of work, whether arising, as in exophthalmic goitre, from greater frequency of the heart, or, as in the instance of the beer-heart of South Germany, from an excessive quantity of fluid that has to be driven through the tissues as well as an augmented supply of food for the heart. It is certainly not going too far to assert that primary or idiopathic hypertrophy of the heart in the strict sense of the phrase is absolutely mythical.

Another point arising is connected with the mode of increase in the affected organ. Does it increase by an enlargement of the individual fibres or by an augmentation in the number of these fibres? Here the answer must be in the affirmative to both questions. And yet the absolute proof is somewhat difficult. The size of the different fibres in a healthy heart is exceedingly variable. This may be seen by comparison of Figs. 14 and 15, which are taken from two parts of the left ventricle of the same heart situated very near to one another. That there is an increase in the size of the individual fibres in hypertrophy is beyond doubt, and in Fig. 16 a fibre of great size is shown. On the other hand, a numerical increase, such as must occur in the gravid uterus, for instance, would certainly be expected in the hypertrophied heart, and the careful measurements of Zielonke[36] have rendered this to my mind absolutely unassailable. Yet it must be obvious that without the exercise of a patience as remarkable as rare this belief could hardly be affirmed to have reached the stage of proof. Is it possible that the different appearances observed vary according to the age of the individual in whom they occur and that we have here an illustration of the principle so clearly stated by Moore[37] in his recent paper on unsymmetrical kidney? According to his view the younger the individual the greater the increase in the number of the fibres—the older the individual the greater the increase in their size. Such is the meaning of his enunciation of "a general biological principle—viz., that a persistent demand for increased functional activity made on any structure during its developmental stage is met by a corresponding increase in the production of the functioning elements, whilst such happening after the cessation of development is met by an increase in the size of the individual elements." That this is not to be asserted without some reservation is, however, clear from a comparison of sections of the two ventricles in the case of congenital heart disease formerly referred to. In the right ventricle (Fig. 17) the fibres are decidedly larger than in the left (Fig. 18). Yet this hypertrophy must have commenced at an early period; we may indeed say that the embryonic condition persisted, with an equal growth of either ventricle.

It is very commonly held that when hypertrophy has reached a certain degree degeneration must infallibly follow. In this statement there is a certain amount of truth—just enough of truth to render it of dangerous plausibility. It has been asserted that when a certain stage is reached the hypertrophied heart is liable to fatty degeneration. This contention, which obtained the sanction of Cohnheim,[38] is, as Hamilton[39] observes, "a vast exaggeration." Abundant observation has convinced me that the assertion deserves to be condemned to the realms of oblivion. The hypertrophied heart is, as a rule, of healthy appearance, and on microscopical examination it does not show a trace of fatty degeneration. Only in hearts which have outlived their possibilities of nutrition and are undergoing dissolution is any fatty change to be seen.

While such are the facts as regards a supposed fatty metamorphosis in the hypertrophied heart it is far otherwise as regards the association of the process of hypertrophy with chronic interstitial myocarditis, or fibroid degeneration, as it is often called, of which several different stages were described and illustrated by me in a lecture delivered before the Medical Graduates' College.[40] When the supply of blood generally or locally is insufficient a chronic fibroid invasion takes place and this may or may not be an attendant on hypertrophy. This has been repeatedly shown by many authors and the fact, now thoroughly recognised, has again been lately investigated by Cowan.[41] The common appearances may be observed in Fig. 19, where a very great amount of increase of fibrous tissue is to be seen. But the new growth of fibrous tissue may greatly exceed such more ordinary appearances and in Fig. 20 an excessive degree of interstitial myocarditis may be observed. May we not in this see an example of the "law of parsimony"? While illustrating the "law of economy" in his eloquent address in the Physiological Section of the British Medical Association at the Oxford meeting of 1868 Rolleston[42] remarked: "Where by the employment, as in what is called 'histological substitution,' of a lowly organised or vitalised tissue, such as elastic tissue, she can spare herself the manufacture of such expensive structures as muscle, there nature adopts a line of practice which we call a law of parsimony." This principle, although primarily intended in elucidation of biological processes, is obviously of application to the r [illegible]

It seems to me that [illegible] be drawn between the arterial [illegible] ave been brought before you to-night. In one set of circumstances, with overwork but adequate nutrition, the arterial, like the cardiac, muscle fibres become enormously increased. In a different combination of conditions, in which increased work, along with indifferent nutrition or toxic states, takes place, the arterial walls, like the cardiac, undergo sclerosis. That this is preceded by dilatation of the lumen of the artery, as Thoma[43] believes, is as destitute of proof as would be the analogous statement that a dilatation of the heart is an invariable precursor of fibroid degeneration. Conversely, when less work is demanded of the heart it undergoes simple atrophy. Many such instances cross the path of the pathological observer in different states of lessened demand. When along with such diminution of work there is at the same time interference with nutrition the condition of pigmentary atrophy is the common result. To this latter it would be foreign to this paper to allude, but of the former illustrations are to be found in Figs. 19 and 20.

---

[37] *Journal of Anatomy and Physiology*, London, 1903, vol. xxxviii, p. 99.

[38] Op cit., p. 47.

A few general remarks upon hypertrophy may fitly conclude these observations. It is held by some observers, and particularly by Thoma,[44] that a hypertrophy may take place which is not functional in its origin. He cites in proof of this the fact that if one ovary or testis is removed in extreme youth the other undergoes an increase in size. Inasmuch as certain of the great functions of these organs have not begun to manifest themselves at such an early period he seems to regard them as inactive. Surely this is an extremely narrow view of the matter. From what we know of the glands it seems clear that each one of them produces an internal secretion which is of specific importance as regards the well-being of the whole body. It is more than probable, nay, it is absolutely certain, that the ovary or testis is intimately concerned with the development of the sexual characteristics from the earliest period. Until comparatively recent times it used to be held that the sexual manifestations were not revealed until the time of puberty. This belief has now been shown to be erroneous, and the fact—now abundantly proved by the observations of Fehling,[45] Thomson,[46] and Merkel[47]—is that from an early period of fœtal life even the form of the pelvis is diverse in the two sexes.

Another important consideration strengthens me in the conception that hypertrophy of a non-functional origin is erroneous. Bradford[48] in his interesting Goulstonian lectures raised some important questions as to whether the remarkable results following excision of a portion of the kidney are due to compensatory growth or to other causes, and Murray[49] in the following series of lectures under the same foundation tried to answer the question with special reference to the thyroid gland. As his remarks are as succinct as they are lucid the best method of reference to them will be to quote them entirely. "If the compensating growth of the one lobe takes place simply in response to a call for more secretion to make good the loss of the other lobe no hypertrophy should take place if this want is fully supplied from other sources. This point may be tested by removing one lobe of the gland and giving thyroid secretion continuously for some time and then removing the other lobe for examination. If no changes indicating compensatory hypertrophy are found in the second lobe it goes far to show that the hypertrophy develops simply as the result of an insufficient amount of thyroid secretion being present in the blood. To test this point the right lobe and parathyroid were removed from a male bonnet monkey. For the next three weeks 12 minims of thyroid extract were given in the course of each week. Then as the animal became rather emaciated the quantity was reduced to half this amount for the next five weeks. Slight myxœdematous symptoms then appeared but they diminished on increasing the dose to 24 minims in the week; this was continued for two and a half weeks, when the animal died from dysentery. The left lobe was found to be pale in colour and only weighed 0·03 gramme. No parathyroid was found attached to it. Microscopical sections showed no signs of compensating hypertrophy even in its earliest stages. In another experiment the right lobe and parathyroid were removed and one minim per diem of thyroid extract was given by the mouth for 16 weeks and then the left lobe and parathyroid were removed. The right lobe with the parathyroid which was removed first weighed 0·3 gramme and was found to be abnormal in structure to start with, as it resembled a hypertrophied gland in structure. Similar appearances were found by Halsted in the thyroid gland of several healthy dogs. The occasional occurrence of such changes in apparently healthy animals is at present difficult to explain. The interesting point in this case is that after the prolonged interval of 16 weeks during which the extract was given the left lobe was found to be paler in colour and it weighed 0 25 gramme The microscopical structure was normal and showed no signs of commencing compensatory hypertrophy. If this lobe was originally in the same condition as the right the treatment seems to have restored it to a normal condition and if not it at any rate showed no signs of compensating hypertrophy. As far as they go these experiments tend to show that if the proper amount of secretion is supplied after the removal of one lobe compensating changes do not take place in the other."

One more instance before concluding. In the philosophic remarks by John Thomson on defective coördination in utero as a probable factor in the production of congenital malformations he gives his opinion[50] against the occurrence of primary hypertrophy. In this thoughtful paper he states: "There are only two conditions that I can think of under which muscular hypertrophy seems to occur without antecedent overwork—namely, (*a*) the extraordinary hypertrophy of the uterus which takes place during pregnancy; and (*b*) congenital giantism, local or general, such as occurs in congenital hemi-hypertrophy." These, however, are really not examples of hypertrophy without antecedent overwork: the walls of the uterus, assuredly, during pregnancy undergo an enormous amount of overwork in resisting the stress of embryonic development, and any hypertrophy of muscles in conditions of giantism is in direct ratio to the increase of the structures upon which the muscles exert their force. The consideration of all these interesting results confirms me in the belief that a supposed non-functional hypertrophy is a baseless figment of the imagination.

It is a pleasant duty to express my thanks to Dr. T. Shennan of Edinburgh and Dr. J. M. Cowan of Glasgow f[illegible] ready help in the preparation of this paper and also acknowledge my obligations to Mr. Richard Muir of [illegible] University pathological department and to Mr. W[illegible] Watson of the laboratory of the Royal College of [illegible] for constant assistance in photographing the [illegible] employed in the work.

Edinburgh.

A CASE OF INVASION OF THE CAUDA EQUINA BY TUMOUR WITH DEMARCATION OF ALL THE SENSORY ROOT AREAS OF THE LOWER LIMBS.

By CHARLES R. BOX, M.D. LOND.,
ASSISTANT PHYSICIAN TO ST. THOMAS'S HOSPITAL AND TO THE LONDON FEVER HOSPITAL; LECTURER ON APPLIED ANATOMY, ST. THOMAS'S HOSPITAL.

THE case here recorded is one which as resident assistant physician at St. Thomas's Hospital I had under daily observation for a period of nearly eight months and I was able to make a complete series of charts illustrating the progressive affection of sensation in the lower limbs. By the courtesy of Dr. J. F. Payne and Dr. H. W. G. Mackenzie, in whose ward the patient lay, I am able to publish the full details of the case which appears to be of exceptional interest in that it affords distinct evidence of the arrangement of all the sensory root areas which belong to the cauda equina.

The patient, a lad, aged 13 years, was admitted to St. Thomas's Hospital on Dec. 29th, 1899 He was transferred to an infirmary on August 18th, 1900. where he died a few weeks later. No necropsy was obtained. The boy was one of a family of 13 children, all of whom were living His parents were healthy and there was neither history nor evidence of syphilis in the family. The paternal grandfather was alcoholic and died from phthisis. The patient had chicken pox and measles before he was three years old but since then had always been a healthy, active, and intelligent boy. He was in the sixth standard at school. His mother dated the commencement of his illness from a visit to the swimming baths two months before his admission to hospital. At all events shortly after this he began to complain of inability to sit or to lie comfortably on account of pain in the lower part of his back. This pain gradually increased and for ten days before admission he had been screaming night and day and absolutely unable to sleep. The intensity

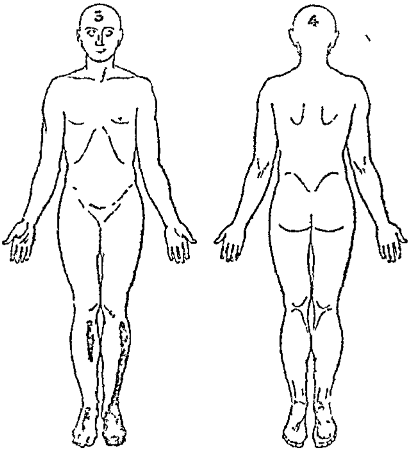
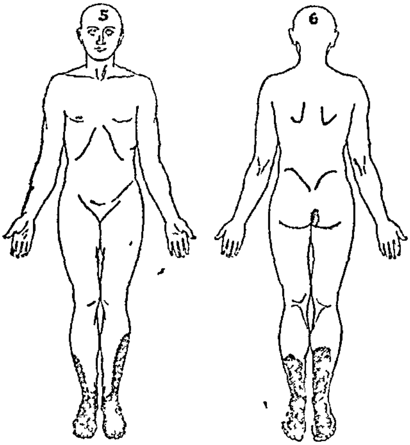
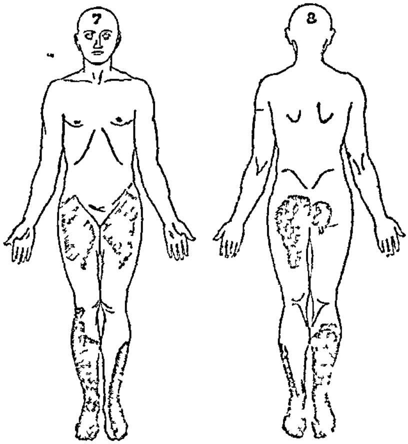
Jan. 2nd. The cremasteric reflexes were present 1 and 2 L * The knee-jerks were absent, 3 and 4 L The plantar reflexes were absent but common sensation was present in the soles, 1 and 2 S The muscles were wasting, especially the calves, 1 S.



Jan 9th The exact extent of the motor paralysis was doubtful There were no knee jerks and no plantar reflexes The right cremasteric reflex was absent 1 and 2 L Retention of the urine persisted for several days 11 and 12 D and 1 L *(detrusor vesicæ)* There was *occasional incontinence of* the fæces ? 4 S The sensory areas on the left side were 5 L and part of 1 S



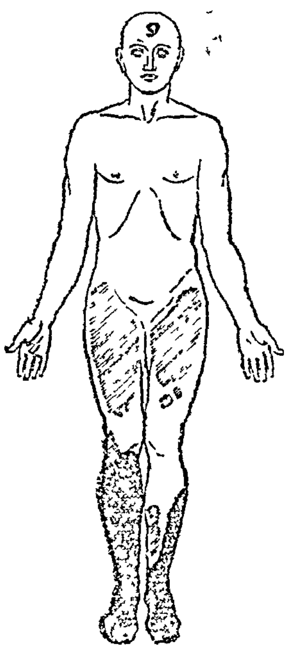
Jan 12th Motor paralysis, by faradism, from 3 L to 2 S *on the right and from 5 L to 2 S on the left The reflexes* were as before The sensory areas 5 L with indications of 1 S and 5 S



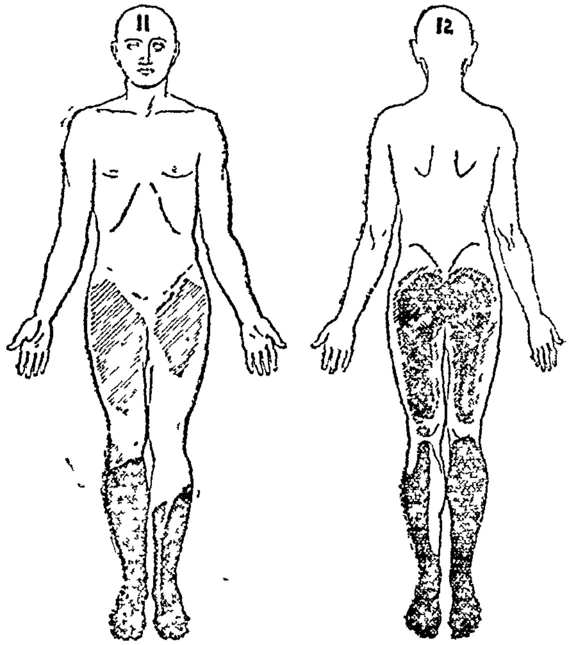
Jan 13th Motion and reflexes were as before. Sensory areas right side 4 and 5 L 1 and 5 S with indications of others, left side, 5 L, with 1, 5, and 4 S

* L = lumbar; D = dorsal, S = sacral

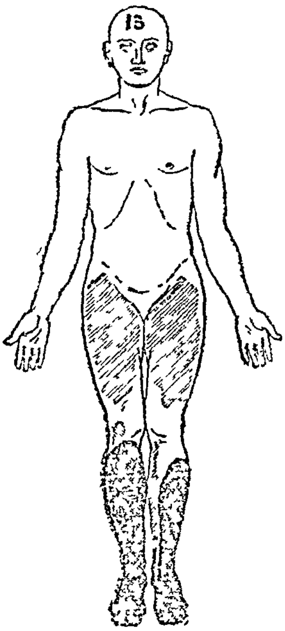
▨ Hyperæsthesia. ▩ Partial anæsthesia. ▦ Complete anæsthesia of his suffering at times appeared to render him delirious and he had threatened to destroy himself. The pain was soon referred to the thighs and the knee joints and had led to his being treated by liniments for rheumatism—in fact, the skin of his lower extremities was excoriated by the frictions and stimulations to which it had been subjected.



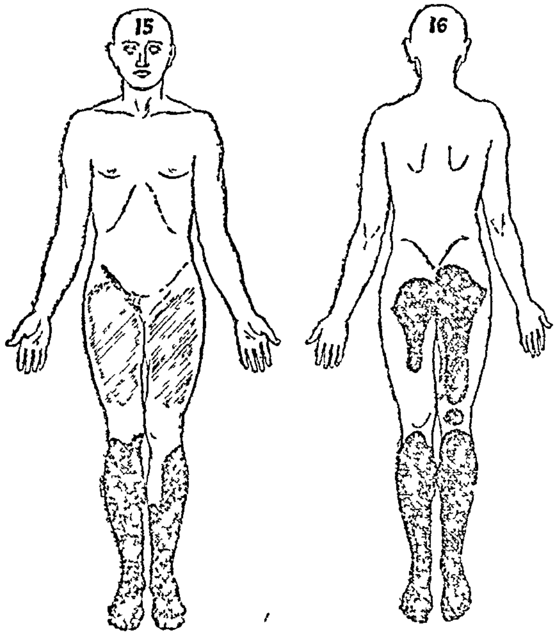
Jan. 15th. Motion and reflexes were as before. Sensation 5, 4, and part of 3 L., 1, 5, and 4 S.



Jan. 16th. Motor paralysis was present from 3 L. to 2 S on the right and from 5 L. to 2 S. on the left The reflexes were as before Sensation 5, 4 (incomplete on left), and lower part 3 L. (latter on right), 1, 5, 4, 3, and possibly part of 2 S.



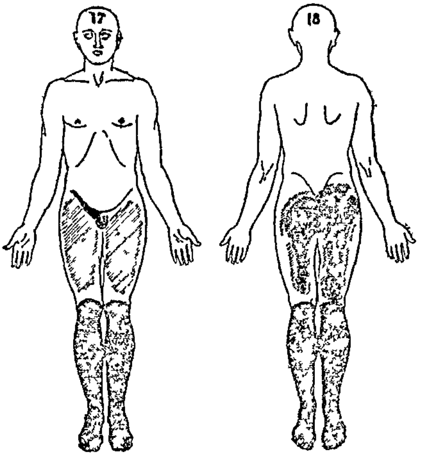
Jan. 17th. Similar to preceding.



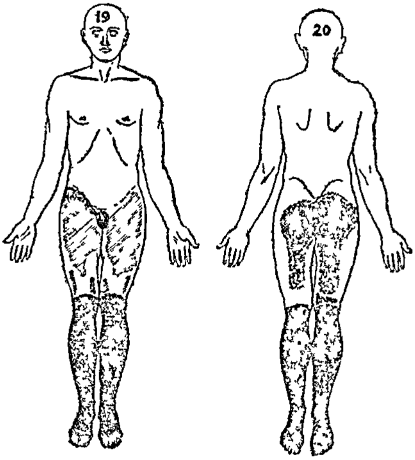
Jan 18th. There was complete loss of power in the legs from 3 L to 2 S The reflexes were as before Visceral paralysis was as before (detrusor vesicæ and possibly sphincter ani) Sensation 4 and 5 L on both sides 3 L on the right and commencing on the left. 2 and 1 L hyperæsthetic D 12 (L. 1 ?) on right only. 5 4, 3, part of 2 and all 1 S on the right, 5, 4, part of 3, and all 1 S. on left.

On admission the lad was tall for his age and of slender build. He was only comfortable when lying curled up with his back rounded and his chin flexed on his sternum. He complained that any extension of his head or any attempt to sit up without support caused acute pain in his legs. Notwithstanding this there was no tenderness, irregularity, or fixation of the spinal column, the whole being flexible and all the normal curves being easily reproduced. The lungs, the heart, the abdominal viscera, and the urine were quite normal. The ocular fundi were quite healthy and there was no evidence of any affection of the cranial nerves. The only abnormal signs discoverable were in connexion with the lower extremities. Although the legs did not appear to be wasted out of proportion to the rest of the body there was evident weakness both above and below the knees The boy complained of intense pain which he referred to the front and the sides of the thighs and to the knee joints The latter were not swollen. Tactile, thermal, and painful stimuli were everywhere discriminated and accurately localised. There was full control over the sphincters Of the reflexes the abdominal and cremasteric were present on both sides; the plantar were of normal flexor type, but the knee jerks were quite absent The temperature was 101° F on admission but fell in 24 hours to normal

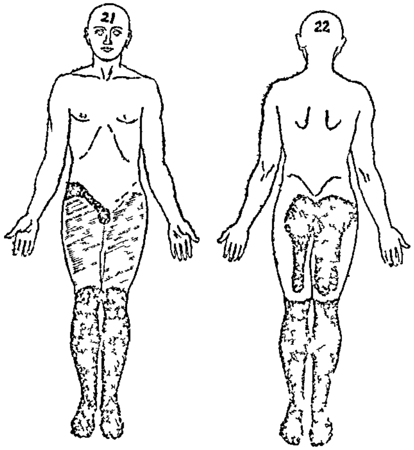
The patient continued to complain of the excruciating pain in his legs He could not sleep and was constantly shrieking and making attempts to get out of bed in the hope of finding some posture in which the pain might be less Areas of altered sensation soon became evident in the lower extremities and his subjective sensations of pain were found to be liable to paroxysmal exacerbations which were easily induced by movements of the thighs and legs or by pressure on the same parts



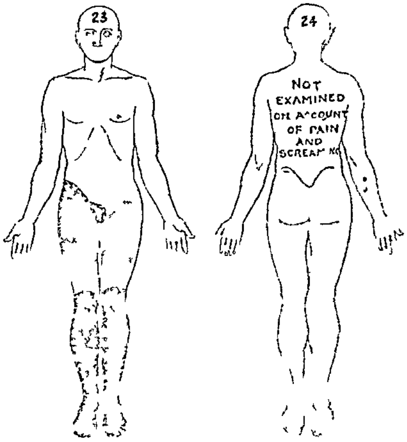
Jan 22nd Motion and reflexes were as before Sensation 3 L further defined also 12 D on the right (or is it 1 L ?) The scrotum was partly anæsthetic 3 S On the left 2 S probably almost complete



Jan 23rd The penis and the scrotum were quite anæsthetic, 3 S Motion and reflexes were as before



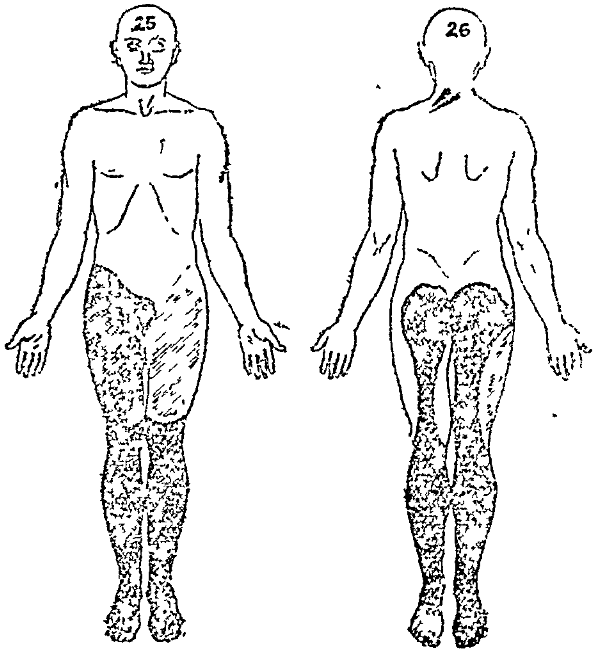
Jan 24th The additional field on the inner side of the back of the right thigh probably belongs to 2 L possibly to 3 S



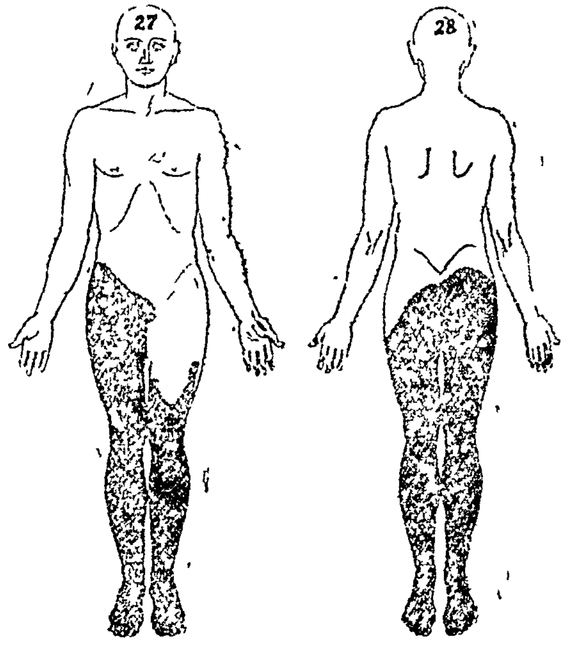
Jan 27th Motor paralysis by faradism was complete on both sides from 5 L to 2 S The left cremasteric reflex was not tested so it is doubtful if it were still present Sensory areas L 2 and 3 appearing on the right side

The distribution and the progressive march of the sensory abnormalities can better be appreciated by reference to the diagrams than by any verbal description In mapping out the areas there depicted the same procedure was always adopted, the tactile sense being tested with the feathered end of a quill pen and the painful sense with its point. At first attempts were made to test the temperature sense but these were soon abandoned, as the areas did not differ appreciably from those obtained by the other method If sensation were tested during the paroxysmal exacerbations of pain to which the boy was so subject anæsthesia was frequently found in areas where, in the intervals of freedom from pain, cutaneous sensation was present These areas of transitory anæsthesia were ignored in the diagrams, they corresponded fairly accurately with the areas marked as hyperæsthetic Zones of hyperæsthesia definitely surrounded the advancing sacral areas on the back of the thighs from the beginning

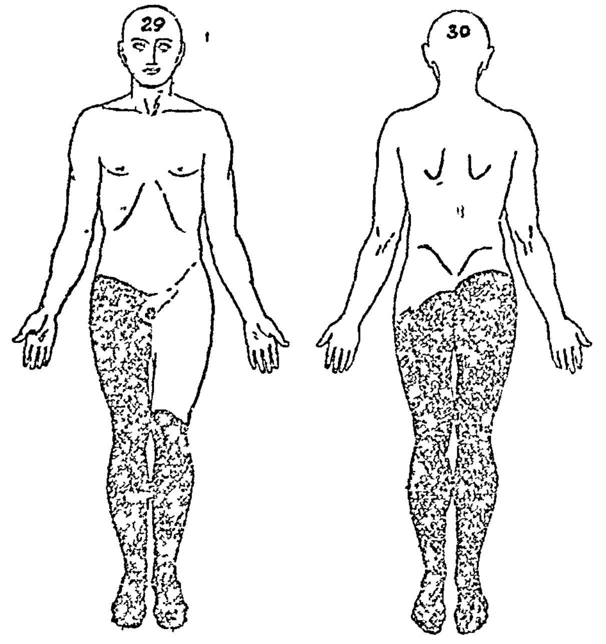
When the legs were first uncovered for testing sensation was always found to be more acute than after a few minutes' exposure to the cold. On some occasions after being tested intense itching was experienced in parts which had not yet become anæsthetic and on Jan. 23rd small red spots, not unlike the rose spots of typhoid fever, appeared at the points where the skin of the lowest part of the abdomen had been pricked. These spots persisted for several hours.



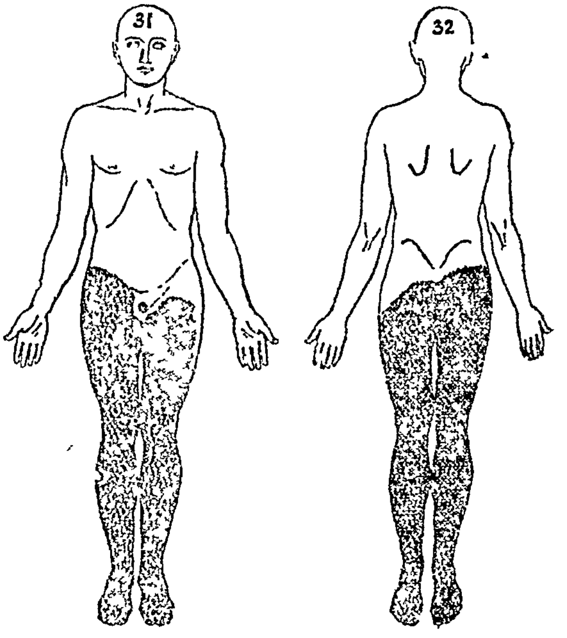
Jan 29th. The left cremasteric reflex had at last disappeared, 1 and 2 L. Posteriorly on the left side 4 and 5 L. and all sacral fields are shown. No note was taken as to the condition of the perineum.



Jan. 31st. The condition was as before the operation. The lower part of 2 L. now appearing on the left.

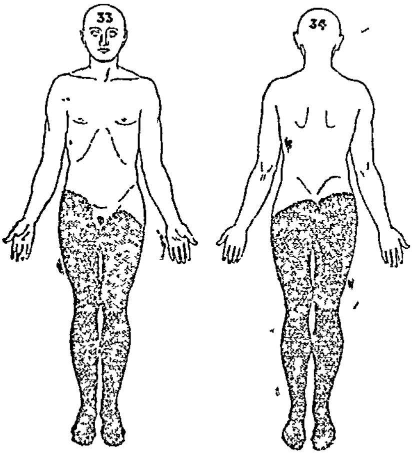


Feb. 15th (15 days after exploration). There was an improvement in the lumbar areas 2 and 3 on the left. Note sensation at the root of the scrotum.

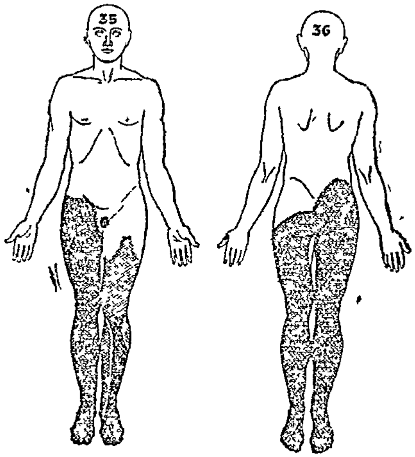


March 27th. There was some improvement in the muscles supplied by 3 and 4 L, but sensation in these areas was diminishing.

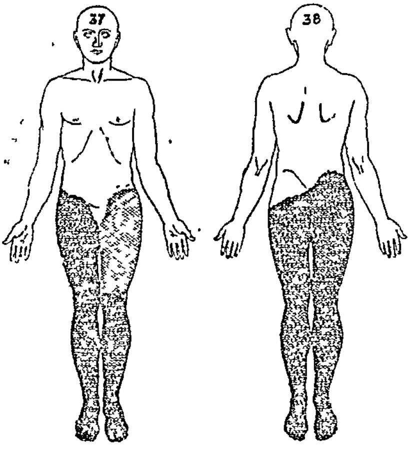
Five days after admission (Jan. 2nd) the plantar reflexes had both disappeared although the soles of the feet still retained common sensation. The loss of power in the lower limbs was progressive and the muscles were wasting rapidly. There was a loss of five eighths of an inch in the circumferential measurements of the calves between Jan. 1st and 3rd. Occasional incontinence of fæces became apparent on Jan. 5th. Later the bowels became constipated but control was still deficient and the loss became very evident after the use of aperients. By the 8th the right cremasteric reflex had disappeared and it was found that for two or three days past the boy had been assisting the emptying of his bladder by making firm pressure on his hypogastrium, a trick which he had discovered by accident. On the next day, after the completion of voluntary micturition, a catheter was passed and a further considerable quantity of urine was obtained. After this the atheter was used regularly. The feet had now become œdematous. Electrical examination of the muscles of the lower limbs proved impossible before the 11th on account of hyperæsthesia and screaming. It was not considered so urgent as to call for the administration of an anæsthetic. On the date mentioned the faradic excitability was greatly diminished in all the muscles of the right leg, including the ilio-psoas. In the left leg the muscles below the knee and the hamstrings showed a similar reaction, but the muscles on the front of this thigh reacted normally. Loss of power in the legs was quite complete by the 18th, there being now no power to effect any movement at all. The œdema of the feet had quite subsided but a small sacral bedsore had developed and others were threatening on both heels, but the skin never actually broke in the latter situations. Later a small bedsore developed over the right great trochanter but this ultimately healed also. Pain still occurred in paroxysms in the thighs and the knees, being particularly severe in the outer side of the left thigh and in the knee of that side The penis and the scrotum were quite anæsthetic by the 23rd. The electrical reactions were again tested on the 26th, when in addition to the muscles before mentioned, those on the front of the left thigh were found to have lost their faradic contractility entirely with the solitary exception of the tensor fasciæ femoris. *This muscle still reacted* slightly on strong stimulation. About this date cystitis occurred and bladder washing was commenced; this was continued up *to the time of transfer to the infirmary.* The left cremasteric reflex, which had up to now persisted, finally disappeared between the 23rd and the 29th. The tenderness of the fronts of the thighs had increased to such an extent that the boy could not bear the weight of his dinner plate on them



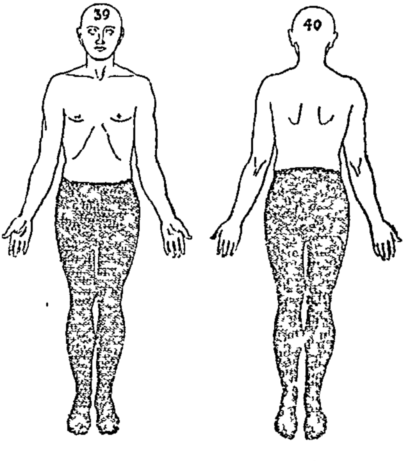
April 3rd. There was slight improvement in sensation below the left knee



April 24th. Indication of the division between the two areas on the front of the left thigh, 1 and 2 L



June 27th. Partial anæsthesia of 1 and 2 L. on the left.



A[illegible] ; in front up
[illegible] superior iliac
[illegible] Up to 11 D

On Jan. 31st laminectomy was performed by the late Mr. W. Anderson. The first, second, and third lumbar spines and arches were removed. The spinal theca was red, pulpy, and thickened. On opening the theca the cord itself presented a normal appearance The presence of a vascular new growth, involving the meninges, was suspected and a portion of the theca was removed for microscopical examination. What was thought to be a small bead of pus was observed outside the dura mater but this was doubtful and no further collection of pus could be found. Mr. S. G. Shattock reported that the microscopical examination of the piece of membrane removed revealed inflammatory changes with small areas of calcification. The operation was well borne and there was little or no shock. The wound soon soundly healed. Three weeks after the operation there was still no further control over the bladder and rectum. There was possibly a little power of voluntary movement of the muscles on the front of the left thigh, but with this exception the legs remained in a *condition of flaccid paralysis with loss of all reflexes. The* boy had been free from his pains for some days. Early in April some accession of power over the bladder and rectum was noted ; it was no longer necessary to draw off the urine by the catheter but the washing out of the bladder was continued.

A rounded prominence was beginning to appear in the neighbourhood of the laminectomy scar. This steadily developed into a firm rounded swelling extending rather more to the right than to the left of the mid-line and finally reaching from the spine of the tenth dorsal vertebra downwards for six and a half inches and measuring eight and a half inches across. This tumour was firm but not bony ; dilated veins coursed over its surface. Towards the end of June the boy began to complain of pain in his abdomen and examination revealed a smooth, fixed swelling of rounded outline deep in the right loin. This swelling was possibly the kidney pushed forwards by something behind it. The abdominal reflex was present on both sides and was very brisk. At this stage the control over the bladder and rectum was still partial and imperfect. Cystitis had almost disappeared. On August 17th, the day before transfer to the infirmary, anæsthesia to tactile, painful, and thermal stimuli was complete over both lower extremities. Its upper limit reached to the level of a line joining the two anterior superior iliac spines in front and extended a short distance above the iliac crests posteriorly.

During the whole period of observation the temperature varied but little from normal. *Usually the evening temperature* was slightly raised and on several occasions, at long intervals, it reached 101°.

As regards treatment, the pain was treated by opium, chloral, and hyoscyamus ; the cystitis by lavage, urotropine, and benzoates. Iodide of potassium was for a time exhibited in doses of ten grains thrice daily but with no appreciable effect.

Remarks.—This case illustrates in a remarkable way the subdivision of the surface of the lower limb into its nerve root territories. The areas on the whole correspond to those indicated in the classical contributions which Head has made to this subject. They differ in some respects from the areas according to Thorburn and the resemblance to the diagrams published by Kocher and by Starr is not very close, save in the mutual relation of the sacral areas of the back of the thigh as shown by the last-mentioned observer.

Unfortunately no precise indication for numbering these areas according to their roots of supply is afforded by this case. The boy's death did not come to my knowledge in time to render possible a post-mortem examination, and if one had been made it is extremely doubtful if much information in the direction desired could have been obtained, since the disease had progressed considerably and the legs had long been completely paralysed and anæsthetic. The sensory and the motor defects due to a progressive lesion of any one root do not necessarily appear simultaneously. The loss of sensation is often delayed until after the appearance of paralysis or loss of reflex. Consequently, by the time the anæsthesia does appear a fresh root or even more than one fresh root may be showing motor symptoms and so at first sight may appear to be associated with the cutaneous area properly belonging to the root first involved. It seems that something of this sort happened in the case now reported for the loss of reflex or the paralytic phenomena commonly attributed to the lesion of a particular root almost invariably antedated the loss of sensation in the skin area usually allotted to the root in question. Consequently neither the distribution of the motor paralysis nor the loss of a particular reflex can be taken as exact guides to the roots which supply the co-existing anæsthetic areas. I have therefore contented myself with indicating the condition of reflexes and as far as possible the extent of the paralysis at the times the different areas appeared and have not attempted to correlate the two. The lesion was presumably a new growth either of the meninges or of the bone and caused definite root symptoms as opposed to cord symptoms. The first definite objective symptom was absence of both knee-jerks (3 and 4 L.). This was followed by loss of the plantar reflexes (1 and 2 S.), marked wasting of the calf muscles (1 S.) and then anæsthesia of the dorsum of the foot and the outer side of the leg below the knee (5 L.). We may therefore conclude that the lesion commenced in the neighbourhood of the lowest lumbar and uppermost sacral roots and spread thence so as to involve roots in both the upward and downward *directions. Tracing the lumbar roots the indication seems* pretty clear that the fifth lumbar area on the outer side of the leg occupies its lower two-thirds only (Figs. 3, 5, 7, and 9). The indication that the fourth lumbar area on the inner side ceases at a corresponding level is not quite so clear; it possibly extends higher and may even come over to the outside above the fifth area (Figs. 7, 8, 15, and 35). Another area, traced from below, evidently stops a short distance above the patella, partly encircling the limb below this level. We have here the upper limit of the third lumbar area in all probability (Figs. 17 to 23 and 29 left side). The upper limit of the second lumbar area is indicated as crossing the thigh near the junction of the upper and middle thirds (Figs. 23 and 35). The first lumbar area is interposed between the preceding and the area in the groin (Figs. 17, 19, 21, and 23). The first lumbar area extends well round the outer face of the thigh. The area in the groin above mentioned will then be that of the twelfth dorsal root. It extends round the outer side of the limb to join the sacral areas on the buttock (Figs. 18, 20, and 22).

Turning now to the sacral root areas represented on the posterior aspect of the limb, and counting from above downwards, it appears that the areas represented in Figs. 6 and 8 on the right side are probably areas of the fifth sacral nerve, whilst on the left in Figs. 8, 10, and 16 the fourth sacral area is also represented. The third sacral area is added to these in Figs. 12, 14, and 18, whilst Fig. 17 shows the first involvement of the penis and the scrotum. The *anæsthesia of the penis and the* scrotum, although apparently developed in association with the anæsthetic area in the right groin, no doubt is properly associated with the long strip reaching nearly to the back of the knee-joint on the back of the thigh and attributed to the third sacral root. Figs. 29, 31, 33, and 35 show an area limited to the junction of the scrotum with the groin distinct from the penis and possibly belonging to one of the lower dorsal roots.

The area supplied by the second sacral root is obscure. It probably corresponds to an area at the back of the knee-joint, seen commencing in Figs. 12, 14, 16, and 20, and perhaps running up the thigh on each side of the third sacral root area (hyperæsthetic zone in Fig. 18). The first sacral area is taken as represented on the sole of the foot and partly on the back of the leg between the fourth and fifth lumbar root areas. All the sacral areas are evidently anæsthetic in Fig. 26.

Devonshire-place, W.

ON ALBUMINURIA AS AN ACCOMPANIMENT OF DIABETES MELLITUS.

BY F. W. PAVY, M D. LOND., LL.D. GLASG., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(Continued from p. 1498.)

I HAVE spoken of albumin making its appearance in the urine at various periods in the course of diabetes and it may now be stated that having appeared whilst unsatisfactory conditions existed it may disappear on the establishment of a more favourable state as regards the diabetes. The following cases may be cited in support of this assertion.

CASE 9.—The patient was a man who was 51 years of age at the time of coming under observation on Sept. 30th, 1895. He had then been suffering from diabetes for about one and a half years and was eating brown bread and drinking milk and soda-water a little freely. His symptoms were severe and his urine contained 55 5 per 1000 of sugar with a small quantity of albumin. Under treatment the sugar fell and by Oct 25th there was none. An irregular condition with respect to the albumin was noticed till Nov. 13th, which is the date on which its presence is recorded for the last time. The patient, it may be stated, afterwards continued under observation till November, 1900

CASE 10 —The patient was a man who was aged 44 years when first seen on Dec 16th, 1902 Diabetes had then existed about two years The patient was in a bad state and passed urine containing 45 per 1000 of sugar A trace of albumin was also present and hyaline casts were found in the centrifuged specimen A month later ' but with regard to albumin and before In June and in Augu coverable and at the latter date was no definite indication of albumin

CASE 11 —This patient was a woman My knowledge of her extends from February, 1902 She was then 70 years of age and had been the subject of diabetes for from 15 to 16 years Latterly she had grown worse and was taking a wrong kind of bread, supplied by a local baker Her urine contained 66 per 1000 of sugar A small amount of albumin and granular casts were also present The sugar soon fell to an insignificant quantity but the albumin and casts lingered The entry for August 8th, 1902 records the presence of a trace of sugar, a trace of albumin and granular casts The dates upon which the urine was afterwards examined were Oct. 16th, 1902, and April 18th, May 15th, and Oct 5th, 1903 Upon each occasion no albumin was found. No mention is made of microscopic examination till Oct 5th the date of the last interview, and then no casts were discoverable

CASE 12 —This patient, a woman, I first saw on Nov 8th, 1902 She was then 48 years of age and had been the subject of diabetes for two years Her urine contained 50 per 1000 of sugar and a trace of albumin On Nov 12th the sugar had fallen to 18 per 1000, with the albumin continuing as before The dates of the subsequent interviews were Nov 20th and 27th and Dec 4th and 16th, 1902, and Jan 4th, 1903 On all these dates there was an absence of albumin The sugar gradually fell and at the last interview it is recorded that there was none It will be observed that in this case it was only just at the beginning that albumin was present With the improvement that occurred in the diabetic condition it immediately disappeared Such a speedy disappearance is however exceptional and as has been shown by the cases previously cited the albumin may persist long after the sugar has been controlled

I take it that the cause of the consecutive albuminuria occurring in connexion with diabetes is a toxic influence of the sugar abnormally present in the blood upon the kidney The sugar that is eliminated has previously existed in the circulatory system and ought not to have been there With assimilation properly carried out sugar fails to show itself in the circulation as a result of the ingestion of carbohydrate food With faulty carbohydrate assimilative power, however, existing the carbohydrate of the food passes straight into the circulation in the form of free sugar and in this form subsequently runs off in an unutilised state with the urine There is thus an abnormal presence of sugar standing in proportion to the amount of carbohydrate food ingested in the contents of the circulation and everything conspires to show that it is to this sugar that all the ill effects of diabetes certainly of the "alimentary" form of it are attributable If the sugar be got rid of from the urine which may be read as meaning that the abnormality as regards sugar in the blood has disappeared, the whole of the symptoms of the disease vanish and remain absent as long as the state of the urine shows that things are being kept right Virtually such a person is in the position of a healthy one with the exception that carbohydrate food will cause sugar to escape with the urine in a manner that does not occur in the healthy subject Viewed in this way the sugar traversing the system in diabetes becomes an all important factor in connexion with the phenomena of the disease Not merely is it to be looked at as a food material which has failed in the proper place to have been put into a fit position to pass to utilisation, and is thence in transit through the system for escape but as an agent possessing the power of exerting toxic effects within the body It may be fittingly likened to alcohol in the position it holds in this respect and a close resemblance is traceable in many of the toxic effects produced Similarly its effects may be compared to those of a mineral poison, such as lead, arsenic, &c, obtaining slow entry into the system and producing a structural damage of the tissues Sugar, like these, tells hurtfully on the tissues, and if we give note to the nervous system closely concordant effects, in agreement also with those produced by alcohol, are found to be observable Peripheral neuritis may be pointed to as a very common issue from the play of all these toxic agencies

To the toxicity, then, of the sugar wrongly pervading the system I would ascribe the abnormality noticeable in connexion with the renal function That the kidney should yield to the toxic influence in operation more readily in some cases than it does in others is not surprising, looking at what occurs in connexion with other toxic agents—particularly may be mentioned alcohol Thus the variability which has been shown to present itself by the illustrative cases cited does not stand out of keeping with what is elsewhere noticeable

Stress upon the kidney through the extra amount of work thrown upon it is often spoken of as the source of the albuminuria that may be encountered In diabetes insipidus, however, it is not found that albuminuria becomes developed as it does in connexion with diabetes mellitus although an enormous elimination of urine may be occurring for a great length of time which we can hardly do otherwise than look upon as indicative of the existence of extensive strain upon the organ

In cases where diabetes mellitus has existed for some time the effect upon the kidney may be such as to lead to a certain amount of textural change being perceptible in the form of more or less interstitial overgrowth and abnormality implicating the epithelial cells of the secreting tubules Frerichs and Ehrlich comment upon the occurrence of a glycogenic degeneration of the epithelium of Henle's tubules as a result of diabetes and say that the cells may become packed with an accumulation of glycogen

As yet I have not referred to the special condition met with just prior to, and at the time of, the occurrence of diabetic coma It has been for some time known that with the advent of diabetic coma albuminuria attended with a profuse discharge of casts, becomes encountered as a concomitant phenomenon The discharge of casts may be such as to give rise to a light fluffy deposit forming a conspicuous settlement of sufficient amount to prevent escape from attention The deposit is virtually a sediment of casts possessing a somewhat characteristic microscopic appearance They are mostly short and wide and often at their ends look as if broken off They have a very distinct contour and are usually of a more or less highly granular structure The deposit is of diagnostic value foreshadowing as it does the supervention of the coma Whether casts have been discoverable or not previously, it is the sudden onset of an escape of casts sufficient to form a visible deposit which is predictive of danger Albumin does not stand in proportion to the casts Ordinarily the amount present is not large

With the condition of urine described the kidney gives strongly marked evidence of being the seat of morbid change. The acetone series of products which constitute the source of the coma evidently exert a pernicious action upon the organ It cannot be doubted that through the toxic influence of sugar alone the kidney may become damaged As has been shown, the presence of albumin in the urine may ordinarily be expected sooner or later to occur even in ' alimentary diabetes if the disease has not been kept satisfactorily under control When the disease has passed into the ' composite' type and the acetone series of products are associated with the sugar, experience shows that the proneness to the appearance of albumin is greatly increased a circumstance which is not to be wondered at seeing that there is now an additional toxic influence at work At the time of the onset of coma the accumulation of oxybutyric and diacetic acids is such as to suffice to throw the whole mechanism of the body out of working order and in these circumstances it is not surprising that the kidney should give evidence of being affected to the extent that is noticeable

The appearances that are found in the kidney where death has taken place from diabetic coma correspond with those that are produced by a renal irritant poison They are thus described in an article by Dr R Maguire on Albuminuria in Diabetes[1] He says "On microscopic examination I found the glomeruli intact but the epithelium of the convoluted tubes was greatly swollen in some parts hyaline, in others appearing as a confused granular mass which was very difficult to stain and which showed very few nuclei In many parts, too, the epithelium was detached from the walls of the tube " Ebstein had previously spoken of necrosis of the epithelium lining the convoluted tubes and the loops of Henle as an effect of the condition existing in diabetic coma.

---

[1] Brit Med Jour, vol ii., 1886

From the facts before us it is evident that the kidney becomes distinctly and profoundly damaged as a concomitant phenomenon of the condition existing in connexion with diabetic coma. The following cases give a representation of the clinical features belonging to the urine associated with the supervention of the coma.

CASE 13.—The patient was a woman, aged 67 years, when she became the subject of diabetes in 1898. Her brother had suffered from the same complaint. The disease set in with a sharp onset but was afterwards easily kept under control by diet. It remained until just prior to death of the "alimentary" type, but a satisfactory condition was not always found to be maintained by the patient. In November, 1901, she took cold which developed into a rather severe bronchial attack with myalgia affecting the neck and shoulders and giving rise to great distress. Her urine, which had previously been free from albumin, now contained a trace, and afterwards diacetic acid and acetone were present with a considerable amount of sugar. On Dec. 9th the urine contained 45 per 1000 of sugar by the indication of copper reduction and 38 per 1000 by the polarimeter, which showed the presence of a certain amount of oxybutyric acid. The appropriate tests also showed that diacetic acid and acetone were present. A slight amount of albumin was discoverable and microscopic examination of the centrifuged urine revealed an immense number of granular casts with sharp boundaries and for the most part short and wide. Knowledge of the above-mentioned particulars had been obtained before visiting the patient and I was expecting to find that signs would be presented of the onset of coma. These in reality were very distinctly noticeable. The patient was in a moderately advanced stage of diabetic coma and died on the following day.

CASE 14—The patient was a man, aged 52 years. I first saw him on Oct. 3rd, 1900. His diabetes had only recently set in and his symptoms were of a severe character. He was taking brown bread and a large quantity of milk. His urine contained 71 per 1000 of sugar. In 12 days' time the urine became free from sugar and remained so till the following December, notwithstanding even that three ounces of ordinary wheaten bread per diem were being taken for a short time previously. An unfavourable change now pretty suddenly set in. The sugar returned and for a time went on increasing and the ferric chloride test showed that diacetic acid had become present which at no time before had been the case. Subsequently some reduction of the sugar occurred and a certain amount of general improvement was noticeable, but this was the most that was observed. On Feb. 28th, 1901, the sugar stood at 27 per 1000; there was, as throughout previously, no albumin and only a slight ferric chloride reaction was obtained. The patient was next seen on March 21st. He had now lost ground considerably in every way. His weight had dropped to the extent of from six to seven pounds. His urine contained 43 per 1000 of sugar and gave a traceable indication of the presence of albumin, together with a strong ferric chloride reaction. Microscopic examination revealed numerous fragments of granular and hyaline casts. No signs of diabetic coma had as yet appeared but coma speedily afterwards set in and death took place on the 23rd.

CASE 15.—This patient, a man, I saw in consultation with Dr. J. Lees of Brixton on June 12th, 1902. He was 52 years of age and had been the subject of diabetes for seven years. He had about a fortnight previously taken a chill upon which pleurisy followed. Whilst progressing satisfactorily he imprudently got up and exposed himself to conditions which threw him into a serious state. It was at this time that I saw him. There were signs of incipient coma attended with the "air hunger" character of breathing belonging to it. The urine passed just previously to my visit contained 41 per 1000 of sugar and reacted, but not very strongly, with the tests for diacetic acid and acetone. There was a slight amount of albumin and a quantity of fluffy deposit settled out which consisted almost entirely of granular and hyaline casts. The shedding of these casts by the kidney was a strikingly prominent feature and yet associated with it there was only a comparatively insignificant discharge of albumin. The patient died on the day after I saw him.

It remains for me to speak of the bearings of alcohol on the albuminuria occurring as an accompaniment of diabetes. I have already stated that the sugar traversing the system to become eliminated with the urine may be regarded, by virtue of its toxicity, as the source of the various ill effects encountered in the uncomplicated or "alimentary" form of diabetes. I have also alluded to the correspondence in certain respects noticeable in the character of the deleterious results produced within the organism by sugar and alcohol, and it is left for me to say that, under the excessive use of alcohol, the damage supervening in diabetes becomes greatly intensified. Experience shows that where the toxic influence of alcohol has play in association with diabetes the condition is much aggravated and if the situation lasts on the progress of the disease is greatly accelerated. Renal damage has been shown frequently to attend diabetes, but it may with much greater certainty be expected to occur if there should happen to be the contributing influence of alcohol likewise in operation Peripheral neuritis arises both from the effects of alcohol and of diabetes, and from the evidence before us its development in the diabetic is without doubt much promoted by the intemperate use of alcohol. In connexion with the point under consideration I will cite the following cases.

CASE 16.—The patient was a man, aged 48 years when first seen on Jan. 21st, 1890. He had then been suffering from diabetes for nine months and was upon nearly the fully restricted diet for the complaint. His urine contained 9 per 1000 of sugar and was free from albumin. On the fully restricted diet his urine became free from sugar in two days and during the succeeding months remained in this state. In June evidence was afforded of returning assimilative power by loss of weight and a general feeling of weakness and depression.

I may perhaps be permitted to comment on this point and to state that I am often coming across in these circumstances the complaint by the patient of feeling low, weak, and dejected, with an empty sinking sensation in the epigastrium—a sensation as of something wanting, which I take to arise from the existence of a real want within the system. As long as carbohydrate cannot be assimilated it cannot be wanted by the system, and whilst the exclusion of carbohydrate food is needed to keep the urine free from sugar—in other words, whilst carbohydrate food would fail to be assimilated—no loss of weight occurs and no epigastric uneasiness attributable to the existence of a want in the system is experienced from the restricted diet. As soon, however, as carbohydrate assimilative power becomes restored carbohydrate food is proportionately wanted and if the system is not supplied with it the expression of want is manifested in the same manner as it is in the healthy person when food is cut off that is wanted. The precise mechanism in operation by which these phenomena are brought about cannot, it must be admitted, be explained, but everyone is acquainted with the results that are produced by cutting off food that the system can utilise and is therefore in need of. The fact of the phenomena referred to becoming observable in the diabetic shows a returning approach to the natural state and properly to meet the requirements an advance in the supply of carbohydrate should be made *pari passu* with the advancing return of assimilative power the signs of which are given by the information derivable from the weight and bodily feelings conjoined with a knowledge of the state of the urine.

Upon the strength of the signs of returning assimilative power that were presented, a little carbohydrate food in the form of ordinary bread was allowed. Two ounces per diem was the quantity in this case commenced with and upon it the urine remained in a sugar-free state and continued so after successive steps of increase till six ounces were reached, at which point the patient was advised to stop. This was in April, 1891, and throughout the remainder of the year and also when the urine was examined in 1892 there was an absence of sugar. In the early part of 1893, presumably as a result of dietetic deviation, some sugar reappeared and the allowance of bread had to be diminished and the ground to be retraced. A certain amount of irregularity, however, in the state of the urine was subsequently met with attributable to transgressions from time to time in diet. In this way matters proceeded till December, 1900, when a short time was passed in London in the society of friends whom he joined in a spell of alcoholic dissipation. His urine now contained a large amount of sugar conjoined with diacetic acid, which had not been noticed before, and a slight amount of albumin. In the following May the sugar was much reduced and there was a freedom from diacetic acid and albumin. The patient had learnt to realise the necessity of giving scrupulous attention to his mode of life and I note that at the last interview in June, 1903, his urine only contained traces of sugar and that it was otherwise in a perfectly normal state.

CASE 17.—In the case of this patient, a man, there was a strong family history of diabetes on the mother's side. I first saw him in April, 1893. He was then 39 years of age. Sugar had just been recognised in his urine through examination for life assurance. The case to begin with was a mild one and the sugar at first found disappeared under the strict diet accompanied with an allowance of six ounces of ordinary bread per diem. Till the early part of 1896 the urine kept free from sugar. In July, 1894, owing to a fall in weight having set in, the bread was raised to eight ounces which immediately stopped the fall and led to an increase. A further advance in the bread, with the allowance of some potato, was found to be tolerated and it was while the case was progressing in this way that the return of sugar occurred. There was evidence at this period that too much whisky was being taken and as time passed on the habit grew. Matters thus proceeded, the urine sometimes containing a certain amount of sugar and at other times none, till 1900, when a sort of climax was reached. The patient was now giving himself up to whisky-drinking to a highly pernicious extent. Previously his urine had been free from albumin and diacetic acid. In October, 1900 it contained both, with 34 per 1000 of sugar. In March, 1901, granular casts were in addition recognised, and in the following October, on account of the marked urobilin colour presented, attention was given to the liver and it was found that it extended down to from three to four inches below the margin line of the ribs. I should like for a moment to direct attention to the assistance derivable from the observance of this urobilin colour in connexion with alcoholism and the liver, and to say that it has often led me to examine the liver and, meeting with enlargement, to draw out information which probably would have escaped being spontaneously supplied by the patient. Through the summer of 1901 a little abatement of the unsatisfactory condition that had been noticed occurred, but at the interview on Oct. 9th a worse state than ever was met with The sugar stood higher and diacetic acid, albumin, and granular and hyaline casts were all found to have returned. The patient, who was feeling bodily ill and rapidly losing weight, now took alarm and resolved to pull in energetically both with respect to food and drink. The result was that on Nov. 27th the urine contained only a slight amount of sugar and gave only a traceable indication of the presence of diacetic acid and albumin. In the entry for Jan. 10th, 1902, an absence of sugar, diacetic acid, albumin, and casts is recorded. The general health had much improved and the liver was no longer to be felt. On March 7th and on May 9th the presence in the urine of a slight amount of sugar constituted the only abnormality observed, but the end of the turn of improvement that had occurred was now reached. The power to refrain from whisky no longer held out and at the next interview on July 4th sugar, diacetic acid, albumin, and casts had all returned in notable amount and the liver was again to be felt extending below the ribs. On afterwards substituting bitter ale for whisky a renewed start in the direction of improvement occurred. Diacetic acid was for a time lost and upon one occasion, May 7th, 1903, no albumin was to be found. Finally, however, the whisky temptation was too strong to be overcome. The patient averred that he had tried to do the right thing but could not tell me that he had succeeded. His associates drew him from his resolve to keep to the right course. His last visit to me was at the beginning of August and at the end of the month a letter reached me from his son stating that death had taken place somewhat suddenly and that the cause given in the certificate was acute bronchitis and heart failure.

The above cases suffice to illustrate the effect of the excessive use of alcohol in connexion with diabetes. There are no grounds for concluding that the temperate use of alcohol is prejudicial; indeed, my experience leads me to say that I consider it beneficial, but taken in excess there can be no doubt that it seriously aggravates the wrong state accompanying diabetes and in the damage inflicted throughout the system the kidney gives evidence of markedly participating.

It will be seen from what has been stated that the albuminuria which occurs in connexion with diabetes may exist for a long time without leading to the production of any symptomatic indication of its presence. The condition, therefore, is not to be looked upon as affording ground for apprehension in the same manner as when occurring under other circumstances. It is evident that albumin and casts have a very different signification according to the condition with which they are associated. Experience shows that even apart from diabetes they are with striking frequency come across in persons of advanced age presenting nothing to suggest the existence of renal mischief. They may, it is true, be the inceptive of something that may assume later on a more developed form, but, on the other hand, time may pass away and signs fail to appear of any further development. Caution under the circumstances is needed in framing an opinion regarding the future, and it is only by looking at the case in the broadest manner possible that a trustworthy conclusion can be arrived at.

Grosvenor-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF PERFORATED GASTRIC ULCER FOLLOWED BY HEPATIC ABSCESS.

BY H. HOLLIS, M.D. CANTAB.

THE patient, a female, aged 24 years, who had no important history of stomach trouble, fell from her bicycle and hurt her "chest" at the end of August, 1903. On Sept. 6th she ate her usual breakfast but only had French beans for dinner. In the evening, after walking for a quarter of a mile, she was sick and brought up a small quantity of blood, and was sick again after some brandy had been given. She was seen half an hour after the first attack of vomiting and being in a state of collapse was removed to the cottage hospital. There was great pain in the epigastrium, the face was blanched, breathing was thoracic, the pulse was 120, the abdomen was retracted and hard, and liver dulness was absent. Mr. W. E. Audland and Dr. W. I. Watson agreed with me that the patient probably had a perforation of the stomach. Four hours after the initial attack her abdomen was opened and a hole one-third of an inch in diameter was soon found in the centre of a roughly quadrilateral, greyish, sloughy-looking patch an inch long and three quarters of an inch broad situated on the anterior of the smaller curvature of the stomach. The patch was inverted, the stomach wall was sewn over it, and the abdomen, which contained a quantity of greenish fluid and several partly digested French beans, was thoroughly washed out. After the operation there was no sickness; the temperature was normal thirty hours after and it continued so for nine days. On Sept. 13th the wound was dressed and all the stitches were removed. On the 15th the temperature began to rise and the pulse-rate to quicken without any obvious cause or any discomfort. After a day or two there was thought to be increased dulness above the liver. The temperature now varied from 99° to 105° F. and on five days between Sept. 15th and Oct. 9th she had a rigor. On Sept. 23rd, 27th, and 30th a needle was put in the dull patch with negative result. On Oct 2nd there was some hardness in the abdomen below the ensiform cartilage, so the upper end of the operation incision was re-opened and an abscess in the liver was found, the contents of which were most offensive. A tube was put in and the wound was well packed with gauze. For two or three days the patient improved, then she gradually became worse and on Oct. 9th she died.

Post mortem the liver was found to be adherent to the upper part of the abdominal wound and to a small patch of the diaphragm. In the left lobe there was an abscess cavity and a small abscess as large as a Barcelona nut was found in the spleen. The wound in the stomach was quite healed and, indeed, was difficult to find. In the right lobe of the liver were two small dark patches at the site of the exploratory punctures. There was no peritonitis and all the other organs were healthy.

It seems difficult to account for the abscess as it does not appear to have been part of a general pyæmic condition and the late onset, nine days after operation, and the absence of peritonitis do not point to any connexion with the ulcer. As the patient had never had any vomiting or hæmatemesis can it be possible that the fall from the bicycle was the cause of both lesions?

Wellingborough.

FEVER, FOLIACEOUS DESQUAMATION, MORBILLIFORM ERUPTION, AND ALBUMINURIA FROM COPAIBA.

BY J. C. MCWALTER, M.A R U.I., M.D. BRUX., D.P H.

WHEN a patient presents himself with a copious rubelloid eruption, a temperature of 102° F., some congestion of the tonsils, and complains of being deadly sick, one naturally suspects scarlet fever. When, further, the patient is uncertain if he has ever had that disease, when he works in a large butter shop and lives in a lodging-house, and when his urine on being examined is found to contain albumin, the practitioner who decides that he is not dealing with a case of febris rubra undertakes a grave responsibility.

In the present instance, however, the whole phenomena were apparently due to the administration of copaiba in a case of acute gonorrhœa. The sufferer was a young man, aged 22 years, who had been taking 20 minim doses of copaiba whilst his affection was in the inflammatory stage. Although the rash which he exhibited was not unlike a copious copaiba eruption, the temperature of 102°, which had only abated to 101° by the next day after he had ceased to take the medicine and remained in bed, the general feeling of malaise, the throat conditions, and the fact that after three days a desquamation so considerable set in that foliaceous flakes of epithelium were shed off and regular casts of his fingers could be removed, led me to fear that I had been mistaken in attributing the eruption to the drug. This seemed to be the more likely as albumin was present in the urine in the earlier stage, though it quickly passed off Finally, I sent the patient to the fever hospital but the staff concurred in the view that the symptoms were due to the copaiba and the patient got all right after four or five days though the desquamation continued somewhat longer. Evidently the disease plus the drug had produced a transient acute nephritis.

It is complacently laid down in text-books that when one has doubts whether a febrile eruption be scarlet fever it is safer to treat it as such. But the problem is nowadays not so simple. If a case is declared to be scarlet fever and a working man is sent to hospital and loses his situation he will have a legal remedy against the practitioner if there be any doubt as to the diagnosis. Should he work in a dairy or a butter shop the proprietors will have something to say if they are wrongly tainted with the suspicion of employing a scarlatinous servant; and, on the other hand, if the man really has an infectious disease in such a situation the danger is appalling.

KING'S COLLEGE HOSPITAL.

A CASE OF PNEUMOTHORAX OCCURRING THREE DAYS AFTER INJURY TO THE CHEST.

(Under the care of Mr. F. F. BURGHARD.)

FOR the notes of the case we are indebted to Mr. Neville Hart, acting house surgeon.

A boy, aged six years, was admitted into King's College Hospital at 11.45 P.M. on August 31st, 1903, having been run over by a hansom cab with three people in it. The wheel, both from the marks on his coat and abrasions on his body, appeared to have passed from about one inch above the right iliac crest to the neighbourhood of the left axilla. His lungs previously to the accident were probably healthy. When seen some ten minutes after the accident he was severely collapsed; he was pale, with blue lips and cold extremities, his temperature being in the rectum 95·7° F. and his pulse 154, small, irregular, and unequal. He was not unconscious but was in a restless and excited condition. His respirations were 40 and accompanied by an expiratory "grunt." His abdomen was full and moved only very slightly on respiration; it was very hard and tense but not particularly tender. The note all over the abdomen was decidedly tympanitic, the liver dulness being normal with the exception of a somewhat square patch below the ribs which was absolutely dull. His flanks were resonant; his spleen was unpalpable and its dulness was normal. On examining the chest the left side was seen to be immobile and flattened and several ribs on that side were broken. The epiphysis of the right clavicle was separated. On palpation the heart's apex beat was found in its normal place and the crepitus of the broken ribs was very marked. The percussion note was normal all over the chest and the cardiac dulness was unaltered. On auscultation a loud rasping sound was heard all over the left base which was probably due to the friction of the lung against a broken rib. In addition to this a loud "thumping" sound was heard even several feet away. With the stethoscope it appeared to be best heard over the epigastrium. Excessive tenderness was present all over the left side and this made examination difficult. There was no sign or history of blood being brought up nor did vomiting ever occur. The patient was at once put to bed in a partially recumbent position with hot-water bottles to his extremities, but he was very restless and there was a tendency to cyanosis. Oxygen was frequently administered and brandy was given diluted with hot water. At 1 30 A.M. his pulse was weaker and fluttering and strychnine was given hypodermically. Soon after this reaction took place and reached its height at 4 A M. The skin got warm, the face flushed, and the eyes brightened. His pulse rose to 184 and at 4 A.M. it was full and regular. His temperature rose steadily, being normal at 2 A.M., 100·2° at 3 A.M., and 100·8° at 4 A M. His general condition was much improved but the dyspnœa was accentuated and he sat straight up; whenever there were signs of cyanosis oxygen was administered. He was still given brandy, though in small quantities and less frequently. He now passed 14 ounces of urine which was quite normal and contained no blood. His respirations reached 48 and increased in rate till 2 P.M. on the next day when they were at 64.

On Sept. 1st at 10 A.M. the dyspnœa was still extreme. The dulness below the liver already referred to was not now found. The signs in the chest were unaltered in front; the back was not examined owing to the patient's critical state. His general condition varied enormously from time to time and his pulse was frequently very weak and irregular. He was ordered spiritus ammoniæ aromaticus and digitalis in a mixture, the benefit of the latter being apparent in the early hours of the next morning when his condition became very critical. Warm brandy and water were administered frequently throughout the day and he had nutrient enemata twice. The child took his milk greedily and without vomiting. On Sept. 2nd at 10 A.M. he was better, though his eyes were sunken and his dyspnœa was marked, but rather less so than on the 1st. There were a few râles at the left apex and weak breath sounds were heard there; at the base the breath sounds if present were still quite obscured by the rasping sounds already described. At the back of the thorax the breath sounds of the left lung extended rather farther down and there was a patch of absolute dulness at the left base. The sounds all over the right lung were louder and somewhat harsher than normal. The administration of oxygen was discontinued and though the patient still took the spiritus ammoniæ aromaticus the brandy was omitted. On Sept 3rd at 10 A.M the temperature was 101°, the pulse was 192, and the respirations were 84 The child, who had been beginning to take a lethargic interest in things in general, was cyanosed and again in great distress; he was irritable and restless and on examination the condition of his chest was found to be very different. The left side though flat was not so flat as before and was absolutely immobile. The heart's apex beat was seen in the sixth intercostal space just beyond the right border of the sternum. Vocal fremitus had gone completely from the left side, except over a small area at the left apex. The percussion note was high-pitched all over the left side and in parts almost dull, except at the apex which had its normal note. *Bruit d'airain* was not obtainable. No breath sounds could be heard over the left lung except at the apex and no vocal resonance could be made out. At 4 P.M., as the heart was still travelling to the right and its left margin was getting further and further from the sternum, it was *decided to aspirate. This was done shortly after, the needle* being inserted just below the angle of the left scapula, and ten ounces of blood were withdrawn, followed by a considerable quantity of "air." At first only two or three drops of blood were obtained through the large-sized needle, the remainder being very gradually removed with a Potain's aspirator. The heart returned very nearly to its normal place. At 7.30 P.M. the heart was found to be in its former *position and the physical signs* were as before aspirating with the exceptions that amphoric breathing was now heard in front and that the bell sound was obtained. The general condition, however, had wonderfully improved and was not at all critical. The pulse, temperature, and respiration came steadily down. His colour also improved and the expiratory "grunt" ceased. He again took an interest in his surroundings and that night, for the first time *since admission, slept comfortably. On Sept. 4th* the improvement was maintained. The left chest now moved slightly and the spaces of its lower part were seen to be sucked in with inspiration. The heart was in the same place. There was a loud flapping sound heard behind, its *maximum intensity being at the level of the angle of the* third left rib. The bowels were opened. On Sept. 5th the temperature touched normal and from this time onward the *patient's condition steadily improved, his heart gradually* returning to its normal position and the ordinary breath sounds reappearing from above downwards. He developed a slight cough on the 7th which soon passed off. On the 9th his condition was so good that an x-ray photograph of his chest was taken by Mr. Reid which showed that the ribs from the second to the seventh were fractured. A pneumothorax was sharply defined, extending from the sixth to the *tenth rib, the lower lobe of the left lung being imperfectly* seen collapsed near the spine. The upper lobe of the lung was apparently normal in appearance. The heart was pushed to the right side, the left border corresponding with the left side of the spinal column. A subsequent photograph taken eight days later showed that the left lower lobe had com*pletely expanded and that the heart had resumed its normal* situation The patient was discharged on Sept. 28th.

Remarks by Mr. BURGHARD.—The case has many points of interest: (1) though the injury to the chest was great and several ribs were broken the injury to the lung was probably small since no blood was at any time brought up or passed by the bowel, whereas these signs are commonly seen after such an accident; (2) the occurrence of pneumothorax some days after the accident, possibly due to the friction of the broken end of the rib; (3) the rapid improvement *after aspiration, the temperature coming steadily* down; and (4) the loud flapping sound heard chiefly behind —this was considered to be due to the lung as it expanded hitting the parietes.

LONDON TEMPERANCE HOSPITAL.

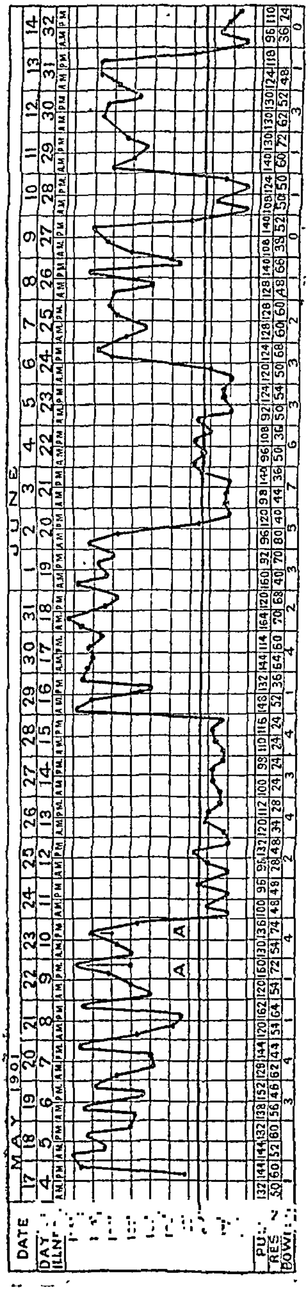
A CASE OF RECURRING BRONCHO-PNEUMONIA.

(Under the care of Dr. W. SOLTAU FENWICK.)

FOR the notes of the case we are indebted to Dr. Herbert Rhodes, senior resident medical officer.

The patient was a boy, aged two years, who was admitted into the London Temperance Hospital. The history showed that he had always been healthy, except for one attack of bronchitis, until May 13th, 1901, four days before admission, when he was sick, feverish, and short of breath. The breathing became easier during the next 12 hours but the child remained hot and restless. There was no family history of constitutional disease.

On admission the child was found to be well-nourished, the mucous membranes were pale, the face was flushed, the respiration was rapid, but there was not much cough. On examination of the chest no signs of disease were detected in the right lung. The left lung showed the usual evidence of pneumonic consolidation and pleurisy at the base of the upper lobe. The temperature fell to normal on the 24th and on the 26th signs of resolving pneumonia were found at the base of the upper lobe of the left lung. There was no general bronchitis. After a period of apyrexia lasting five



A, sponged. The vertical lines in these two columns indicate the reduction of temperature produced thereby.

days the temperature rose again on the 29th to 104 4° F. and there were now signs of consolidation at the apex of the right lung. On June 2nd the temperature again fell to normal and the signs of consolidation disappeared from the right apex, but on the fourth day—namely, on the 6th—the temperature again rose to nearly 104° and signs of pneumonia appeared at the apex of the left lung. Although the temperature fell on the 9th (the twenty-seventh day of the illness) for 24 hours, it rose again on the 11th and fell to normal finally on the 13th after a patch of dulness and bronchial breathing appeared at the left base. The child remained very anæmic and weakly for some time but made a perfectly satisfactory convalescence and was discharged cured on July 12th, 1901.

The interest of this case lies in the apparent infection of new areas of lung tissue on three occasions, there being but a very short period of apyrexia between each recurrence. The treatment consisted chiefly in the exhibition of such expectorants and stimulants as ipecacuanha wine, ammonia, and musk. During part of the patient's sojourn in hospital he took two-drop doses of guaiacol three times a day but this drug did not appear to have much influence on the course of the disease.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

A Contribution to the Pathology of the Thymus Gland.—Enlargement of the Prostate.—Unusual Tumour of the Skull.—Calcifying Chondro-sarcoma of the Breast.—An Unusual Form of Obstruction of the Colon.

A MEETING of this society was held on Dec. 1st, Mr. RICKMAN J. GODLEE, the President, being in the chair.

Mr. L. S. DUDGEON read a short abstract of some work which he had done in the Pathology of the Thymus Gland. He stated that his observations were based on an examination of 105 children of all ages. The thymus gland was also examined in a large number of adults, fœtuses, and various animals. He considered that the normal weight of the thymus in children was from seven to ten grammes. He collected 16 cases of "sudden death" and "children found dead." The average weight in these cases was 25 grammes. Thick yellow fluid was found in the interior of the gland in all large and enlarged gland and consisted almost entirely of lymphocytes and was not pus. It had nothing to do with congenital syphilis such as Dubois stated. In seven cases out of eight examined this fluid was found to be sterile. In one case the pneumococcus was found in pure culture and the fluid was found to be pathogenic to mice. All varieties of eosinophiles were the most characteristic cells in enlarged thymus glands. Hæmorrhages were found in the thymus in 95 per cent. of cases of deaths from broncho-pneumonia or lobar pneumonia. 15 cases of marasmus were examined. The average weight of the gland was two grammes, and atrophy of the lymphoid corpuscles and replacement by endothelial cells and connective tissue were the commonest histological changes. Similar changes, however, were often found in cases of secondary atrophy.—Dr. H. MORLEY FLETCHER asked if the structure of Hassall's corpuscles varied as they occurred in the thymus of the fœtus, in the thymus from cases of marasmus, and in the thymus of the adult.—Dr. C. R. BOX asked if there was any evidence to show that the marasmus occurring in children was due to the atrophy of the thymus. He also asked what was the cause of sudden death in these cases of enlarged thymus.—Dr. F. J. POYNTON said he did not think that the atrophy of the thymus was out of proportion to the general wasting in these cases of marasmus. He suggested that the fluid obtained from the gland should be centrifugalised and the clear fluid used for injection into animals in order to prove if it possessed any active substance.—Dr. J. H. THURSFIELD said that he had reported four cases of sudden death from enlarged thymus occurring in children. He did not think that asphyxia was the cause of death in these cases as the thymus, although large, was soft and pulpy and could hardly cause pressure on the trachea sufficient to cause death. The other view suggested was that death was due to some toxin produced by the thymus and circulating in the blood. He thought, however, that the cause of death was still uncertain.—Mr. W. G. SPENCER said that the swelling in the neck due to enlarged thymus was often easily felt and that the condition during life was very different from that found at post mortem examination. He stated that it had been shown by Wooldridge that the thymus gland possessed fibrinogen and the power of rapidly coagulating blood.—Mr. S. G. SHATTOCK said that he thought little reliance could be placed upon the staining reaction with van Giesson's stain, since the staining varied according to the manner in which it was used and the nature of the mixture.—Mr. DUDGEON, in reply, said that he thought the general marasmus and atrophy of the thymus went hand in hand. He did not believe that sudden death was due to coagulation of blood as he had never found thrombosis on post-mortem examination.

Mr. CUTHBERT S. WALLACE read an anatomical criticism of the procedure known as Total Prostatectomy. He first of all called attention to the following points in the structure of the normal prostate:—1. That there was no division into lobes. 2. That the circumferential portion of the gland was composed of fibro-muscular tissue and devoid of gland tissue. It was suggested that the term cortex, as proposed by Mr. Shattock, should be applied to this part of the organ. 3. That the part of the organ immediately in front of the urethra was also devoid of gland tissue and was the structure known as the anterior commissure. 4. That in a cross section at right angles to the axis of the urethra the fibro-muscular tissue was seen to radiate outwards and to join the circumferential portion of the organ. 5. That the gland tissue was most marked at the sides of, and behind, the urethra. 6. That outside the cortex lay the fibrous sheath derived from the recto-vesical fascia and in this was imbedded the venous plexus. This sheath was not a definite structure, such as the fascia lata of the leg, but consisted of a number of areolar planes in which fluid could extravasate. This structure would form the boundaries of the cavity left if the prostate was removed entirely. A specimen typical of the parts removed in the so called total prostatectomy was next shown. Special reference was made to the so called capsule seen on the surface of the tumour. A cross section showed a central glandular portion containing the urethra, the whole surrounded by an apparently fibrous capsule. Specimens of bladders with enlarged prostates removed after death were next considered. The first had been studied by means of cross sections at right angles to the axis of the urethra. The enlargement was seen to consist of a central glandular portion containing the urethra and a circumferential envelope. This was a dense laminated structure which admitted of cleavage in many planes. It contained gland tissue and was therefore derived from more than the outer non-glandular cortex. It was next shown that the central portion could be shelled out from the envelope and that the amount of envelope left on the central portion would depend on the depth to which the finger penetrated into the envelope. In the second specimen the front of the bladder and of the enlarged prostate had been removed by a coronal section. Adenomatous masses had been shelled out from both lateral parts of the organ. A median ridge representing the posterior wall of the urethra was left behind; the lateral walls of the canal had come away on the surfaces of the adenomata. The wall of the bilocular cavity thus left was a very definite structure and was found capable of further division, which division resulted in the removal of a bilocular envelope. After removal of the envelope there was still left behind a very definite wall bounding an unilocular cavity. This wall was shown to contain gland tissue and must have therefore been derived from the glandular part of the organ. Outside this wall lay the prostatic plexus of veins. If the two adenomatous masses were replaced in their envelope it was seen that the mass resembled the parts removed in the so-called total prostatectomy. The formation of the adenomata and of their envelope was then traced and it was shown how the growth of the adenomata stretched the prostatic tissue over themselves and forced the fibres to take up a circumferential direction and to form the definite envelope seen in the previous post-mortem specimens. The size of the organ had no definite relation to the progress of the adenomatous change. One specimen removed during life and weighing 150 grammes was identical in appearance with another also removed from a living patient which weighed only 20 grammes. The type of enlargement depended on the point at which the adenomata developed. If they grew in the lateral lobes then two adenomata might be removed either singly or encompassed by an envelope If the growth increased at the same rate throughout the glandular area of the organ then the parts removed would consist of an adenomatous mass practically surrounding the urethra. The so called median lobe was always continuous with one or both of the lateral lobes It was then pointed out that the glandular masses surrounded by the inner *most part of the envelope enucleated from the parts removed* after death corresponded accurately to those removed by the so called operation of total prostatectomy in the living subject It must be concluded therefore that the parts left behind in these two procedures corresponded Now in the case of the parts removed after death after an enucleation such as had been described there was left behind a definite envelope This envelope had been shown to contain gland tissue and therefore to represent more than the non glandular cortex External to this envelope the prostatic venous plexus had been shown to lie It therefore followed that after the so called total extirpation of the pro tate an envelope formed of expanded prostatic tissue was doubtless left behind and bounded the cavity formed by the removal of the tumour From the facts detailed above the following conclusions were drawn (1) that the usual form of prostatic enlargement was an adenomatous one, (2) that the adenomatous masses might surround the urethra or form masses in the lateral lobes, (3) that the parts removed might consist of adenomata from the lateral lobes or of an adenomatous mass surrounding the urethra, (4) that there was always left behind a definite laminated envelope containing gland matter, (5) that the amount of envelope left on the surface of the tumour depended on the point at which the enucleating finger entered the envelope, (6) that the recto vesical fascia was not opened and therefore the prostatic plexus veins were not injured, and (7) that though it was pos ible to remove small adenomata from the central part of the lateral mass of the prostate without extensively injuring the urethra yet this canal was removed *in toto* when the adenomatous growth surrounded the urethra and the lateral walls were removed on the adenomata when these were of any size *It was suggested that the name* 'surgical capsule should be applied to this envelope formed by the expansion of the adenomata, it was a pathological product and represented more than the cortex To its presence was due the small amount of hæmorrhage and the absence of urinary extravasation The enucleating finger never passed outside the limits of the prostate, it could not therefore enter the recto vesical fascia or tear the prostatic venous plexus — Mr G H. MAKINS said that these observations showed that the recto vesical fascia was not opened up in the operation *known as total prostatectomy and hence the danger of* extravasation of urine into the tissue and the danger of hæmorrhage were avoided —Mr E M CORNER said that if the bed from which the prostate had been enucleated was examined by the finger it was found to have an even surface and quite different from the loose tissue of the recto vesical fascia and this accounted for the rarity of extravasation of urine and of hæmorrhage after removal of the prostate — Mr SHATTOCK said that the specimen showed that the entire prostate was not removed but there was always left behind a layer of glandular and fibrous tissue

Dr H A LEDIARD read an account of a case of Thyroid Malignancy The specimens shown were from a woman aged 42 years who was treated in the Cumberland Infirmary during March, 1903 A goitre had existed for years and was succeeded by a growth in the frontal region of 12 months' visible appearance The removal of the secondary tumour was imperative and the frontal bone was found to be penetrated by a growth resembling goitrous tissue The size of the perforation was over two inches in diameter The brain was not involved The thyroid gland was cirrhotic and showed fibrous and calcareous changes together with an adenoma of small size growing actively the tubules of which were invading the thyroid tissue The secondary growth in the skull showed spaces filled with colloid material similar to ordinary goitre This metastasis was associated with goitres of long standing and the cranial bones were selected by preference Three similar cases were recorded in the Transactions The paper was illustrated by micro photographs slides and lantern views *Dr Lediard claimed to have traced the secondary growth in the skull to the adenoma growing in an old goitre and* suggested that thyroid malignancy hitherto obscure was now satisfactorily explained

Mr O A MORTON showed a Calcifying Chondro-Sarcoma of the Breast removed from a woman, aged 64 years, which was very hard and heavy It was round with a diameter of one and three quarter inches, harder than scirrhus but not glistening, and contained many areas of calcification Secondary growths of the same nature appeared in the gluteal region 15 months later Microscopical sections showed a mixture of sarcoma cells and cartilage In some areas the cartilage had a hyaline matrix, but in others large numbers of cells like cartilage cells were crowded together without any matrix Tumours of the breast containing cartilage were in the great majority of cases sarcoma Four other cases of the kind were recorded in the Transactions of the society

Mr MORTON also showed an Unusual Form of Obstruction of the Colon A portion of the transverse colon six inches in length formed the obstruction The wall was very greatly hypertrophied and the mucous membrane was thickened, honeycombed and extensively separated from the muscle coat beneath but not as a slough This very extensive separation of the mucous membrane without necrosis was the most striking feature of the specimen It seemed likely that the honeycombed appearance was due to old ulceration The almost detached mucous membrane formed a sort of network within the bowel composed of fine spiral rods the whole mass resembling somewhat a collection of fine white worms Symptoms of chronic obstruction had been present for a long time and a history of syphilis suggested that as the possible origin of the ulceration

CLINICAL SOCIETY OF LONDON

Chronic Intussusception treated by Intestinal Resection — Cases of Lymphocythæmia —Post operative Hernia treated by the Introduction of Silver wire Filigree

A MEETING of this society was held on Nov 27th, Dr FREDERICK TAYLOR the President being in the chair

Mr F C WALLIS gave an account of a case of Chronic Intussusception treated by Intestinal Resection (illustrated by the epidiascope) which is published in full at p 1659 of our present issue —Mr A. E J BARKER remarked that it was not uncommon for the lower part of the bowel into which intussusception had taken place to slough It should always be very carefully examined at the time of operation He preferred simple suture to the use of Murphy s button in such cases —Mr W BRUCE CLARKE remarked on the importance of cutting through absolutely healthy bowel He concurred with the previous speaker in preferring end to end suture rather than Murphy s button —Mr WALLIS replied

The PRESIDENT read a paper on two cases of Lymphocythæmia (Lymphatic Leukæmia) The first case was that of a boy aged ten years who first complained of pains in the legs thirst and yawning Six weeks later he was found to have enlargement of the left parotid gland, dulness over the upper part of the sternum a deep seated tumour in the left flank but no obvious enlargement of the lymphatic glands Two weeks later he was admitted into Guy's Hospital with enlargement of both parotid and submaxillary glands of the liver, and of the left kidney A blood count showed 15 000 leucocytes per cubic millimetre *of which 46 per cent were small lymphocytes* A few days later the parotid swellings had increased and some lymphatic glands close by had enlarged, but there was no general increase in the size of the cervical glands or of those in the axillæ or groins Each lacrymal gland was felt as a hard mass between the orbital ridge and the eyeball The leucocytes increased to 50 000 and a differential blood count gave small lymphocytes 94 large lymphocytes 3 polymorphonuclears *2 5 and eosinophile 0 5 per cent Hæmorrhages from the* mucous membranes appeared and he died a month after admission The post mortem examination showed enlargement of the above mentioned glands also of the thymus spleen and kidneys Microscopically the enlarged organs were densely packed with lymphocytes The second case was that of a girl, aged 14 years who was seen on Jan 14th Six weeks previously she had had pains in the limbs with malaise The mammæ had been noticed to be enlarging Her eyes became prominent and two days after the feet swelled She was pale dyspnœic and had œdema of the eyelids The salivary glands were enlarged the mammæ were enlarged, hard and nodulated The liver reached one inch below the umbilicus. The edge of the spleen could just be felt The lymphatic glands in the axillæ and groins were not specially enlarged. A blood film showed an extraordinary excess of leucocytes, of which 95·8 were small lymphocytes. She died on Feb. 21st, after the onset of ascites, epistaxis, and uterine hæmorrhage. The rapid course of both these cases and the enlargement of the mammæ and the thymus were unusual features. The relatively small size of the lymphatic glands suggested that these organs were not primarily at fault.—Dr. H. BATTY SHAW asked what was the condition of the marrow in these cases. The enormous enlargement of the kidney must be regarded as accidental, like the red deposits which might occur subcutaneously and in various other positions. Some believed that such deposits were produced by the changes in the marrow but others regarded the change in the lymphatic glands as the originating factor of the disease, those in the marrow being secondary. The fœtor of the gums was not an invariable feature.—Dr. F. PARKES WEBER suggested that the bone marrow was in all probability the chief source of the disease. In every case in which the marrow had been examined it was found to be changed. Cases had been recorded in which the bone marrow was the only leucocyte-forming organ at fault, the lymphatic glands being healthy. Lymphocytes should, in his view, be regarded as an undifferentiated or fœtal variety of myelocytes.—Dr. A. G. PHEAR remarked on the small size of the lymphocytes in these cases. He believed that the large and small lymphocytes had a separate origin. The bone marrow could not be regarded as a source of the large lymphocytes.

Mr. LAWRIE H MCGAVIN narrated a case of Post-Operative Hernia of the Abdominal Wall treated by the Introduction of a prepared Silver Wire Filigree. The patient, a woman, aged 47 years, had undergone an operation 15 years previously for the removal of a uterine fibroid and had developed a ventral hernia at the site of the old operation of such dimensions that the chances of obtaining a permanent cure by the usual surgical procedure were of the slightest. At the time of operation (on Oct. 1st, 1903) it was clear that so much tissue would have to be sacrificed that great difficulty would be experienced in closing the abdomen. A silver wire filigree was therefore made after the method suggested and practised by Willard Bartlett, measuring five inches by two and a half inches, and this was inserted between the muscles and the peritoneum, the former being approximated by the introduction of a special form of removeable deep suture. The skin incision was then closed by interrupted silkworm gut sutures and a firm abdominal binder was applied. Both superficial and deep sutures were removed by the tenth day and the patient left the hospital at the end of three weeks. Since the operation she had been well and comfortable in every respect and was performing her ordinary duties without the use of an abdominal support of any sort The site of operation was sound, a firm and somewhat depressed area marking the position of the filigree. The whole of the symptoms previously complained of by the patient—viz., griping pain, nausea, frequency of micturition, and constipation—had entirely disappeared.—Mr. BRUCE CLARKE inquired as to the exact method of fixing the wire filigree —Mr. BARKER remarked that the interlacing of sutures at the time of the operation took longer but in his belief gave very good, if not better, results. Such cases wanted following up for several years.—Mr. MCGAVIN replied and described the method of making and fixing the filigree or lattice-work of wire.

OPHTHALMOLOGICAL SOCIETY.

Indirect Gunshot Injury of the Eye: Microscopical Examination.—An Easy Operation for Ectropion.—Average Visual Acuteness.—The Judgment of the Size of Distant Objects — Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on Nov. 19th, Mr. JOHN TWEEDY, the President, being in the chair.

Mr. E NETTLESHIP read a paper on a case of Indirect Gunshot Injury of the Eye with Microscopical Examination The patient was a youth, aged 19 years, who in July, 1897, held a pistol to each temple and fired. He was taken to the hospital bleeding from a wound in the right temple. The skin was singed and the bullet wound passed through the orbit into the ethmoid. In the left temple was a bullet wound into which a probe could be passed two or three inches. There was perception of light in the right eye but not in the left. Nine days later the right fundus showed hæmorrhages in various parts of the fundus. In the left no details were visible. 29 days later the right disc was very pale and there were several ruptures of the choroid. The left was not so well seen. 31 days after the accident he was examined with the x rays, this being in their very early days. It was thought that two bullets were seen in the skull but this was found afterwards to be an error. On the thirty-sixth day after the injury convulsions developed and the patient died comatose. Post-mortem examination showed that there was no bullet in the skull. There was meningitis of the base and vertex. Only the pistol fired on the left side took effect, the right having probably had a blank charge in it. The back part of the eyes were removed for examination and Mr. Nettleship gave a lantern demonstration and showed photographs of the condition found on microscopical examination. The point of interest was that although the bullet had caused so much injury to the choroid yet this was only indirect as it had not passed near enough to the eye to touch it and there was no rupture or perforating injury of the sclerotic.—The PRESIDENT mentioned a somewhat similar case that had come under his own observation.

Dr. A. FREELAND FERGUS described an easy Operation for Ectropion which he had found very useful for ectropion following certain cases of blepharitis. He considered that the usual methods with caustics were unsatisfactory. The operation he described consisted of dissecting the conjunctiva well away from the underlying tissue and removing the hypertrophied tissue thoroughly; on this latter point depended the success of the operation. He considered that Snellen's sutures produced but little effect if they were kept aseptic.

Dr. FERGUS also read a paper on Average Visual Acuteness He seriously called in question whether the $\frac{6}{6}$ of Snellen's types was the average vision of the majority of people. He thought that the average was nothing like so high if patients were taken without the correction of their refractive error, and that for medico-legal questions the average without correction should be taken. He requested that a committee should be formed to investigate this. It might at the same time investigate the question of colour vision, as he considered that colour blindness was not in any way dangerous to navigators or seamen if their light sense were normal. —Mr. C. DEVEREUX MARSHALL said that he was surprised that colour blindness should be considered of so little importance to those engaged in navigation, and if there were any who doubted the extreme inadvisability of allowing colour blind men to take responsible positions on board ship a committee should certainly be formed to settle the matter —The PRESIDENT said that although he quite agreed as to the importance of the light sense being perfect, yet he by no means thought that colour-blind people should be allowed to take charge of ships —Mr. H. SECKER WALKER and Mr. W. G. ROLL discussed the operation, and Dr. FERGUS, in reply, said that he considered colour blindness of no disadvantage to seamen, for if their light sense was perfect they would never confuse the side lights. He thought it entailed much hardship on men who were perhaps refused the extra master certificate for colour blindness when they may have served many years at sea without any accident having occurred in consequence of their defect.

Mr N BISHOP HARMAN, in a paper on the Judgment of the Size of Distant Objects, referred to a note in the *British Medical Journal* of Sept. 12th, 1903, wherein a writer drew attention to an experiment in which, by an illusion, the experimenter was led to believe objects seen were smaller and more distant than they were known to be; this had been attributed to the influence of accommodation. Mr. Harman pointed out that these facts were true and well known. He showed by several simple experiments with prisms and stereoscopic views that objects could be made to appear either small or large at will and that this illusion was due to the state of balance of the extra-ocular muscles. The unconscious cerebration led the observer to suppose that objects of a given size appeared, when seen under unnatural conditions of convergence, smaller and more distant, but that when seen under unnatural divergence they seemed larger and nearer than they were known to be. Mr. Harman showed that in the progression of the vertebrates increase of visual acuity was coincident with the moving of the eyes from a primitive lateral position in the head to a forward position in which the visual axes could approximate a normal parallelism; the change was complete in man and with him special perception was probably most perfect. Coincident with these changes was a specialisation of the superior oblique muscle. Mr. Harman pointed out that in the plaice almost the whole of this slow progression had been anticipated at a bound. This fish elected to live a life resting on one side and it appeared to depend above all other fish on the acuity of its eyes, both of which were turned upwards on the exposed uppermost side and were, he thought, capable of some degree of parallelism of visual axes. In this fish he had found the same special features of the superior oblique muscles which characterised the higher vertebrates; they were not found in any other than flat-fish and not even in the embryo forms of these. He believed that the steady progression of the vertebrates towards binocular vision indicated the pre-eminent importance of extra-ocular muscle balance in the factors which went to form their judgment of size and space.

The following cases and card specimens were shown:—

MR. ROLL: A case presenting a raised area of Choroidal Degeneration.

MR. R. W. DOYNE: (1) A case of ill-developed Cornea; and (2) Sclerosis of the Retinal Arteries.

MR. G. H. POOLEY: Thrombosis of a Retinal Vein (?).

MR. E. E. HENDERSON: Sections showing Subconjunctival Dislocation of the Lens.

MR. W. H. H. JESSOP: A case of Sarcoma of the Limbus.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

Election of Officers.—Treasurer's Report.

AT the annual general meeting, held on Nov. 23rd at St. Mary's Hospital, Mr. C. B. LOCKWOOD, President, in the chair, the following officers were elected for the ensuing year:—President: Dr. J. Symington. Vice-Presidents: Dr. A. Thomson, Dr. A. M. Paterson, and Dr. J. Yule Mackay. Treasurer: Mr. F. G. Parsons. Secretaries: Dr. Peter Thompson (England), Dr. R. J. A. Berry (Scotland), and Dr. R. A Stoney (Ireland). Council: Dr. C. Addison, Dr. A. Birmingham, Dr. T. H. Bryce, Dr. D. J. Cunningham, Dr. A. F. Dixon, Dr. E. Fawcett, Dr. R. J. Gladstone, Dr. T. Wardrop Griffith, Professor G. B. Howes, Dr. A. Keith, Mr. C. B. Lockwood, Dr. A. Macalister, Dr. J. Musgrove, Dr. C. J. Patten, Mr. W. G. Ridewood, Professor A. Robinson, Mr. G. D. Thane, Mr. H. J. Waring, Dr. B. C. A. Windle, and Dr. A. H. Young.

DR. A. KEITH (in the absence of Professor G. B. Howes) presented the treasurer's report for the year. The accounts showed a balance of £55 14*s.* 2*d.*, which, in view of the increased expenditure in illustrations and printing for the society's Proceedings during the last session, must be considered as very satisfactory.—The PRESIDENT, in moving the adoption of the report, referred to the long years of service which Professor Howes had devoted to the society as its treasurer and he *proposed "that the best thanks of the* society be accorded to Professor G. B. Howes for the long and valued services which he has rendered in the capacity of honorary treasurer."—This was carried unanimously.

The following gentlemen were then elected members of the society:—*Dr Waterson, Mr. W. Thorburn, Mr F. H.* Westmacott, Dr. C. W. S. Saberton, Dr. W. Harris, Mr. H. S. Clogg, Dr. E. J. Evatt, and Mr. Scott.

The following papers were afterwards brought before the meeting:—

MR. PARSONS: (1) On the Nature of Certain Epiphyses; (2) On the Fascial Expansions of the Gracilis and Semitendinosus.

DR. W. KIDD: Notes on the Eyebrows of Man.

DR. KEITH: A note on the Nature and Functional Meaning of the Ileo-cæcal Valve.

DR. W. HARRIS: The True Form of the Brachial Plexus.

DR. J. CAMERON (communicated by Dr. Peter Thompson): On the Presence and Significance of the Superior Commissure *throughout the Vertebrate Series.*

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Sheffield on Nov. 20th, Dr. J. E. Gemmell, the President, being in the chair.—Dr. T. B. Grimsdale read notes of a case of Sloughing Submucous Fibroid of the Uterus projecting through the Cervix treated by abdominal hysterectomy. The specimen was also shown.—The President Dr. W. Walter, Dr. D. Lloyd Roberts, and Dr. E. C. Croft discussed the case. —Dr. R Favell read notes of a case in which a vesicular mole was passed the day after admission to hospital by a married woman, aged 21 years, in her third pregnancy. Two small purplish growths of the size of raspberries were excised from the anterior vaginal wall. Exploration of the uterus showed that the mole was of the destructive variety. The patient made a good recovery. He also read notes of a case of Submucous Fibroid removed from a married woman, aged 33 years, who had no children and who suffered from a watery discharge and menorrhagia.—The President and Dr. Lloyd Roberts suggested that the second case seemed to be a favourable one for performing "Cæsarean section" of the fibroid, the latter holding that this was perfectly justifiable in a woman in the child-bearing age, but in a woman of 50 years it did not appear necessary. —*Dr.* Walter said that when it was possible he always removed fibroids by enucleation or by a sort of Cæsarean section. Although his experience in nearly every case was that the uterus was so bruised by this that it became a question whether it was worth while preserving, yet the operation should always be begun with the hope of saving it. —The President read notes of a case of Complete Occlusion of the Os Uteri Externum at Full Term. The patient was a *primipara who had been 12 hours in labour. There had been* some hæmorrhage which proceeded from a vaginal laceration on the left side; there was no trace of an os but a cystic swelling bulged into the roof of the vagina and in this the fœtal head was felt. The patient was admitted into the Lying in Hospital in a collapsed condition. On examination a white spot of the size of a pin's head was found on the left of the swelling and a crucial incision was made through it. The child was delivered with forceps, incision of the perineum being necessary. Subsequently the temperature rose and local examination proving negative, antistreptococcic serum was given. After slow convalescence the patient left the hospital. It was pointed out that such an occlusion was not always the trivial matter which it was generally *regarded as being. Mattei, in a collection of cases, showed* 36 operations out of 42 cases, with three maternal deaths.—Dr. Lloyd Roberts mentioned two cases which had occurred in his experience.—Dr. Croft read a paper on three cases of Urinary Calculus in the Female. In the first case a stone weighing five grains was passed spontaneously per urethram. The second calculus weighed 232 grains and was removed by vaginal cystotomy from a woman, aged 62 years. The same treatment resulted in the third case in the removal of a stone 510 grains in weight from a woman, aged 20 years. Dr. Croft thought that in all three cases the calculi had their origin in the *kidney and he emphasised the necessity* for removing stones of such size by a vaginal incision in [illegible] or perform- [illegible] it he thought [illegible] he preferred to place a tube in it and to drain for a week before allowing spontaneous closure to take place In a small vagina this saved trouble.—Dr. Walter said that he agreed with Dr. Croft's remarks as to the route adopted and considered that even exploration of the bladder per urethram by means of the finger was unsafe.—Various pathological specimens were shown by Dr. John W. Martin and Dr. Walter.

ABERDEEN UNIVERSITY MEDICAL SOCIETY.—A meeting of this society was held on Nov. 27th, Professor J. T. Cash being in the chair.—Dr. D. Lawson of the Sanatorium, Banchory, delivered an address on the Sanatorial Treatment of Pulmonary Tuberculosis, commencing his remarks with a reference to the historical side of the subject. He said that in 1840 Mr. *George Bodington of Sutton Coldfield published* an essay on the Cure of Pulmonary Consumption on Principles Rational and Successful and established a sanatorium which was eventually converted into an asylum for the insane. In 1855 Dr. Henry MacCormac of Belfast published his work and was afterwards censured for wasting the time of his colleagues. Hermann Brehmer in 1856 wrote a thesis entitled "Tuberculosis in its First Stage is always Curable" and in 1859 he opened the Goerbersdorf Sanatorium. Among those who were authorities on the subject of present-day sanatoriums there were three clearly defined schools—the Falkenstein, the Nordrach, and the British school. At the Falkenstein Sanatorium there was one central building with wings *forming* an obtuse angle with it and a prominent feature of the treatment was the rest in the open air which was enforced amongst the patients. With regard to food patients were allowed considerable liberty and, generally speaking, ease, comfort, and luxury prevailed. The Nordrach Sanatorium consisted of a colony of detached buildings. Regulated exercise was largely employed in the treatment of patients and forced feeding to a certain extent formed part of the system. The *régime* was of the Spartan kind and in contrast with the one at Falkenstein Sanatorium; there were no billiard or smoking rooms in connexion with the Nordrach establishment. Both Falkenstein and Nordrach sanatoriums were defective in regard to the scientific side of the treatment and neither of them was provided with a sufficient nursing staff according to the ideas which prevailed in this country. The British school aimed at combining the recognised good points of both these establishments and at providing a fully qualified nursing staff, first-class equipment upon the scientific side, a relatively large medical staff, and individual treatment. The Banchory Sanatorium followed the precedent of Falkenstein to the extent that it was one central building and that it provided facilities for the patients lying out in the open air. Although there were some differences of opinion in the British school with regard to architectural arrangements, practically all were at one in dispensing with billiard rooms, smoking rooms, and conversation rooms, and in this respect they resembled Nordrach. At the Banchory Sanatorium considerable attention was given to the scientific side of the question and there were research laboratories and various kinds of scientific appliances, including x-ray apparatus. Dr. Lawson then described the system of treatment which was followed. With regard to walking exercise he said that at first the distance was probably not more than 100 or 200 yards, but it was gradually increased until by the time the patient was discharged he might be walking about 30 miles a day. There were no set rules as to exercise; that had to be regulated by various things such as the temperature of the patient. The advantages of hill-climbing in connexion with the treatment were very great owing to the tendency to deep breathing which was promoted.

Sheffield Medico-Chirurgical Society.—A meeting of this society was held on Nov. 19th, Mr. G. H. West Jones, the President, being in the chair.—Dr. A. J. Hall showed four cases, one of which was an example of Thrombosis of the Portal Vein in a man, aged 48 years.—Dr. W. T. Cocking showed a man, aged 36 years, the subject of Progressive Myositis Ossificans. The disease, which was very advanced, commenced at the age of eight years and during the last few years the patient had been an inmate of many London and provincial hospitals. The case is reported by Dr. H. D. Rolleston in the Transactions of the Clinical Society, vol. xxxiv., and in The Lancet of Sept. 28th, 1901, p 849, by Mr. A. Ll. Vaughan.—Mr. G. Wilkinson showed a man, aged 37 years, from whom he had removed a retroperitoneal lipoma weighing 13 pounds 12 ounces six weeks previously. The growth had to be separated from the bladder and the right ureter was found running through the mass and was dissected out for about eight inches of its course. The patient suffered from shock for 24 hours after which he made a speedy and uneventful recovery. The tumour measured 19 inches in length by 12 inches in breadth and about six inches in thickness.—Other cases were shown by Mr. Edward Skinner, Dr. F. H. Waddy, and Dr. A Cuff.—Dr. A. Lewis Husband read a paper on Agoraphobia and some allied conditions. After defining the three conditions known as agoraphobia, claustrophobia, and acrophobia, he related cases which he had met with during a period of seven years. In all some 40 cases had been collected. After discussing the probable etiology of the conditions from the optical, physiological, anatomical, and psychical standpoints he drew the following conclusions. 1. Agoraphobia, claustrophobia, and acrophobia are more or less allied conditions attributable to analogous causes. 2. Agoraphobia and claustrophobia are directly determined by errors in the visual apparatus, chiefly refractive. The former is usually associated with myopia and the latter with hypermetropia. Astigmatism and asthenopia may be associated with either. 3 Acrophobia is generally due either to lack of training and experience in the visual measurement of distance in the downward direction or to loss of acquired power sequential to some condition of lowered vitality, such as anæmia, neurasthenia, or senility. 4. Agoraphobia and claustrophobia, but not acrophobia, are most common in persons of neurotic temperament and tendencies. 5. Neurasthenia and similar affections do not necessarily cause any of these conditions, nor are the latter always characteristic of neurasthenia, but neurasthenia plus refractive errors usually causes either agoraphobia or claustrophobia. 6. All the conditions become much exaggerated under any low state of health.

Windsor and District Medical Society.—A clinical meeting of this society was held at the Guildhall, Windsor, on Nov. 25th, the President, Mr. W. B. Holderness, being in the chair. Various microscopical specimens were exhibited, and through the kindness of Dr. Butcher Mr. J. Startin was enabled to show to the members a specimen of Radium and mentioned its good effects in the treatment of rodent ulcer.—The President showed a case of extensive Lupus of the Face and Upper Extremities in places simulating psoriasis. The patient had undergone treatment in London by the Finsen light and had derived considerable benefit but was now unable to continue the sittings.—Mr. Startin exhibited a patient who had been under the care of Mr. A. C. Wigmore and himself. The patient, a young man, presented some scarring of the cheeks, where an extensive patch of lupus had been cured by the persistent application of the Roentgen rays.—Mr. J. H. Tomlinson showed a man, aged 45 years, the subject of Facial Paralysis and Choroiditis. He suffered from subjective visual sensations of an unusual nature.—Dr. G. E Hale showed a case of a Pulsating Expansile Tumour in an elderly woman. It was thought to be an aneurysm of the abdominal aorta or of the cœliac axis.—Dr. W. F. Lloyd showed (1) a case of Lupus of the Upper Lip in a young woman (treatment by the application of the x rays had been tried and so far there had been little result); and (2) a case of Leucoplakia of the Tongue in a woman aged 55 years.—Dr. F. E. Wood showed (1) a woman, aged 56 years suffering from Dilatation of the Capillary Vessels over the Chest, Abdomen, and Arms (there was hypertrophy of the heart, arterial fibrosis, and albuminuria); and (2) a boy, aged 12 years, with Two Systolic Murmurs, one of which was thought to be congenital.—Dr. C. R. Elgood showed (1) a woman, aged 50 years, the subject of Raynaud's Disease; and (2) a child with Unequal Pupils, the larger being insensible to light and to accommodation.—The cases were subsequently discussed *seriatim*.

Plaistow and Canning Town Medical Society.—A meeting of this society was held on Nov. 26th, Mr. Percy Rose being in the chair.—Dr. P. Horrocks, who was present by special invitation, read a paper on Puerperal Sepsis. He discussed the subject from the standpoints of causation, prevention, and treatment. Among the sources of infection he was of opinion that streptococcal contagion from other cases of septicæmia, from cases of erysipelas, and from decomposing animal matter such as was found in post-mortem rooms and butchers' shops, played the most important part As regards prevention he laid special stress on the careful sterilisation of the accoucheur's hands, the avoidance of frequent vaginal examinations, and the abstention from intra-uterine and vaginal douching except in cases already infected. In the treatment of puerperal sepsis intra uterine douching was certainly of value, particularly in cases of sapræmia. A more thorough method was curetting the whole of the uterus. He did not approve of hysterectomy in such cases. Antistreptococcic serum was sometimes of value but it frequently failed.—An interesting discussion followed the reading of the paper.

Æsculapian Society of London.—A meeting of this society was held on Nov. 27th, Dr. Leslie Durno, the President, being in the chair.—Dr. David Ross read a paper on Visceroptosis based on a case of dropped liver in a multipara, aged 37 years. She had for six months severe paroxysmal pain at the region of the liver that sometimes commenced in her sleep, lasted one or two hours, and then passed off. She was so fat that though the lump below the right ribs could be felt a diagnosis was uncertain. But as she became thinner the liver could be taken between the two hands above and below and a diagnosis made. A belt was worn which completely prevented symptoms. 40 ounces of urine were passed per diem; it had a specific gravity of 1012, no albumin was present, and it contained 0·4 per cent of glucose.—Mr. F. Hewitt Oliver reported a case of Fatal Carbolic Acid Absorption by a baby who was circumcised, the wound being dressed with 1 in 40 of carbolic acid for four days; in that time 15 ounces of a 2·5 per cent. solution were used. Then the child became collapsed and died shortly afterwards. Acute nephritis was found by a microscopic examination of a kidney.

Chelsea Clinical Society.—At a meeting of this society, held on Nov. 17th, Dr T. Vincent Dickinson, the President, being in the chair, Dr. C. O. Gibbes showed a series of cases illustrating the Effect of Overstrain on the Orifices and Walls of the Heart and Aorta.—Dr. Vinrace exhibited a Dermoid Cyst, consisting of sebaceous matter and hair, which was found unexpectedly during a post-mortem examination on a woman, aged 29 years.—Dr T. B. Hyslop read a paper entitled "The Examination of a Person Alleged to be Insane."—Dr. Eric Pritchard read a paper on the Inheritance of Acquired Characteristics. He contended that certain acquired characteristics must be inherited. The inheritable characteristics were those which were due to general changes of metabolism in the parent, such as immunity and susceptibility to disease. Inasmuch as the germ plasma is living it must have a metabolism and this can be altered by the factors in the environment. If habits of metabolism can be inherited, since structure is one of the expressions of metabolism, it is at least theoretically possible that acquired morphological structures may in certain cases also be inheritable.

Newport Medical Society.—A meeting of this society was held on Nov. 25th, Dr. J. Howard Jones, the President, being in the chair The following clinical cases and specimens were exhibited. Patients with Locomotor Ataxy, Tertiary Syphilitic Ulceration of the Nose and Lupus under Treatment by Roentgen Rays (four cases), and sections of Melanotic Carcinoma and of Adenoma.—The President delivered an address on Hygiene Ancient and Modern, in which he described the hygienic measures prescribed for the Jews in the Mosaic laws and the Talmud and compared them with our modern public health regulations.

Reviews and Notices of Books.

An Atlas of Human Anatomy for Students and Physicians. By CARL TOLDT, M.D., Professor of Anatomy in the University of Vienna; assisted by ALOIS DALLA ROSA, M.D. Translated from the third German edition and adapted to English and American and international terminology by M. EDEN PAUL, M.D. Brux., M R C.S. Eng., L.R.C.P. Lond. First Section: A. The Regions of the Human Body; B. Osteology. Figs. 1 to 377, and Index. London: Rebman, Limited. 1903 Pp. 160. Price 9s. net.

ENGLISH-speaking students of anatomy will not fail to appreciate the excellent translation of the first section of Toldt's Anatomy which has been prepared by Dr. Eden Paul. This atlas has advowedly been selected on account of its claims to be an accurate pictorial representation of all the data of human descriptive anatomy carefully drawn to scale from actual specimens. As the translator observes, it forms a definite and systematic application of the visual, or rather graphic, method to anatomical study. This claim is good and sound and the volume before us fully bears out all that is claimed for it.

It is, perhaps, hardly fair to call the work a mere translation; thanks to the care and industry of the translator it is more than this. It really affords a direct tabular comparison of the English and continental terminology. The translator very justly deplores the absence of a universal anatomical nomenclature which should be equally intelligible to students of all nationalities. Difficulties and defects in nomenclature have evidently formed the chief obstacle in translation and appear to have been admirably surmounted. The continental and English names are in all cases printed side by side on the illustrations in distinctive types. In selecting the appropriate English equivalent much discrimination has been exercised and Quain's and Macalister's works have been mainly adopted as standards. The translator points out that in some places the author's nomenclature actually conflicts with that in use in England as, for instance, in the case of the pterygo palatine canal, a term which is applied to what we know as the posterior palatine canal, whilst our pterygo-palatine canal becomes pharyngeal in his nomenclature.

The first section of the atlas is devoted to the names of regions of the body and to osteology. The former is naturally brief and calls for no detailed notice. The osteological section is very full and the majority of the illustrations are admirable and very faithful representations of the various bones. In the case of a few of the smaller bones of the face and carpus the illustrations leave something to be desired; if drawn on a larger scale they would probably have been more distinct and of greater educational value.

A very useful feature of the atlas is the attention which is given to the development of the various bones. This is fully illustrated with drawings from nature taken at various ages and forms to our mind one of the distinctive features of the atlas. By comparing these drawings with the statements given in the various text-books the reader gains some idea of the wide variations in the time of appearance of the individual centres of ossification. Care has been taken in every case to impress the fact that in continental nomenclature the term "month of fœtal life" indicates a period of four weeks and not a calendar month as with us. The atlas is of handy size (8½ × 11½ inches) and is not unduly heavy. It forms a useful supplement to any of the ordinary text-books of anatomy.

Handbook of Surgical Anatomy. By G. A. WRIGHT, M.A., M.B Oxon., F.R.C.S. Eng., Professor of Systematic Surgery in the Owens College; Surgeon to the Manchester Royal Infirmary, &c.; and C. H. PRESTON, M.D., B S Lond, F.R.C.S., L.D S Eng., Lecturer on Dental Anatomy in the Owens College; Assistant Dental Surgeon to the Victoria Dental Hospital of Manchester. London and Manchester: Sherratt and Hughes. 1903 Pp. 202. Price 4s. 6d net.

Dr. Wright and Dr. Preston have produced a concise and very readable little handbook of surgical applied anatomy. They are careful to disclaim any originality in the matter contained but have evidently made a careful selection of the more important anatomical facts having a direct bearing upon surgical practice. One section of the book, however, does appear to be a new departure in volumes of this sort: an instructive series of facts in dental anatomy is included. The reason given for this addition is the fact that medical and dental students receive much of their anatomical instruction together at the Manchester School. We should like to see a similar section in all books on applied anatomy; it would be profitable to all readers. The subject matter of the book is well arranged and the marginal notes in bold type facilitate reference to any desired point. The order adopted is upper extremity, neck, face, head, teeth, thorax, back, abdomen, perineum, pelvis, and lower extremity. All parts are as fully dealt with as could be expected in a book of this size. There are one or two obvious slips. The nerve-supply of the palmaris brevis is said to be from the median but this is not so serious a mis-statement as the information that the lowest six dorsal nerves arise between the fourth and first lumbar spines. Surely this should read "between the fourth and ninth dorsal spines." The name of Landrevt associated with the paraduodenal fossa is a misprint for Landzert. We have heard of Sylvia but not in connexion with a fissure of the cerebrum. The ascending parietal convolution is still credited with motor functions and the sigmoid flexure is described in the old and very misleading way. Reference is made to removal of the prostate but the anatomy of the process receives the scantiest attention, which is a pity. We should like to see some warning of the frequent variations of the brachial artery. On the whole, however, the book is trustworthy and well worth perusal.

Atlas der Deskriptiven Anatomie des Menschen. (Atlas of Human Descriptive Anatomy.) By Dr. J. SOBOTTA, Professor of Anatomy in the Anatomical Institute at Würzburg. First Section: Bones, Ligaments, Joints, and Muscles. With 34 Coloured Plates and 257 Coloured Illustrations by K HAJEK and A. SCHMITSON. Munich: J. F. Lehmann. 1904. Pp viii. + 229. Price 20 marks.

Grundriss der Deskriptiven Anatomie des Menschen. (Essentials of Descriptive Anatomy.) First Section: Bones, Ligaments, Joints, and Muscles. By the same author. Munich: J. F. Lehmann. 1904. Pp. 207. Price 4 marks.

THE atlas is the second volume of Lehmann's series of medical atlases. It fully maintains the high level of excellence attained by the first atlas which was devoted to topographical and applied anatomy. The present volume is the pioneer of a series of three illustrating descriptive anatomy and contains figures of the bones, the joints, the ligaments, and the muscles of man. The number of plates and illustrations is very large and they are all of a satisfactory size. A short description is attached to each figure in the atlas and in addition in the accompanying volume of Essentials of Descriptive Anatomy a more detailed and systematic account of the structures illustrated is to be found. The illustrations are all of great merit and many of them are very beautiful reproductions in colour; most are very true to nature and are exceedingly useful in reviving a visual image of parts and their relations. We have no doubt that the Atlas and Essentials together will be found very useful by those desirous of revising their knowledge or of refreshing their memories of the more salient anatomical facts. Naturally, in such a work as the Essentials the author does not profess to go into minute details but deals with the broad facts of descriptive anatomy only. This object he very successfully achieves; therefore it is for revision and for revision only that we recommend the work. The artists are to be cordially congratulated on the result of their labours and the publisher on having the enterprise in issuing so fine an atlas at a moderate price.

LIBRARY TABLE.

The Refraction of the Eye: A Manual for Students. By GUSTAVUS HARTRIDGE, F.R.C.S.Eng. Twelfth edition. With 105 Illustrations. London: J. and A. Churchill. 1903 Pp. 266. Price 6s.—Mr. Hartridge's modest treatise is rapidly becoming a portly volume and certainly now contains all that the ordinary practitioner and even the specialist need know in this department, unless he is desirous of following out the subject of refraction into details which demand a thorough knowledge of mathematics. As it was one of the first in the field and has run through 11 editions, Mr. Hartridge has been able to correct the trifling defects that were present in the first edition, to weed out unimportant statements, and to expand those that his more mature experience has taught him are often misunderstood by students. The chapter on retinoscopy is written in a particularly clear and intelligible style and gives many examples which, if comprehended, will guide the practitioner to the appropriate treatment of analogous cases.

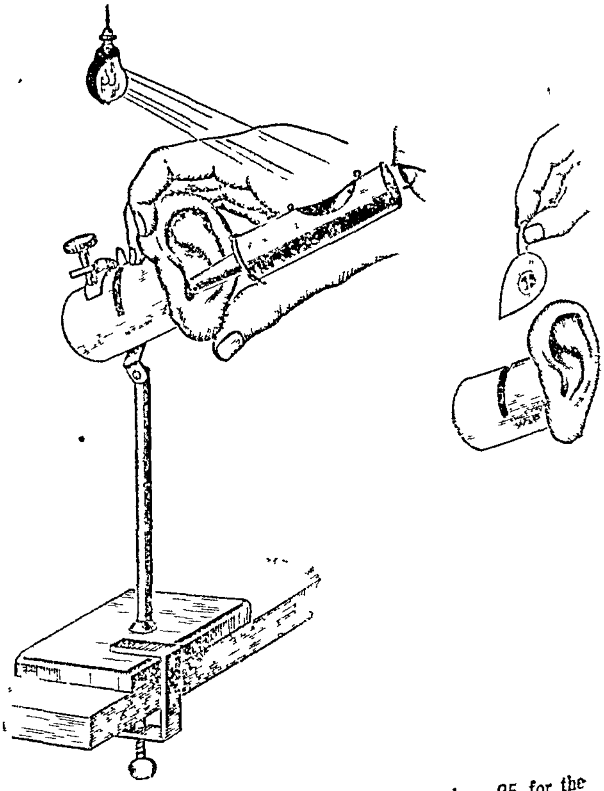
The Practical Details of Cataract Extraction. By H. HERBERT, F.R.C.S.Eng., Major I.M.S. Second edition. London: Baillière, Tindall, and Cox. 1903 Pp. 114. Price 4s. net.—We have so recently had occasion to call attention to Major Herbert's work which gives the results of his large Indian experience that it is unnecessary to say more than to congratulate him upon so speedy a demand for a second edition. The number of operations from which he draws his conclusions is far in excess of that which falls to the lot of most European surgeons, for in the short space of one year and seven months Major Herbert performed 1374 extractions (linear operations excluded). Amongst all these chloroform was only employed twice. The details of the method adopted with extraordinary success by such an operator must needs be worthy of careful study.

Christmas and New Year Greeting Cards.—A varied assortment of these souvenir cards has reached us from Messrs. Raphael Tuck and Sons, of Moorfields, London, E.C. Their productions this season comprise some 1600 new varieties all of which are beautiful in design and appropriately worded. The demand for cards of friendly greetings has increased year by year largely in consequence of the artistic effects now to be obtained by the developments of the photographer's and colour printer's technics, and Messrs. Raphael Tuck and Sons have been quick to use these developments in their manufactures.

New Inventions.

A NEW MODEL EAR FOR THE STUDY AND PRACTICE OF OTOSCOPY.

THE accompanying illustration shows the form of a new model ear constructed by Mr. F. Davidson 140, Great Portland-street, W. It is made of a composition which lends itself to the necessary manipulation. A slit is cut in the wall of the meatus, so that the discs on which the lithographic reproductions of the drawings of different conditions of the drum membrane are mounted can be readily inserted. The series of illustrations comprises 25 for the right and 25 for the left and are of perforations, retraction, inflammatory and other conditions. The brass stand, which is hinged to allow of the model ear being tilted to any desired angle, is fixed by a clamp to a table and examination can be made exactly as with the human ear. The drawings have all been done by Mrs. Davidson.



J. B. BALL, M.D.,
Physician to the Ear and Throat Department of the West London Hospital.

THE LANCET.

LONDON: SATURDAY, DECEMBER 5, 1903.

The General Medical Council and the Royal Colleges of Physicians of London and Surgeons of England.

IN the interest of peace it is, perhaps, a source of congratulation to all concerned that after the most prolonged discussion of the General Medical Council's recent session no definite conclusion was reached. The subject of consideration was the lamentable difficulty that has arisen between the General Medical Council on the one hand and the Conjoint Board of Examination, representing the Royal College of Physicians of London and the Royal College of Surgeons of England, on the other hand, and the point at issue is the power of the General Medical Council to control in any true sense the regulations which those Colleges may make for the courses of study and the examinations which are conducted by them. The matter has been repeatedly brought before our readers during the last few years and it will be remembered that the dispute turns upon the regulations and examinations in chemistry, physics, and biology, the subjects which were intended wholly, or in large part, to occupy the first year of the medical curriculum. The complaint of the General Medical Council is twofold. In the first place, it is urged that by the recognition of schools as places of study only a small amount of time is really occupied with scientific studies and that these are often pursued in circumstances which do not entitle them to respectful consideration, and secondly, that the examinations do not suffice to exclude those who only possess "an empirical knowledge of a few facts crammed up from a book or a teacher" and who have "no understanding of elementary principles." These strong comments are extracted from the report of the visitor and inspector appointed by the Council and they receive confirmation from further returns which have been supplied to the Council by the Secretary of the Conjoint Board. The conclusions inevitably forced upon the Council are that the regulations of the Colleges are injurious to the best interests of medical education in this country, and that by recognising the teaching of these scientific subjects in secondary schools, higher-grade Board schools, municipal technical schools, and polytechnic institutions as well as in the medical schools, the first year of medical study is practically wasted. This opinion has repeatedly been brought before the Colleges by the General Medical Council and in view of the inaction of these bodies Sir VICTOR HORSLEY gave notice last June of his intention to move that the insufficiency of the courses of study and examination should be represented to the Privy Council in accordance with the terms of the Medical Acts.

This motion was brought forward at a special meeting of the General Medical Council early in July last, but it was withdrawn in favour of the appointment of a committee of two members from each of the three Branch Councils to confer with representatives of the Colleges, should it appear that a conference on the questions raised thereon was desired. Doubtless this proposed committee was intended to afford the Colleges an opportunity of reaching some common ground of agreement, but all hopes in this direction were frustrated by the refusal of the Colleges to appoint representatives, which was equivalent to a politely expressed determination to manage their own affairs, while allowing that the opinions of the Council should receive respectful attention. Sir VICTOR HORSLEY accordingly proposed his motion to report to the Privy Council so as to bring about a decision as to who was the supreme authority in medical education. His speech was marked by a freedom of expression which doubtless alienated the sympathy of many. It was unfortunate that reference was made to the "authority of the Council," since this afforded Dr. NORMAN MOORE, the representative on the Council of the Royal College of Physicians of London, an opportunity to leave the question at issue—the examinations in biology, chemistry, and physics—and to direct attention to the charters and responsibilities of the two Colleges, under which he claimed that responsibility rested with the Colleges and the right of criticism with the Council. An amendment, which was couched in extremely friendly terms, suggested that the Council should defer taking further action pending the promised reconsideration of the whole subject by the Colleges and the re-inspection of their reconstructed examinations. This amendment was carried but on becoming a substantive motion it was met by a proposal that the motion be postponed and this was carried by one vote only. The present position, therefore, is that the Colleges are considering the subject, hoping to remedy all defects, so that there is some prospect of the formulation of new regulations before the Council's meeting in May. Meanwhile an open rupture has been averted and the Council has shown its determination to maintain the position which it has taken up.

Viewed from the outside the whole turmoil is much to be regretted. Neither the Council nor the Colleges can gain by futile discussions on authority or contumacy, responsibilities or charters. The common aim of all should be the elevation of medical education. The numbers of candidates presenting themselves for examination in chemistry and biology at the Conjoint Board have shown a very remarkable decrease during the last ten years, and during the last few years the numbers trained in science institutions (the term being used in contra-distinction to the medical schools) have shown a slight increase. Still, these last fall numerically far below those educated in the medical schools; for the ten years they do not amount to 7 per cent. These figures are important, since the present deadlock originated in a protest against the recognition by the Colleges of many teaching institutions which were not approved by the Council, and it is interesting to find that such "recognition" has not yet seriously influenced the medical schools. If, in spite of the fact that the numbers receiving their preliminary scientific education in institutions other than medical schools are very small, the examinations really merit the strong condemnation of the visitor and inspector appointed by the Council, it would appear to be fair to assume that *the teaching, which is guided* by the character of the examinations conducted by the Colleges, must be very defective. The Education Committee of the General Medical Council does not hesitate to blame the synopses of the examinations in chemistry, physics, and biology, which in the opinion of the committee do not afford adequate guidance to the teachers as to the course of study best suited to the needs of medical students. It is to be hoped that before next May amended synopses in these subjects will be prepared and that the Colleges will seriously consider whether it is wise to continue to recognise courses of study which are conducted synchronously with ordinary school work. Many of the London medical schools undoubtedly object to the necessity of maintaining teachers and laboratories for these subjects, and in some institutions want of space forms a serious obstacle to class and laboratory work; but although these arguments are cogent they should not be allowed to reduce the utility of the first year of medical studies. Still less should such considerations be permitted to account for the presentation to the medical profession and to the public of discussions which, whether termed quarrels, differences of opinion, or friction, are deeply to be deplored.

◆

The Employment of Children Act.

THE Employment of Children Act, 1903, which will come into operation on Jan. 1st, 1904, is a measure the scope and complexity of which are equalled by the importance to the nation of the subject with which it is concerned. Its general outline is simple as becomes its practical character. It provides that no child may be employed in work for wages under 11 years of age. Between the age of 11 and 14 years labour is allowed under regulations. The statutory working time must come within the hours of 6 A.M. and 9 P.M. No employment which is believed or proved to be injurious to the individual may be carried on. A significant feature in the Act is the large discretionary powers which it places not without deliberation in the hands of local authorities. They may vary working hours, grant or withhold licences to children, restrict or entirely prohibit street-trading by girls, prohibit labour in other trades by children under 14 years of age, regulate employment in theatres and music-halls up to the same age, and generally supervise and administer the whole conduct of child labour within the districts under their control. The necessity for the effective protection of juvenile workers is brought out in a report published by the inter-departmental committee on the employment of school children. According to this paper at least 200,000 children are being employed for profit in occupations not under Home Office inspection while attending school for the full time. Very many of these, probably 50,000, are earning wages during more than 20 hours a week in addition to 27½ hours at school. A considerable proportion of this number are employed for 30, 40, and even 50 hours a week and the effect of this work has proved in many cases to be injurious to their health, morals, and education, apart from the fact that it deprives them of that due amount of recreation without which the life of a child is no better than a term of unwholesome drudgery. The committee has, therefore, embodied its conclusions in a series of propositions to the Home Secretary and the new Act may be regarded as the outcome of its representations. Certain of its suggestions have been particularly brought by the Act under the notice of local authorities. These include the licensing of all children employed for profit, the prevention of work injurious to health, including the moving of heavy weights, the question whether systematic labour of any kind or street-trading should be permitted at all during the ordinary school age, and the inadvisability of allowing girls at any age, and especially under 16 years, to trade in the streets. All the witnesses who gave evidence before the committee spoke forcibly as to the mischievous effects on character which result from the employment of girls in this way. Some other occupations are, in the view of the committee, also undesirable for children on the evidence of witnesses examined by it. Among these are service in public-houses, in small laundries, and in the lower class barbers' shops. The committee further proposes that the employment of children in any calling should never exceed 20 hours a week, of which not more than eight are on Saturday, and that work before school, during the dinner hour, and after 8 P.M., as well as all Sunday work, should be disallowed. Whatever may be thought of the Act and of the suggestive corollaries by which it is accompanied it is sufficiently clear that they have not been scamped or hastily thrown together. They show throughout the signs of reflection founded on experience. They do not ignore the possible advantages which have led to the systematic employment of children in this and other countries. They do not ask that it should be done away with. All that they require is that the benefit should be real and that it should not be all on one side. It must not be of that spurious variety which consists of nothing more than making children temporarily profitable to their parents and employers without regard to their physical well-being, their education, and their moral character. Alike from the domestic and from the national point of view the years from six or seven up to 14 are not properly wage-getting years. They are years of development. In this period the man or woman is made if ever to be made. If those years are diverted from their natural purpose there can only be one result—a weakening in bodily health, in intelligence, and in the sense of moral obligation which gives tone and fibre to the conduct of life. For this reason we are unable to see how any but light work and comparatively little of that can be expected of children during the school period. Their proper work is to be trained and to train themselves. The statutory hours devoted to this purpose fill in the greater part of a day. Then there are meal-times, a reasonable interval for recreation, and, we must add—and this is very often forgotten—time for the preparation of school lessons at home. There can thus be little more than an hour or so per day for wage-earning save perhaps on Saturday and we should be sorry to see the whole of that day applied to money-making labour. We have no idea of proposing any cast-iron regulations but we do think it necessary that local authorities and all others concerned should regard this business of training as quite the most serious consideration during the period allotted to it. Not even parental necessities are entitled in the nature of things to find systematic relief at its expense. To use it for this purpose would be a suicidal policy, inasmuch as education, which is the future of the child and of the nation, may not be interfered with except at a loss which will fall on the next generation. We admit a lively sympathy with the recommendation that street-trading by girls should be restricted, if not prohibited. This is a form of employment for which little can be said. Its unsettled character and precarious remuneration are unfavourable features, while it implies in the case of girls obvious dangers and temptations. It has only one advantage—that it is carried on in the open air. If permitted there can be no question that it should be regulated with much greater care than has hitherto been the case.

The Rebuilding of St. Bartholomew's Hospital.

THE City of London, the very medulla of the greatest empire which the world has ever seen, has but one hospital. It was founded nearly 800 years ago by a pious citizen with the help of the donations of the charitable. It served the sick, the poor, and the maimed, whose interests were looked after by the Augustinian canons of the Priory of St. Bartholomew up to the time of the spoliation by Henry VIII., and after that time by the care and skill of laymen who gave their time and knowledge ungrudgingly. Generations have come and gone, buildings have decayed and have been restored, fire and pestilence have swept over London, and still St. Bartholomew's Hospital stands where it did as a memorial to all men of Rahere and of the charity which it is the special boast of Christendom to feel for the poorer brethren. But with increasing knowledge, increasing population, and increasing facilities for intercommunication there has come, as an inevitable sequel to the march of 800 years, the absolute necessity for expansion and for repair.

For years past the medical staff of the hospital has been impressing upon the governors the crying need that exists for new buildings and for more land upon which to erect them; and the present is a fitting opportunity for us to recapitulate what we have said upon previous occasions as to the position in which matters stand, especially as some of the communications made to the lay press and to our own columns have not helped in making the issues clear. The area of the existing site now occupied by St. Bartholomew's Hospital is about four and a half acres. When it was known that Christ's Hospital was going to be moved from the City it was hoped that a great part, if not all, of the site of that institution might be secured for its neighbour, but owing to lack of means the authorities of St. Bartholomew's Hospital considered that it was only possible to purchase a small portion of land—an area of between one and one-third and one and one-half of an acre. The sum paid for this, the amount being fixed by arbitration by Lord Balfour of Burleigh, was £238,781. St. Bartholomew's Hospital is therefore now in possession of some six acres of land upon which to erect new buildings and to renovate existing ones, so as to put in hand reforms which are not merely desirable but absolutely necessary. For this purpose the Mansion House Committee has decided to appeal to the public for a sum of £350,000. This amount, it is calculated, will provide new buildings and other adaptations which will suffice for the needs of the hospital—i.e., for the needs of the poor and necessitous whom it serves—for some 20 years to come. But the great and serious question remains:—Will such a tentative and partial scheme be satisfactory? In our opinion there can be but one answer to this, and that answer is No. We feel that it would be a wiser policy for those in whose hands lies the government of St. Bartholomew's Hospital to take a bold step forward, to acquiesce in the recommendation of the medical staff, and to make it their endeavour to purchase at least two more acres of land. Sir Trevor Lawrence, the treasurer of St. Bartholomew's Hospital, in response to much acrid and some ill-informed criticism, has replied in a letter, which appeared in the *Times* of Dec. 1st that the governors would be only too willing to purchase more land were it not financially impracticable. His view is that the governors "would be wholly without justification were they to ask the public to give them an additional £320,000 to buy a further two acres of Christ's Hospital site. Such a purchase would bring the cost of land and new buildings together to at least a million." We are certain, with the treasurer of St. Bartholomew's Hospital, that the governors would be willing to buy more land, for they must be quite as much impressed with the necessity of acquiring more land as we are ourselves. But where we join issue with him is in his assumption that such purchase is impracticable. The scheme of renovation as at present set out is a temporary one. It may provide for the present situation, it may even suffice for a quarter of a century; but then, in less than a generation, the trouble will recur. Although two generous donors—namely, Her Majesty the Queen and the Worshipful Company of Mercers—have already given £1000 respectively towards the building fund, while the Goldsmiths' Company has subscribed £2000, the great mass of the population, both rich and poor, have not yet been approached. Unless one or two millionaires seize this very favourable opportunity of linking their names with those of Rahere and Guy the money will be obtained from the ordinary hard-working citizen, and he is a very shrewd and practical person. Such a man will not give even £1 towards a scheme which can be justly described as imperfect and without finality. Let the governors and the Mansion House Committee be bold and appeal with confidence for £800 000 or even for £1,000,000. If the Wesleyan community could raise a like sum for the purchase of the site of the Westminster Aquarium and for erecting buildings on the same and elsewhere, surely the citizens of London, the people of the British Isles, to say nothing of those beyond the seas, could be at least asked to do the same. Patients come to St. Bartholomew's Hospital from all parts of this empire. The hospital has sent out its sons to battle with disease and death in every quarter of the globe. Surely before folding the hands and saying "it is impossible" an attempt might be made. If it should fail the hospital will be in no worse plight than it is at present and the governors would not be oppressed with the uneasy feeling that they might have succeeded had they made the attempt.

The Lord Mayor has promised to call a meeting of the citizens of London at the Mansion House on Jan. 26th, 1904, when the governors will lay before them the plans of the proposed renovations and the sum of money required. We can only reiterate our hope that the governors will propound a large scheme, as final in its effects as anything can be in this world, and one which will set upon a sure ground the ancient foundation of St. Bartholomew's Hospital. The hospital has played a noble part in solacing the sick and weary through many hundreds of years and for the furtherance of that merciful work is in sore need of money. The sum required is large; there are other charitable institutions which are in equal need of help; and St. Bartholomew's is a well-endowed charity. We know all this but we also know that a grave expenditure of money is necessary and that half measures will in the end prove an extravagance. We are sanguine that if it be only made plain that the renovation to be carried out will be thorough and lasting the money will be forthcoming from the largest and richest city in the world.

Annotations.

"Ne quid nimis."

THE FINAL REPORT OF THE ROYAL COMMISSION ON ARSENICAL POISONING.

The final report of the Royal Commission on Arsenical Poisoning now on the eve of publication contains many points of interest with which we shall deal in a subsequent issue. The report is a valuable, we may almost say exhaustive, document, so large an amount of ground does it cover. The first part comprises a discussion of the medical and public health aspects of the question of poisoning by small doses of arsenic introduced by way of food or drink, an examination of further facts regarding the epidemic of poisoning due to beer in 1900, and an account of the similar outbreak in Halifax in 1902. Another section is devoted to the question of tests for arsenic in food and in substances used in food preparations, while other sections deal in detail with the various ways in which articles of food and drink may be contaminated by arsenic in the absence of sufficient precautions. Information is also given with regard to the degrees of purity which are obtainable commercially. The commissioners conclude with a review of the unsatisfactory condition of the present law and its administration in respect of food and drugs and make a series of important recommendations to secure improvement. In this brief *résumé* we have said enough to show not only that the report is a thoroughly interesting and valuable one but that the medical profession will expect legislation upon the lines of the recommendations of the commissioners.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

It may be within the knowledge of our readers that two years ago King Edward's Hospital Fund felt constrained to refuse a grant to that excellent charity the Royal Westminster Ophthalmic Hospital because of the unfortunate environment in which its splendid scientific work was being done. The building was terribly out of date and out of repair. Those responsible for the hospital were perfectly aware of its plight and bravely set to work to face the situation. They constructed an entirely new out-patient department on modern lines, enlarged and improved the wards, and generally perfected their building for its great objects. The visitors in connexion with King Edward's Hospital Fund, having seen the improvements, made a *satisfactory report upon the hospital*, the result being the grant from the Fund of a substantial sum; but the work of repair has cost the hospital much money and the charity, it must be remembered, is a poor one, for only poverty had prevented the management from making the improvements before. We understand that a sum of £2500 is due to the bankers. The comparatively modest wants of the Royal Westminster Ophthalmic Hospital ought not to go without response; an admirable charity, with which some of the chief ophthalmic surgeons of the country have been connected, and which is doing, and for many years has done, most valuable work among the poor ought not to seek assistance from the public in vain.

RADIUM AND TRANSMUTATION.

Radium still occupies the premier position as regards research and attention by scientific men And no wonder need be expressed that such is the case considering that as its properties are studied fresh revelations of a most remarkable kind are made. These revelations will be received with joy by those who cherish the view that the elements, in spite of their diversities of character, are after all but transmutations of one stuff. The hypothesis is attractive and several important and modern lines of research have been directed towards raising it to the dignity of theory if not to ascertained fact. In this connexion Sir William Crookes's investigations on radiant matter rank first. By his brilliant researches he was at length able to say, "we have actually touched the borderland where matter and force seem to merge in one another." Then came the recognition of radiant matter as electrons. In the meantime that wonderful property of certain elements—radio-activity—was being very carefully investigated, until at last perseverance and skill were rewarded in the discovery of that mysterious element now known as radium. The discovery of the x rays was a great stimulus to this path of research. Apparently remote, however, from the study of radiant phenomena was the discovery of argon in the atmosphere which in its turn led to the discovery of helium. As a matter of fact the most remarkable property of radium would probably have escaped observation had not helium been discovered and its properties made known. The energy manifested by radium is not due to radium at all but to the radio-active emanation which it produces from itself and these emanations would appear to be inert gases, perhaps argon or members of the argon group. The fact that helium was found in minerals containing uranium suggested that helium might be connected in some way with radio-activity. Eventually Sir William Ramsay and Mr. Frederic Soddy showed that though the fresh emanations from radium did not exhibit the spectrum of helium, yet as the radio-activity dies down helium is produced in small but in ever-increasing quantities. Helium would thus appear to have been born so to speak out of the emanations. Are these emanations related closely to the primordial matter, out of which all the elements known to chemistry by process of ages have been elaborated? We are thus brought face to face with the old theory of transmutation and a fresh light is thrown upon the genesis of the elements. Nature would seem to abhor elements of high atomic weights and her tendency is to resolve them gradually into elements of lower atomic weights. Just in the same way complex molecules in the organic world tend to break up into simpler substances. The great life processes elaborate complex materials, but as soon as these processes cease there is a resolution into simpler products accompanied by a loss of energy. Is it a kindred process in the inorganic world and are the elements of high atomic weight slowly disintegrating in favour of elements of lower atomic weight? If so, the dream of the alchemist may after all be realised. Gold is possibly being slowly resolved into copper or metals of a lower atomic weight than itself by a process of natural decay but transformation of copper into gold is by natural agencies improbable. According to this view some explanation may be found of the existence in nature of the metals known as noble in limited quantities; unless a method is forthcoming, however, by which the reverse process becomes possible gold may for ever remain a standard of currency as its dissolution would be so slow. The native amount may diminish but not sensibly in a very great period of time. If by artificial means, however, what appears to be the natural tendency can be overcome and reversed copper or tin or lead may be resolved into gold. Theoretically, such an accomplishment may come to be no more wonderful than is the building up of sugar or alcohol from its elements at the present time. Apart from speculating it is a wonderful thing that radium has shown that there exist in nature minerals containing elements of high atomic weight which have a tendency to crumble, so to speak, into elements of a lower atomic value, in consequence of which possibly the distribution of elements of relatively low atomic value, such as hydrogen, sodium, silicon, and oxygen, is common. This view leads us, naturally, to wonder whether the noble elements exist at all in burnt-out worlds.

DISTRICT COUNCILS AND SANATORIUMS FOR CONSUMPTION.

A Local Government Board inquiry of considerable significance and importance as regards the future development of the sanatorium movement was held last week at Swindon. The occasion for the inquiry was an application on the part of the Cirencester and Highworth rural district councils for sanction to borrow £250 each in order to make a capital contribution to the funds of the Winsley Sanatorium which is at the present time in course of erection at Winsley, near Bath, for cases of pulmonary tuberculosis occurring in persons other than paupers who are resident in one of the three counties of Gloucestershire, Somersetshire, or Wiltshire, or in the city of Bristol. Special interest attaches to the inquiry in that it is the first of its kind which has ever been held and if the Local Government Board sees fit to sanction the loans in question a precedent will have been created which is likely to be somewhat widely followed. In each case the capital sum referred to will secure to the contributing authority a right to nominate a suitable patient to the sanatorium subject to an annual payment by the contributing authority of £65. Such contribution will also enable each of the rural district councils to nominate a trustee for the land and building and to appoint a member of the committee of management. Some discussion took place at the inquiry as to the period over which the repayment of the loan should be spread and it appears that both district councils were prepared to accept the suggestion of the Local Government Board that as the arrangement between the sanatorium authorities and the district councils could be terminated by the district councils at any time after the expiration of five years the borrowed money should be repaid within that period. Probably there would have been no objection to sanctioning a loan for a longer period than five years had the arrangement between the district councils and the sanatorium trustees been permanently binding. The capital sum proposed in this case is certainly moderate for a permanent stone structure such as is here in question and the annual payment of £65 is also eminently reasonable. Of course, if what is known as a "temporary" or wooden structure were being erected in this instance a charge of £250 would be excessive and it remains for the future to determine whether the elaborate stone building so common in Germany or the chalet system which is to be found in vogue in certain sanatoriums in this country is the more satisfactory or economical method of dealing in part with the problem of pulmonary tuberculosis. The Winsley Sanatorium is intended for the accommodation of 60 patients and already a considerable number of the beds have, it appears, been taken up by local authorities such as the Bristol, Bath, Gloucester, and Swindon town councils. In these cases, however, the capital contributions are presumably being paid out of the current rates and no application to borrow money has been made. The application here referred to was, we see in the local press, supported by, among other medical men, Dr. F. T. Bond, medical officer of health of the combined Gloucestershire districts; Dr. Lionel A. Weatherly, chairman of the executive committee of the sanatorium; and Mr. J. Tubb-Thomas, county medical officer of health of Wiltshire. Obviously the decision of the Local Government Board will be awaited with great interest and it seems to us that we have in these proposals a means whereby a small local authority with but little money to spare may make an important experiment with a minimum of expenditure and that in the future such experiments can either be terminated or indefinitely extended. So many exaggerated statements have been spread abroad as to the actual value of sanatorium treatment by those who do not grasp sufficiently the problem involved that it would be deplorable were small local authorities at once to embark upon elaborate and expensive schemes under the belief that they would by this means stamp out tuberculosis in their districts. In the past there has been much overstatement in other directions and unfortunately some of the chickens are now coming home to roost. It is for this reason that we are able cordially to support the scheme put forward by the Cirencester and Highworth rural district councils.

THE CASE OF DR. LACHLAN GRANT.

Another step in the dispute between the Ballachulish quarriers and the directors of the quarry company has been taken. On Nov. 16th a deputation of the quarriers had a meeting with three of the directors and with the secretary of the company. The directors submitted proposals to the men regarding the question of Dr. Lachlan Grant by which it was agreed that the men should be empowered to appoint their own medical man and that if they appointed Dr Grant the company would withdraw its interdict against him. To this the men agreed and as the labour questions had also been satisfactorily settled it appeared that the end of the long fight was close at hand. On Nov. 19th, however, the men's agents received word that the directors had met on the day previous and had withdrawn this offer. The men thereupon very pluckily refused all the terms offered, saying that they would stand by Dr. Grant, so that matters are still *in statu quo*. Of course, however, a great advantage has been gained by the men in that three at least of the directors have agreed to settle the medical question as the men wish and it is to be presumed that Colonel Malcolm, who seems to be the head and front of the pigheaded attitude taken up by the company, will before long find that he is not acting in the best interests of the shareholders, many of whom, it is stated, are beginning to feel disgusted at the manner in which their directors have acted. No praise can be too high for the honourable and faithful way in which the men have acted towards their medical man. We pointed out in our issue of Oct. 24th, p. 1180, that the company had conceded one point and we are certain that if the men hold out, and it seems certain that they will do so, the shareholders will insist on the matter being settled in the men's way with or without the coöperation of Colonel Malcolm.

THE CENTRAL MIDWIVES BOARD.

AT the last meeting of the Central Midwives Board letters were read from the clerk of the Worcestershire county council and the medical officer of health of the county borough of Croydon, inquiring whether illiterate women unable to sign their own names were eligible for enrolment under the Midwives Act. The secretary was instructed to reply that the Board had no option to refuse applications from illiterate women. A claim for enrolment on the ground of having been in *bonâ-fide* practice as midwife for the statutory period within the Commonwealth of Australia was also allowed, the Board deciding that there was nothing in the Act to limit the area of midwives' practice to the United Kingdom. The Board, on consideration of applications for certificates, passed the names of 213 women for entry on the official roll, 143 being admitted as having been in *bonâ-fide* practice as midwives for one year prior to July 31st, 1902. From the proceedings at the last meeting of the Midwives Board it looks to us as if the new and official midwives will include for some little time some of those persons whose undoubted failings supplied the arguments for legislation.

SUBPERITONEAL RUPTURE OF THE BLADDER WITH ANOMALOUS SYMPTOMS.

THE following case, published in the *Scottish Medical and Surgical Journal* for November by Dr. W. Stewart, is of interest on account of the great difficulty of diagnosis. A man, aged 40 years, who had been drinking heavily, was while walking seized with pain in the lower abdomen so severe that he fell. The pain continued and vomiting came on. On the fifth day he was admitted to hospital suffering from pain in the lower abdomen, most intense over McBurney's point. He had not retained food since the onset and the bowels had not acted but flatus was passed. He said that he had no difficulty in micturition. The pulse was 78 and the temperature was 96·8° F. There was a purpuric rash over the body. The lower abdomen was tender and distended. The distension evidently was due to a large swelling, resembling a six months gravid uterus displaced to the right, which extended from the pubes to the umbilicus and from the right iliac fossa to the left beyond the middle line. It was firm, dull, very tender, and distinctly margined. Rectal examination showed that it did not extend into the pelvis. He passed much urine without difficulty. A No. 10 rubber catheter was easily passed and about nine ounces of clear urine containing a few dark-brown granules were drawn off. The urine did not contain albumin or blood. An enema gave a good result. On the sixth day the pain was less, he still vomited, and there was occasional hiccough. Laparotomy was performed by an incision midway between the umbilicus and the anterior superior spine of the ilium and parallel to Poupart's ligament. On opening the peritoneum from two to three quarts of clear, yellow, inodorous fluid gushed out. There was no smell of urine. The incision exposed the edge of a dark, smooth swelling, about an inch in thickness, extending upwards to the umbilicus. A coil of congested small intestine was adherent to it by means of recent lymph. On incision the swelling showed only blood-stained tissue and extraperitoneal fat. No tear in the bladder could be discovered. The abdomen was washed out, drained, and closed. The patient recovered from the operation but became gradually weaker and died on the ninth day. The necropsy showed recent adhesions between the intestines and anterior abdominal wall. There was no fluid in the peritoneal cavity. In front of the peritoneum and behind the pubes to the right was an infiltration of the tissues with greenish-brown non-fœtid fluid. On incising the bladder an aperture of the size of a pea was found communicating with the retropubic infiltration. In this case ruptured bladder seemed to be excluded by the normal micturition and the withdrawal of a fair amount of urine by the catheter. The swelling was undoubtedly due to extravasated urine. Dr. Stewart thinks that it percolated by osmosis into the peritoneal cavity, which accounted for its loss of odour. He regards the case as a warning against delay, for if the swelling had been incised on admission the urine would have been drained off and would not have passed into the peritoneal cavity.

THE TREATMENT OF SURGICAL TUBERCULOSIS IN CHILDREN.

THE following resolutions have been passed by the Society for the Study of Disease in Children :—

1. The Society for the Study of Disease in Children desires to express the opinion that the conditions under which children suffering from surgical tuberculosis—that is to say, tuberculosis of bones, joints, glands, and skin—are treated at the present time are unsatisfactory in result and unscientific in plan.

2. The Society is convinced that the treatment of such cases in urban hospitals cannot be justified by the results, but is attended by much *unnecessary suffering* and by *many preventable deaths*. The present haphazard methods are not economical but lead to a wasteful expenditure of time and energy and of hospital funds.

3. The Society is of opinion that children suffering *from surgical tuberculosis* should not be treated in hospitals situated in cities or large towns, but in properly equipped institutions in the country or at the seaside, such hospitals to be devoted to the treatment *of such cases* only, in the same way as open-air sanatoria are devoted to the treatment of pulmonary tuberculosis.

4. The general principles upon which such a hospital should be conducted are as follows :—

   (*a*) *No child shall be considered too young* for admission into such a hospital and provision should therefore be made for the reception and care of infants.
   (*b*) A patient should *only* be *admitted* into such a hospital with the intention of treating the case to a termination—that is to say, that a patient should not be discharged from the institution *until, in the opinion of the surgeon*, the child has recovered or is proved to be incurable.
   (c) Special institutions should be provided for the segregation and care *of* cases pronounced *to be incurable.*

The Society for the Study of Disease in Children will find the members of the medical profession in agreement with its view. Who is going to pay for the erection and maintenance of these hospitals remains a question for discussion.

ANKYLOSTOMIASIS IN WESTPHALIA.

AN interesting report by Dr. J. S. Haldane upon ankylostomiasis in the Westphalian collieries has just been issued.[1] Ankylostomiasis is primarily a disease of tropical and subtropical countries but an outbreak at the Dalcoath mine, Cornwall, has recently been described by Dr. Haldane and Dr. A. E. Boycott,[2] and in Westphalia the disease has assumed considerable proportions during the last few years. Except for an isolated case reported in 1886 the first cases in this district were observed in 1892 and up to 1895 23 cases had been recorded. Last year, however, up to October no less than 1355 cases distributed among 69 collieries were met with. The German Government is now taking active steps to stamp out the disease. In every colliery at least 20 per cent. of the men employed underground are selected by a properly qualified medical inspector and their dejecta are examined by him on at least three occasions. Any man found to be infected is treated and is not allowed to resume work until he is free from the parasite If the mine should prove to be badly infected the whole of the men employed underground are examined and if necessary treated, every man who has been treated being re examined monthly for three months No new hands are allowed to be engaged unless first proved to be free from the disease In addition sanitary receptacles for the use of the men under ground have to be provided and are emptied and disinfected daily The sick men are treated in hospital and if they have dependents receive sick pay Rooms are provided at the colliery for the use of the inspector and three specimens from each sample of dejecta are examined microscopically The treatment usually adopted is as follows —The patient receives in the evening five grains of calomel and in the morning on an empty stomach from two to three drachms of extract of male fern, followed by another five grains of calomel in the afternoon On the third day a dose of calomel is given in the evening if required On the fourth day the dose of male fern is repeated in the morning and the calomel in the evening The fæces are then examined for ova on the next six days and if ova are not found the patient is discharged If ova be present the whole course of treatment is repeated Male fern seems to be preferred to thymol

EPSOM COLLEGE

THE governors of the Royal Medical Benevolent College unanimously decided at a large and representative general meeting held on Nov 26th, under the presidency of the Earl of Rosebery to change the name of the institution to "Epsom College' and to add the following sub-title to all documents issued from the office of the charitable side of the work in London "Established in 1855 as a Public School with a Royal Medical Foundation" It is a happy coincidence that the council should have selected the fiftieth anniversary of the laying of the foundation stone of the college at Epsom for proposing an alteration in the title which has for a long time appeared desirable to many governors intimately connected with the institution, and even those conservative supporters who have been disinclined to favour a change must grant that the council has given very careful thought to the matter before coming to a decision We have no hesitation in saying that to medical men "Epsom College" will always appeal as an institution quite as worthy of generous support as when it bore the now discarded title with the "superabundance of adjectives' as Lord Rosebery humorously described it a few years ago, and to the charitable public the objects of the benevolent side of the work will be perfectly clear in the sub title "Royal Medical Foundation" The new brief title is now linked with the foundation of the college by Mr Propert close upon 50 years ago, and prominence is given to the fact which has been stated in these columns time after time that the college is a public school able to hold its own amongst the great schools of the country, whether looked at from the point of view of educational results, of scientific equipment, or of successes in the playing fields It may be added that friends of the institution have hoped for years that in due course an adequate foundation will be established in order to make secure for all time the 50 pensionerships and the 50 foundation scholarships which have been maintained for many years, instead of leaving them dependent upon the precarious income derived from donations and annual subscriptions But the realisation of this hope rests almost entirely in the hands of members of the medical profession for whose benefit the institution was founded, and when making testamentary dispositions those of them who are well endowed with this world's goods should remember that their less fortunate brethren have a strong claim on their charity through the medium of this institution That the teaching and scientific equipment of the college are good is undoubted and we have frequently drawn attention of late to the educational successes As to the athletic work of the school, both the Prince of Wales, who recently paid a visit to the college, and the President, Lord Rosebery, who, as a neighbour, is often in the playing fields, have referred in warm terms to this important feature The college has certainly all that can be reasonably expected for the welfare of its scholars with its extensive playing fields, an excellent swimming bath which has recently been reconstructed at a cost of about £1000 a detached sanatorium, a well equipped laboratory enlarged only a year ago, a lecture theatre, a lower school capable of accommodating 100 junior boys, fives courts, a biological laboratory, a modern laundry, a carpenter's shop, and a system of drainage which has been carefully arranged under expert advice in recent years at great expense The fee charged for sons of those not members of the profession, 75 guineas, is a moderate one, sons of medical men obtain a reduction of 10 guineas, there are entrance scholarships of £30 a year, and there are "council exhibitions' for the sons of less fortunate members of the profession, which reduce the fee to 35 guineas We have already referred to the foundation scholarships for the necessitous sons of medical men, the holders of which are educated, clothed, and maintained free of cost Owing to the generosity of the hospital authorities there are numerous scholarships at the hospital schools in London ranging in value from 120 guineas to £150 and through the liberality of living and deceased friends of the college there are also a number of scholarships and exhibitions for science and classics from £30 to £60 in value for boys leaving to go to the universities With the foregoing advantages, with a college standing on high ground in its own estate of about 80 acres in a district renowned for the purity of its air, and with the removal of the "meaningless but distasteful word 'benevolent,'" as Lord Rosebery described it at the meeting, may we not safely echo the prophecy which his lordship uttered that the day of that meeting will mark a new era of prosperity in the history of Epsom College

KORSAKOFF'S DISEASE, OR PSYCHOSIS POLYNEURITICA, IN WOMEN

FIFTEEN years ago the late Professor Korsakoff of Moscow described an assemblage of symptoms met with most frequently among chronic alcoholic subjects which he termed "psychosis polyneuritica" The cardinal features of this affection, according to him, were peripheral neuritis, amnesia, and pseudo reminiscence (false memories of events which have not occurred in the patient's life) In the *Journal of Mental Science* for October Dr John Turner, assistant medical officer of Essex County Asylum, gives an account of 12 cases of psychosis polyneuritica occurring in women Recent observers who have studied the subject state that alcoholism is accountable for nearly three quarters of the cases of psychosis polyneuritica but that it also follows typhoid fever childbirth, pyæmia, and arsenical poisoning Oppenheim, however, states that he could find no cases with the characteristic psychic disturbances in other than alcoholic subjects The psychical disturbance present is a form of mental confusion of toxic origin Common features noted by many observers are the happy disposition and feeling of self satisfaction of the patient Soukhanoff and Boutenko,[1] analysing a total of 192 cases, personal and collected from literature, find that 112 were males and 80 were females. There was not much difference in the age of onset in either sex, the greater number of cases occurred in both sexes between the ages of 30 and 50 years All the cases in women and about 91 per cent. of the cases in men presented marked multiple neuritis. The 12 cases recorded by Dr. Turner all presented the cardinal features insisted on by Korsakoff and other writers—viz., amnesia, disturbances of the patient's notion as to his position in time and space (disorientation), false memories, and a tendency to invent fabulous explanations of real occurrences (confabulation). Probably in all the cases and certainly in ten, says Dr. Turner, peripheral neuritis was present. "Over-indulgence in alcohol was ascertained in ten and was highly probable in the other two." The speech was "thick" in two cases, "drowsy" in another, and normal in the rest. Jolly and Bonhoffer look upon Korsakoff's disease and delirium tremens as closely allied affections, for in addition to the mental confusion (delirium) there is often a condition of tremor and jactitation of the limbs and the patient seems to be suffering from visual hallucinations (of animals) and fright. Four of Dr. Turner's patients "partook largely at one period of their illness of symptoms of delirium tremens" with visual hallucinations. As regards prognosis two died after a month's and after four years' residence in the Essex County Asylum respectively, three of the cases remain unrecovered in the asylum, and seven out of the 12 cases were discharged but of these the memory remained seriously impaired in four, so that only three out of the 12 could be fairly regarded as recovered. Dr. Turner is inclined to agree with Jolly that the term "Korsakoff's disease" includes a definite group of morbid conditions fulfilling some of the conceptions of "a disease."

THE NATIONAL DENTAL HOSPITAL.

Mr. John Tweedy, President of the Royal College of Surgeons of England, presided at the annual dinner of the past and present students of the National Dental Hospital, which was held at the Trocadéro Restaurant, Piccadilly-circus, London, on Nov. 27th. Mr. Tweedy, in the course of proposing the toast of "The National Dental Hospital and College," said that dentistry in the present day had reached a high plane of excellence. In his opinion the spirit that animated the practitioners of dentistry was different from that which he had noticed in his youth. In those days, referring particularly to the country districts, the blacksmith was very often the only person who had any pretension to the practice of drawing teeth. The spirit in which the modern dentist worked was that of the man of science and the philosopher, for his endeavours were directed not only to the well-being of his patients but also to the common good of the whole of the community. Mr. Tweedy, continuing, said that it was recognised by all that the practitioners of dentistry were actuated by the highest and best of all motives and he rejoiced to observe how highly their skill and knowledge were appreciated. In regard to the history of dentistry Mr. Tweedy had something to say on the authority of Herodotus who wrote in the fifth century before Christ. Herodotus said that in ancient Egypt medicine was practised on a system of separation—that is to say, a physician treated one disease and no more. Amongst these specialists were those who treated diseases of the teeth. Recent researches in the rich archæology of Egypt were considered to have confirmed the statement of Herodotus in this matter as in others. It has been said that mummies had been found whose teeth had been stopped with gold. That had been a cherished belief of Mr. Tweedy for many years but when he came to that dinner he was informed by Mr. C. S. Tomes, who he was sorry to say had become imbued with the iconoclastic and critical spirit of the age, that after inquiring into the evidence in regard to the existence of teeth of mummies which had been stopped with gold he found it rested on no better testimony than that of a dealer in mummies who had a skull to sell with teeth treated in the manner described. Mr. Tweedy said that in spite of Mr. Tomes he was going to believe in Herodotus and whether teeth were stopped with gold in the days of Herodotus or not it was certain that from the fifth century before Christ to recent times there had been little progress in dentistry. Embryology, histology, and chemistry had all increased the power of the dentist when dealing with diseases of the teeth, not merely when disease had occurred, but also in the prevention of such affections. Among the other speakers were the Dean of the College, Mr. P. Sidney Spokes, Mr. Tomes, F.R.S., Mr. G. H. New, Mr. G. W. Geekie, Mr. K. W. Goadby, Mr. A. S. Underwood, and Mr. W. Rushton.

BRITISH MEDICAL ASSOCIATION: THE FORTHCOMING MEETING AT OXFORD.

CONSIDERABLE interest has already been awakened in the University of Oxford with regard to the approaching meeting of the British Medical Association which is to be held in Oxford in July, 1904. Preparations are actively progressing in all the sections and as regards the section of pathology special steps are being taken to insure the success of the meeting. It is hoped also to make the museum of this section of interest to all the sections and as it will be arranged in the dissecting room of the department of human anatomy in the University museum it will be easily accessible and will be in contiguity to the meeting places of the sections. The local committee has drawn up a letter, a copy of which will, it is hoped, shortly be in the hands of every member of the Association, but in case it should fail to reach anybody we are requested to give its main contents in our columns. The museum will be arranged under the following headings :—

1. Specimens and photographs illustrating the latest advances in Medicine, Surgery, and Pathology.
2. Instruments for X-ray Work and Skiagraphs.
3. Colour Photography as applied to Medical, Surgical, and Pathological Work.
4. Micro-photographs and instruments for Micro-photography.
5. Instruments for Clinical Diagnosis.
6. Surgical Anatomy.

Provision will also be made for specimens bearing on any of the discussions in the various sections.

The local committee desires the coöperation of members of the association and will be glad to hear if any member is desirous of contributing to the museum. The committee will be glad to hear if there is any subject not mentioned above in which members are specially interested. It is anxious to arrange demonstrations of apparatus and specimens during the meeting. Other information may be had from the secretary of the local committee, Dr. E. W. Ainley Walker, University College, Oxford.

THE METROPOLITAN ASYLUMS BOARD AND SANATORIUMS FOR CONSUMPTIVES.

IN THE LANCET of Nov. 21st we noticed in a leading article the question of the establishment of sanatoriums by the Metropolitan Asylums Board for the treatment of consumptive persons. The matter was again discussed at a meeting of the Board on Nov. 28th, being brought up in the form of a report from the General Purposes Committee with reference to the resolutions passed by the metropolitan branch of the Incorporated Society of Medical Officers of Health in favour of the establishment by the Board of sanatoriums for consumptives.[1] A communication was also read from the Local Government Board inclosing a copy of a letter on the same subject which that department had received from the Poplar board of guardians in which the Local Government Board sought for the observations of the managers of the Metropolitan Asylums Board. The committee stated that it had given careful consideration to the whole question and to the representations made in the several communications which had been addressed to it on the subject from time to time during the past two years and it had come to the conclusion that the question of the establishment of sanatoriums for consumptive patients was one which called for an authoritative expression of opinion on the part of the Local Government Board. It accordingly recommended:—

---

[1] THE LANCET, Nov. 21st, 1903, p. 1444.

> question of the pro-
> ve patients and the
> rd and the various
> of health in regard
> thereto, are of opinion that the matter is one of such vital and far-reaching importance to the community at large and one which, if adopted by the managers, would entail so considerable an extension of their duties and responsibilities and so large an increase in their expenditure as to call for some authoritative expression of opinion by the chief health authority of the country—viz., the Local Government Board—before the managers are asked to take any definite action in the matter or to make any further inquiries in regard thereto; and that the Local Government Board, the several boards of guardians, the borough councils, and the medical officers of health be so informed.

The report and recommendations of the committee were adopted by the Metropolitan Asylums Board which now awaits, as we think very properly, the lead of the Government department which has charge of the health of the country.

HERTER LECTURES.

FOR a number of years Dr. C. A. Herter has given a course of lectures on pathological chemistry in the University and Bellevue Hospital Medical College, New York. On retirement from his work there, on receiving the appointment of professor of pharmacology at the Columbia University, he was desirous of perpetuating the course in his old college. To this end he has endowed a lectureship which, we understand, is to be offered annually to others who have made their names in this department of science. Professor W. D. Halliburton, of King's College, London, has been selected to give the lectures in the coming year and he has chosen as his subject the Bio chemistry of Muscle and Nerve. The lectures will commence on Jan. 4th, 1904.

A TESTIMONIAL, consisting of an illuminated address and a silver plate embossed with the arms of the Swiss cantons, was presented to Professor Arthur Gamgee on Nov. 23rd as a token of gratification on the part of his many friends, including his British colleagues in Montreux, on the occasion of his recently receiving the degree of LL D. from the University of Edinburgh. In the few appropriate words with which Professor Gamgee expressed his gratification at so warm an expression of kindly feeling he took occasion to remark on the good feeling which prevailed generally among members of the British medical profession, in which respect they compared favourably with their foreign colleagues.

AT a recent meeting of the subscribers to the proposed testimonial to Dr. T. Henry Green on the occasion of his promotion to the position of consulting physician to Charing Cross Hospital it was decided that it should take the form of a prize in clinical medicine. The contributions have already reached a handsome sum and the list will presently be closed, but those of Dr. Green's old pupils and other friends who may not have had an opportunity of contributing may still do so by communicating with Dr. C. J. Woollett, Ambleside, Streatham, London, S.W., the honorary treasurer of the fund.

AT the usual annual meeting of the Royal Society held on Nov. 30th (St. Andrew's Day) Sir Archibald Geikie was chosen as successor to Sir Michael Foster as joint secretary of the society. An influentially signed letter supporting the apointment of Professor W. D. Halliburton was published but Sir Archibald Geikie, the official candidate, was successful by a large majority. Professor Halliburton and Professor Rose Bradford were elected members of the council of the society.

A DEMONSTRATION has been arranged on Saturday, Dec. 5th, at 11 A.M. at the South-Western Polytechnic, Manresa-road, Chelsea, to illustrate the various systems of physical exercises at present in use in schools. Lessons of a quarter of an hour's duration will be given in the German system, Ling's Swedish system, English military drill, musical drill, and the model course. All who are interested in physical education are invited to attend.

THE medical officer of health of Cape Colony states that for the week ending Nov. 7th no case of bubonic plague was discovered throughout the colony. Plague-infected rats were found at Port Elizabeth, Knysna, and at Queenstown. As regards the Mauritius a telegram from the Acting Governor, received at the Colonial Office on Nov. 27th, states that for the week ending Nov. 26th there were 77 cases of plague and 41 deaths from the disease.

Dr. Louis Sambon, lecturer at the London School of Tropical Medicine, will read a paper on Sleeping Sickness before the Epidemiological Society of London on Friday, Dec. 11th, at 11, Chandos-street, Cavendish-square, W., at 8.30 P.M. Dr. Sambon is now in Paris studying the cases of sleeping sickness which have recently been brought over from Uganda and it is hoped that a good discussion will follow the reading of the paper.

THE committee of the Macedonian Relief Fund has received an anonymous offer to subscribe the sum of £1000 conditionally upon the total amount subscribed direct to the fund by Jan. 1st, 1904, reaching £20,000. Recent cables published by the Macedonian Relief Fund describe terrible distress in the regions south of Monastir.

THE annual dinner of the Otological Society of the United Kingdom will be held at the Trocadéro Restaurant, Piccadilly, London, W., on Monday next, Dec. 7th, at 7.30 P.M. The chair will be taken by the President of the society, Dr. Urban Pritchard, and a good attendance is anticipated.

MEMBERS of the medical profession should know that copies of the recent digest of the criticisms on the British Pharmacopœia, 1898, may be obtained from the publishers of the General Medical Council, Messrs. Spottiswoode and Co., 54, Gracechurch-street, London, E C., price 1*s*., or post free 1*s*. 1*d*.

IT is proposed to form a Masonic Lodge in connexion with the University of Durham, which will hold its meetings in London, and those who are interested in the project are requested to communicate with Dr. Frederick Spicer, 17, Wimpole street, London, W., as soon as possible.

Sir Patrick Manson is announced to deliver an address at the London School of Tropical Medicine at 3 P.M. on Monday next, Dec. 7th. The address will form a *résumé* of the past and present work of the school, with indications of what it is hoped the school will do in the future.

THE annual dinner of the Royal Free Hospital and London School of Medicine for Women will be held at the Hotel Cecil, Strand, London, W.C., on Tuesday, Dec. 15th, at 7.15 P.M.

THE King has appointed Dr. George Turner, medical officer of health, to be a Member of the Legislative Council of the Colony of the Transvaal.

Sir Hermann Weber delivered an interesting lecture on Thursday last at the Royal College of Physicians of London on the Prolongation of Life.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THURSDAY, NOV. 26TH.

THE third meeting of the session took place to-day, when Sir WILLIAM TURNER, K.C.B., again presided.

Dental Business.

The Executive Committee presented the following report on the dental business transacted since the last session of the Council, viz :—

> (1) The prescribed conditions having been duly fulfilled in each case, the names of the undermentioned persons have been restored to the Dentists Register from which they had been erased in conformity with the provisions of Section 12 of the Dentists Act, 1878: John J. Atwood, Alfred T. Broadlick, Joe E. Brook, David Cormack, George G. Forster, Albert E. Mallan, Leonard Mathison, Albert Miles, Arthur H. Smith, Irwin B. Street, Henry W. Watson, Frederick Wells, Charles W. Whiteley.
>
> (2) The Committee received from the Foreign Office, through the Colonial Office, and entered on its minutes, information in regard to the position of qualified British dentists in the German Empire.
>
> (3) The Committee considered an application from an unregistered dentist for the reconsideration of his application for registration as a dentist under Section 37 of the Dentists Act, which raises a point of law in regard to certain apprentices, and resolved: "That the application with accompanying documents be referred to the General Council for its consideration."
>
> (4) An application from another unregistered dentist was also considered and it was resolved: "That the Executive Committee do not recommend the Council to accede to Mr. Spero's application."
>
> (5) The Committee received from the Privy Council Office copies of Royal decrees republishing sanitary laws in force in the Netherlands, which were entered on its minutes and which show, *inter alia*, the position of British dentists in the Netherlands.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the report was received and entered in the minutes.

The Council then dealt with the case referred to it by the Executive Committee—namely, the application from Mr. I. E. Bush of Melksham, Wilts, for the reconsideration of his application for registration as a dentist under Section 37 of the Dentists Act, 1878. This section deals with the case of dentists in practice prior to the passing of the Act and apprentices.

Mr. TOMES explained in detail the action of the Council in administering the section and the effect of the judgment of Mr. Justice Hawkins and Mr. Justice Wright in the Spero case. In the case of apprentices it was decided that the period of grace expired on August 1st, 1879, while the apprenticeship of Mr. Bush expired three weeks later than that date. The man to whom he was apprenticed did not register, but in a statutory declaration he described himself as a "pharmacist and dental practitioner" and said that he gave to Mr. Bush as efficient an education in dental practice as he then knew. Mr. Bush had practised as a chemist for all the period of the Dentists Act and so lately as 1889 he passed the minor examination of the Pharmaceutical Society and became registered as a chemist and druggist. In 1896 the Executive Committee recommended Mr. Bush for registration but the Council did not approve the recommendation.

The PRESIDENT: Have you any motion to move?

Mr. TOMES: I move that the application be not acceded to.

Dr. MACALISTER: I second it.

This motion was put from the chair and at once agreed to.

The Case of Mr. Allan Douglas Cameron.

The Council proceeded to the consideration of the case of Allan Douglas Cameron, registered as of Durban, Natal, with the triple qualification of Scotland, 1899, who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor:—

> That you abused your position as a medical man by committing adultery with a patient—namely, Mrs. Tothill, a married woman whom you had been attending professionally, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated July 28th, 1903, in the case of Tothill *v.* Tothill and Cameron, in which you were the co-respondent.

The complainant was Mr. Charles Tothill.

Mr. Cameron did not attend, the PRESIDENT saying that he had been informed that he was at present in India.

Mr. LEWIS E. FAWCUS, solicitor, appeared on behalf of the complainant. He read a statutory declaration made by his client, stating among other things that Mr. Cameron attended his wife in Durban and also in this country and expressing his opinion that the case was a flagrant one of breach of professional confidence. Mr. Fawcus handed in a transcript of the shorthand notes of the proceedings in the Divorce Court.

Mr. JOHN TOTHILL, a brother of the complainant, gave evidence to the effect that Mr. Cameron was introduced to the family as the medical attendant of Mrs. Tothill.

The Council deliberated in private for a time and thereafter the PRESIDENT announced that the Council had judged Mr. Cameron to have been guilty of infamous conduct in a professional respect and had directed the Registrar to erase his name from the Medical Register.

The Case of Mr. Robert Fawcitt Granger.

The Council next proceeded with the case of Robert Fawcitt Granger, registered as of 85, Church-street, Whitby, with the triple qualification of Scotland, 1889, who had been summoned to appear in consequence of his conviction at Plymouth, on Sept. 16th last, of the offence of unlawfully and wilfully neglecting his three children.

Mr. WINTERBOTHAM, the Council's solicitor, explained that the trial lasted two days and it was shown that the offence had resulted from intemperance on the part of the parents and both Mr. Granger and his wife were sent to prison for two months each, the children meanwhile to remain in the workhouse.

Mr. GRANGER, at the request of the President, read a letter sent by him on Nov. 17th to the Council's solicitor. In this he declared that the statements which had been made by witnesses at the trial had been animated by strong feelings of dislike against him and his wife. The case had been greatly exaggerated. He had no means with which to procure drink and if there was a little neglect of the children, one of whom was unmanageable, it arose from thoughtlessness, not wilfulness. He trusted that the Council would take a lenient view of the case as it would be a serious matter for his wife and family if it did not.

In answer to questions Mr. GRANGER said that the district in which he lived was a very poor one and the children would play in the streets. They might thus now and again get dirty, but he did his best to keep the boys clean and his wife and he robbed themselves to give them food. He had been in Plymouth since August a year ago, but there was very little to be earned. In five weeks he had only made 1s. He was trying to do his best until most of his furniture was taken away under distraint. It was true that silk dresses had been seen in a bedroom, but his wife had got these five years ago or more; she had got none during the last three or four years and her jewellery and his and some of his books had to be sold to get food and to keep a home together. He had not tasted spirits this year and only had a glass or two of beer a day. He had been in practice at Whitby, Yorkshire, before going to Plymouth. He had left Whitby because of family troubles.

Mr. GEORGE FREDERICK WATTS, an officer of the Royal Society for the Prevention of Cruelty to Children, gave evidence that the statements on which that society prosecuted the Grangers were true. The report was that they drank but he did not see them drink.

Dr. MCVAIL wished to know what was the cause of the great decline in the social status of the Grangers in three or four years and was there any reasonable ground for believing that that cause was not likely to arise again?

The PRESIDENT: If Mr. Granger were to tell us that he has become a total abstainer.

Mr. GRANGER: I admit a glass or two of beer a day but I have not tasted spirits this year. If I can do without spirits I can do without malt liquor. If the beer is to be a drawback I will give it up as well.

After the Council had deliberated in private

The PRESIDENT announced the decision. Addressing Mr. Granger he said: The Council has had to summon you in connexion with a conviction and I think you know perfectly well what it is that led to your being convicted—that your habits were such as had reduced you to this state of absolute impecuniosity that has been described to us in the evidence. The Council has very carefully considered your case and they are willing to give you an opportunity to redeem yourself. Now, in order to do that I should say, speaking to you as an individual, that there is only one course open to you and that is to cease to take alcoholic drink of all kinds. Well, the

Council has resolved to give you an opportunity of redeeming yourself and you will have to appear here when the Council meets in May next and will have to produce satisfactory evidence in the way of certificates from persons upon whose word we can rely that you have ceased the bad habits you have been indulging in, and the Council will be prepared to say whether they will allow you to have your name retained on the Medical Register. We give you six months' probation.

In answer to Mr. GRANGER

The PRESIDENT said that of course in the interval he could go on practising.

Mr. GRANGER: Thank you.

The Case of Mr. David Barnett Bradlaw.

This was a case of consideration of the facts proved against David Barnett Bradlaw registered as of 4, Harrington-street, Dublin, Lic., Lic. Midwif. 1899, R. Coll. Phys. Irel., Lic., Lic. Midwif. 1899, R. Coll. Surg. Irel. Mr. Bradlaw was summoned to appear before the Council in May last to answer a charge formulated by the Council's solicitor as follows:—

> That you, being a registered m[illegible] yourself in dental practice with [illegible] t the dental practice carried on at [illegible] oresaid is extensively advertised by pamphlets and in newspapers and otherwise.

At the close of the hearing of this charge the Council found it proved but adjourned further consideration for six months in order to give Mr. Bradlaw the opportunity of remodelling his business conduct to its satisfaction.

On the case being called to-day Mr. D Barnett Bradlaw appeared for himself and Mr. R. W. Turner, instructed by Messrs. Bowman and Curtis-Hayward, solicitors, for the British Dental Association.

Mr. BRADLAW, in answer to the President, said that he had written to the Council's solicitor. The letter stated that his brother (Mr. H. J. Bradlaw) had ceased to practise at the address in Inverness-terrace and that he (Mr. D. B Bradlaw) had conducted his practice in accordance with the best traditions of the profession. He had nothing to add to that.

Mr. TURNER said that there was every reason to believe that since May last Mr. Bradlaw had conducted his practice in a proper manner and that the issue of the objectionable advertisements in connexion with the Inverness-terrace address had ceased.

The PRESIDENT, after the Council had deliberated in private, addressing Mr. Bradlaw said: The Council having given a further consideration to the facts proved against you do not judge you guilty of infamous conduct in a professional respect.

Mr BRADLAW: Thank you.

The Case of Mr. Louis Edward Delmege

The next case dealt with was that of Louis Edward Delmege, registered as of Fern Bank, Burton, Westmoreland, Lic. R. Coll. Surg. Irel. 1877, Lic. R Coll. Phys. Edin 1879, who had been summoned to appear before the Council in consequence of his conviction before an interim sheriff-substitute of Lanarkshire at Glasgow on Sept. 30th last of the offence of desertion of his wife and child, for which he was sentenced to imprisonment for 40 days.

Mr. Delmege appeared with his solicitor, Mr F. J. Shaw.

Mr. SHAW explained that Mr. Delmege had married a Creole lady in Jamaica but the marital life had turned out unsuccessful and he had not only had to give up his practice in the island in question but had lost upwards of £2000. After a visit to the West Coast of Africa he came to England but in March last the state of things came to be such that a separation was agreed to, Mr Delmege consenting to allow his wife £10 a month. She left their house but he had to go abroad. On his arrival at Madeira he communicated with his wife but finding that there was not much prospect of work at Madeira he returned to England. Meanwhile, [illegible] of the deed of separation were [illegible] it to Glasgow, where she had [illegible] and child on the parish." Mr. Delmege was arrested in London on Sept. 19th. At his trial he was unassisted. He had been advised to be represented by a legal practitioner, but he thought that with the correspondence in connexion with the separation the case was a safe one for him. He (Mr. Shaw) was told there was good reason to think that the conviction was faulty and that it could be quashed but that could be brought about only at an expense of about £250 which Mr. Delmege was reluctant to incur.

Mr. P. CARROLL, *clerk to Mr. Shaw, gave evidence* showing that Mrs. Delmege had agreed to everything proposed and all was done except the revision of the deed. She had consented to the withdrawal of all accusations made by her against her husband. Mr. Delmege had no knowledge of the warrant and he was arrested in Guildford-street, London, by two Scotch detectives and taken to Scotland by them. Witness could not tell how it was the warrant could be operative out of Scotland but it was used in London and the police paid the expense of conveying Mr. Delmege to Glasgow.

Sir JOHN BATTY TUKE said that it was the most extraordinary thing he had heard of if the Scotch police took the trouble and expense of sending two detectives from Glasgow to London without having the warrant backed by an English magistrate.

The PRESIDENT: I do not think that a warrant issued in London would have run in Glasgow.

After a brief deliberation of the Council in private,

The PRESIDENT said: Mr. Delmege, after hearing your case the Council has decided not to erase your name from the Medical Register.

The Council concluded the day's sitting *in camerâ.*

FRIDAY, NOV. 27TH.

The Council met again to-day, Sir WILLIAM TURNER presiding.

Primary Examinations: Special Committee Appointed.

Mr. BRYANT, chairman of the Examination Committee, presented to the Council three reports on the inspection of the primary examinations—one with reference to the Scottish Conjoint Board, another with reference to the Irish Conjoint Board, and the third "on the whole series of inspections of primary examinations." Each of the reports was formally received and ordered to be entered in the minutes.

R[illegible] ON THE REPORT BY THE [illegible] CHEMISTRY, PHYSICS, [illegible] BOARD IN SCOTLAND [illegible] AND SURGEONS OF [illegible] PHYSICIANS AND [illegible] TRIPLE BOARD [illegible] 4TH, 1903

[illegible] which was [illegible] al arrange- [illegible] and an oral [illegible] wers of the [illegible] presented [illegible] three classes.

Two examiners attended for each subject and the papers were divided between them. If the examiner who read any paper considered it to be worth 40 per cent or more, the other examiner did not read it But if a lower percentage was awarded by the reader of the paper then his brother examiner had also to read it and a joint mark was agreed upon. [illegible] 15 minutes at least was allowed to each [illegible]

The paper in elementary biology consisted of four questions and [illegible] of these had to be answered. The questions were well [illegible] ors, to ascertain the knowledge of [illegible] candidates. The marking was [illegible] the other written parts of the [illegible] opinion of the visitors, was not a [illegible] the paper is the least important [illegible] ion that the standard can well be [illegible] rt, and the easiest part, of the [illegible] s no more than 20 per cent in this part he must make 60 per cent. at the least in the oral in order to [illegible] ground which he has lost

The examination in physics is distinct from the examination in chemistry; it is conducted by different examiners with a separate paper. The value accorded to it is equal to the value assigned to the chemistry examination. The synopsis is ample and the details are well selected.

In the paper were four questions; three only were to be answered, of which the question on magnetism was one. The paper was considered by the visitors to be an easy one.

The oral examination lasted 15 minutes for each candidate and a variety of apparatus was on the table for use, out of which each candidate was shown a selection of three or four pieces. In each case he was asked what it was and how it acted. He was required to fit one part to another and to explain its working and to show how it was used and for what purposes it was practically employed and generally to explain the principles which underlie its action.

"The cross-examination brought out very clearly whether the candidate had an effective knowledge or whether he had merely a m[illegible] of book work."

[illegible] being too severe.

[illegible] sisted of a paper and an oral examination which lasted from 15 to 20 minutes, with a short practical examination occupying from five to ten minutes.

[illegible] red by the visitors to be sufficient for [illegible] mistry and to have been well drafted; but [illegible] of "the practical portion," which "consists of a single sentence, "does not indicate to the student the necessity of becoming acquainted with the way to perform any chemical operations or experimental work. This portion of the syllabus is totally inadequate."

The chemistry paper consisted of four questions, of which three were to be answered; the questions were considered by the visitors to be easy. The marking was fair in the higher numbers and very lenient in the lower numbers

The oral examination was searching and an abundant supply and variety of chemical substances were placed on the table. Each candidate was shown three or four specimens in succession and he was asked to say on their inspection what each was, what its formula was, how it was prepared, and what were its properties. Indeed, a kind of cross-examination was made and so conducted as to show whether the candidate had an effective and intelligent knowledge of the subject. This part of the examination is said by the visitors to have been admirably conducted.

The practical examination, which lasted about six or seven minutes, followed, "and, since the function of examinations is to secure efficient teaching and to ascertain whether the candidate has profited by the teaching," the visitors' decided opinion is "that the practical examination fails to perform this function and that the candidates were in many cases neither trained to understand experimental methods and chemical manipulations, nor to perform any chemical work which would be useful to them in after life or as an introduction to the study of physiological chemistry."

The visitors give a complete account of the examination of a single student to make the method of examination clear. It is interesting reading.

The committee of management of the Scotch triple qualification, in their reply to the visitors' report, recognise gladly the favourable opinion given upon the conduct of the examination by the visitors and that the examination was carried out to their satisfaction except in the department of practical chemistry. As regards that department the committee of management admit that it is not what they would desire. They recognise the fairness of the remarks made by the visitors and will give what effect they can to them.

The conclusions arrived at by the visitors are set forth in the following:—

"SUMMARY.

"1. The examination in systematic chemistry, like that in physics and biology, was carried out in an efficient, fair, and painstaking manner.

2. The oral examination, to which all candidates were subjected, was admirably carried out and is a most valuable feature of the examination.

3. The standard of the theoretical examination is a low one, but the percentage of marks in the oral examination is high for a pass and is a very satisfactory test of the candidates' knowledge.

4. The practical examination in chemistry is hardly worth the name, and even if it amounted to much more than it does it is of a kind that is of extremely little value, either as a training for the student's intellectual powers, or as a preliminary to the study of physiology, or as giving him something that will be useful to him in his future career."

These conclusions this Examination Committee now endorse and the committee regard the examination in practical chemistry as insufficient.

REPORT BY THE EXAMINATION COMMITTEE ON THE REPORT BY THE VISITORS OF THE EXAMINATIONS IN CHEMISTRY, PHYSICS, AND BIOLOGY OF THE CONJOINT EXAMINING BOARD IN IRELAND.

"Candidates are admitted to this examination who have studied at any recognised school of medicine and also if they have pursued their studies at any of the schools or other institutions recognised by the English Conjoint Board, whether such schools or other institutions have been approved by the General Medical Council or not."

The general arrangements for the conduct of the examination were by the visitors pronounced to have been excellent.

In each of the three subjects of biology, chemistry, and physics there was a paper, for the answering of which one hour and a half was allowed and an oral examination of 15 minutes; in chemistry there was also a practical examination.

A member of the committee of management attended each examination as a visitor, whose duty it was to report to the committee. Every candidate came under the notice of both examiners in each part of the examination.

"A 'cipher' agreed to by both examiners in any part—written, oral, or practical—of a subject involved rejection. Candidates who pass in all subjects at any examination and obtain 70 per cent. of the total marks are deemed to have passed with honours and receive a certificate to that effect on completing their final examination," a pass mark being 50 per cent.

At this examination nine out of the 76 candidates passed with honours.

"There was no meeting of examiners for the final adjustment of marks. Each pair of examiners having decided upon the marks to be given in their subject sent them to the secretary, who entered them on a list which was examined and signed by the visitor of the examination, before it was made public. It will be noticed," add our visitors, "that the absence of any examiners' meeting prevents the possibility of a candidate's marks being raised in one part of a division in order to enable him to pass and because he has done well in the other part."

The visitors endorse this plan of finally dealing with the marks.

ELEMENTARY BIOLOGY.

The syllabus was pronounced by our visitors to be a satisfactory one; they note that the physiological rather than the morphological aspect of biology was insisted upon. The visitors were "very much impressed with the amount of useful elementary knowledge of physiology possessed by quite a number of candidates."

The paper consisted of five questions, all of which were expected to be answered. Our visitors were satisfied with the questions and regarded the standard as satisfactory.

The oral examination was pronounced by our visitors to be of good character and in their opinion a very fair standard was exacted. There was a sufficient supply of specimens, many being fresh, to serve as pegs upon which physiological questions could be asked.

The examination as a whole was of a highly physiological character and to prove this the visitors append full notes of a single examination.

EXAMINATION IN PHYSICS.

This examination, like that at Edinburgh, is distinct from the examination in chemistry and is conducted by different examiners by means of a separate paper, and also an oral examination.

Our visitors pronounce the syllabus to be excellent and regard "a good detailed syllabus as necessary in this subject, because it is wide and complex, while only a comparatively small selection is needed by, and possible to, a medical student."

The paper consisted of five questions, all of which had to be attempted; it was an easy one and the knowledge displayed by the candidates who passed was satisfactory.

The oral examination lasted 15 minutes. A variety of apparatus was placed on the table and each candidate was examined upon a selection of these and asked to explain their construction and use. He was questioned about some of the mechanical and physical laws in such a way as to ascertain how far he understood the application of these laws to practical matters.

The questions given were practical and the marking was strict.

EXAMINATION IN CHEMISTRY.

This examination consisted of a paper of five questions, an oral examination of 15 minutes, and a practical examination for which three hours were allowed.

The syllabus is described as being of the usual description, although it failed to include certain elements which our visitors held that a medical man cannot afford to neglect.

Our visitors doubt whether a detailed syllabus is so good "as a simple statement that a candidate is required to be acquainted with the 'elements of chemistry, including typical examples of the principal classes of carbon compounds.' The detailed syllabus certainly facilitates cramming and encourages neglect of everything, however important, which does not happen to be named in it."

The paper of five questions, all of which had to be attempted and were well chosen, was an easy one. The knowledge of the candidates who obtained half marks was satisfactory but several of the weak papers were too highly marked.

The oral examination lasted 15 minutes. The questions were well selected but no specimens were provided to be identified on inspection by the candidate. Our visitors "think it would be an improvement if typical chemical substances were brought in and made use of as pegs on which to hang questions in this part of the examination."

THE PRACTICAL EXAMINATION.

This examination, our visitors report, was of the old-fashioned test-tubing kind, but it was well conducted and good

Our visitors hold, however, "that it is of very little service either in securing good training in practical chemistry or in ascertaining whether a medical student can perform experiments and draw conclusions from them."

During the three hours allowed three substances had to be examined and identified. Some of the candidates did their work well. The knowledge of others was empirical and therefore useless. "The examination compared very favourably with the absence of any substantial practical examination at the Edinburgh Board, but unfavourably with the examination at the London Conjoint Board."

Our visitors suggest "that teaching and examination alike would be improved without loss of time or hardship to anyone if for two-thirds of the examination there were substituted a mixture of two oxides or salts and the candidates were required to separate and identify the two metals or their oxides and prepare and show to the examiners a specimen of a characteristic compound of one of them."

The committee of management of t[illegible] venture to doubt "whether a knowledge of the [illegible] gnising the salts or other bodies used in [illegible] student than those of separating two metals or two oxides."

The following conclusions are given by way of summary to their report by our visitors upon the examinations in biology, physics, and chemistry.

SUMMARY AS TO BIOLOGY.

By way of summary to this part of the examination our visitors report that they "should much like to see a short practical test added to the examination in biology," to which the committee representing the body visited answer "that the absence of the practical examination at this stage of the student's course is more than compensated for by the practical examinations in dissecting and histology at the end of the second year."

SUMMARY AS TO PHYSICS AND CHEMISTRY.

1. The examination in physics was carried out in an efficient, fair, and painstaking manner and the arrangements were excellent.

2. The examination in theoretical chemistry was also carried out in an efficient, fair, and painstaking manner.

3. In both the oral examination was a valuable feature, while the written papers received full consideration in the ultimate decision.

4. The standard of the theoretical examination was a low one, but the marking was strict *except in the poorer papers*; and as a general rule the percentage of marks in the oral examination was high for a pass and was a satisfactory test of the candidate's knowledge.

the written papers all the questions had to be attempted and the examiner knew at a glance where the candidate's knowledge fell short.

5. The practical examination was very good of its kind, but it was a kind that is of little value, either as a training or as a preliminary to the study of physiology and it injuriously affects the kind of education which candidates receive.

6. The average work of the candidates [illegible]

REPORT BY THE EXAMINATION COMMITTEE ON THE WHOLE SERIES.

The final report of the visitors upon the conclusion of their visitation of the first medical examinations of the Conjoint Boards of England, Scotland, and Ireland, with the Apothecaries' Society of London, consists of a c [illegible] their personal c [illegible] three sciences [illegible] take; and it is [illegible] the members c [illegible] merits of the [illegible] taken place.

The visitors drew attention to the fact which should not be overlooked: "that the three sciences in question cover a vast field of knowledge and that the time which students can give to them is extremely limited." [At page 19 of their report they assure us that "they have made no attempt to indicate that one examination is better than another as a whole," and "that they have recognised in each some merit peculiar to itself and have pointed out in each some defect."]

BIOLOGICAL EXAMINATION.

[illegible] and [illegible] to [illegible] be [illegible] on [illegible] higher percentage in each subject than [illegible] ubject which may be [illegible] examinations there is [illegible] usively oral. At the [illegible] well as an oral test. [illegible] xaminations visited, [illegible] gy), a practical test [illegible] uation is to be real [illegible]

The practical test, which requires practice before proficiency is reached, is a guarantee against cram, for such "cannot teach a student how to stain and mount a microscopic specimen or to dissect out a given structure in a frog or rabbit."

The visitors regard the omission of a paper as a grave one, "since by virtue of the double requirement of paper and oral, it is possible to cover a larger amount of ground than can be covered where only an oral is resorted to."

The written test, the visitors point out, "requires a student to have [illegible] down his [illegible] another [illegible] ulum the [illegible] "If we were pressed for an opinion on this point we [illegible] overburdened as the student's curri [illegible] biology is the subject which could [illegible] much, perhaps all, that is valuable [illegible] atomical and physiological courses, [illegible] h on somewhat broad lines in a student's second year.

Should this plan not be followed, the system adopted by the Irish Board is one of which the visitors speak much in favour. According to the practice of that Board, if not according to its printed regulations, the examination is one mainly concerned with the principles of elementary physiology, the course of instruction being utilised as a *preparation in facts* and methods for the later course in physiology.

EXAMINATION IN PHYSICS.

[illegible] in physics and chemistry into [illegible] physics has a separate paper or [illegible] there is no separate paper in [illegible] the subject, one of which must be answered, are given in the conjoint paper on physics and chemistry.

The requirements of the Apothecaries Society are similar, with the addition of an oral examination in physics as part of the chemistry examination.

At the Scotch and Irish examinations there was a separate paper on physics by distinct examiners, and an oral examination, at which [illegible] subject."

The visitors condemn "the plan of permitting the principle of com- [illegible]

EXAMINATIONS IN CHEMISTRY.

The paragraphs on the subjects of the examinations in chemistry require careful reading, for the visitors report that "it has seemed [illegible] ordinary ele [illegible] carbon comp [illegible] "at none of [illegible] secure a slig [illegible] great and gr [illegible] the carbon compounds, this is a serious defect." They suggest, as [illegible] the different examinations [illegible] ch other, differing only in [illegible] he elements of chemistry is unnecessary.

On the other hand, a synopsis of the carbon compounds is unavoidable and the visitors kindly provide a new synopsis as follows:—

"SYNOPSIS INDICATING THE RANGE OF SUBJECTS OF EXAMINATION IN CHEMISTRY.

"The elements of chemistry, its principles and laws as illustrated [illegible] properties, and relations of examples of each of the principal classes. Cyanogen and its compounds; hydrocyanic acid; urea. Methane; ethane, ethylene, acetylene. *Chloroform. Iodoform* Methylic and ethylic alcohol; aldehyde, chloral, ether, acetone Formic and acetic acids; oxalic, lactic, tartaric, malic, citric, gallic and meconic acids, and their salts. [illegible] acid. Esters. C [illegible] series. Isomerism [illegible] acid, phenols, aniline. Alkaloids.

The paper on chemistry which the visitors would like to see set "would consist of, say, five questions on general chemistry, of which three at least must be answered, and four questions on carbon compounds, of which, say, two must be answered. This would make a total of five questions to be answered, a number not greater than is required at present by the Irish Board and which can be easily answered in two hours.

It is very important that the kind of question set should be such as will involve thought and reasoning on the part of the student and not merely the exercise of memory as to the properties and preparation of a small selection of chemical substances."

ORAL EXAMINATION IN CHEMISTRY.

In each of the four bodies visited there was an oral examination in chemistry.

At the English Conjoint Board all papers not much over or under 40 per cent. of the full value involved an oral examination. At the three other bodies all candidates were examined orally. In Scotland it was the main feature of the examination and was admirably conducted.

The visitors would like to see at the English Conjoint Board an extension of the oral examination to a larger proportion of the candidates than is the case at present, although those gaining a high value and those gaining a hopelessly low value for their papers might be exempt

On the other hand, they "approve the way in which the oral is used at the English Conjoint Board—namely, to check the paper marks, confirming or altering them according to the judgment of the examiner."

PRACTICAL CHEMISTRY.

The visitors assert that "the only one of the four examinations visited which makes an approach to a satisfactory examination in practical chemistry is that of the English Conjoint Board. One simple salt is to be identified by chemical tests one simple salt is to be prepared and shown up and an account of the work done is to be written [illegible] ed at this or at any of the [illegible] and the Conjoint Board in [illegible] *by chemical tests*, while at [illegible] candidate merely applies a few tests to a solution in a few minutes as part of the *viva voce* examination"

The visitors "would very strongly recommend that all examining bodies should follow the English Conjoint Board in requiring a preparation to be made and exhibited, and that in all the separation and identification of two metals from a mixture of their salts or oxides [illegible] e base and one acid by [illegible] king experiments, even [illegible] in view of the medical [illegible]

CONCLUSIONS OF THE EXAMINATION COMMITTEE.

[illegible] visitors' report as one of great value and [illegible] f the suggestions made by the [illegible] e question of retention of biology [illegible] ination, suggest that the Council should appoint a special committee to consider the questions raised in this report and report to the Council.

Sir VICTOR HORSLEY, seconded by Dr. FINLAY, moved the adoption of the report with reference to the Scottish Conjoint Board.

This motion was agreed to after some slight alterations had been made on the suggestion of Dr LINDSAY STEVEN.

On the motion of Sir VICTOR HORSLEY, second by Mr. JACKSON, the Council expressed the opinion that the examination in practical chemistry was insufficient.

The report on the examination of the Irish Conjoint Board was also adopted.

Dr. NORMAN MOORE thought the Council should speak of the examination as "satisfactory" rather than as "sufficient." He moved to this effect, but his motion failed to find a seconder and consequently dropped.

Mr. BRYANT then moved in connexion with the third report—

That a joint committee consisting of members of the Education and Examination Committees be appointed to consider the questions raised generally in the report of the Examination Committee on the primary examinations of the three Conjoint Boards and the Apothecaries' Society of London and to report to the next session of the Council.

Sir CHARLES BALL seconded the motion.

Mr. BROWN took exception to this special committee being confined in the manner proposed to members of the Education and Examination Committees.

Sir VICTOR HORSLEY moved as an amendment—

That the Council go into committee of the whole Council on the report of the Examination Committee.

He thought that with this report before them members of the Council were in a position to discuss this important question and to put into a definite form suggestions for changes in the curriculum.

Mr. TOMES seconded this amendment.

Sir WILLIAM THOMSON, supporting the motion, said that the proposals made to the Examination Committee were new to them and, of course, they were far-reaching and important and the committee felt that it was bound to seek assistance before dealing with them. There were the bodies themselves to consult before they decided to leave out biology as a definite subject on which lectures were to be given and he did not think it would be wise to decide the matter off hand.

Dr. WINDLE said that it was not proposed to leave biology out of the curriculum but merely to treat it by a different method.

Dr. MCVAIL supported the appointment of the special committee as the wisest course in all the circumstances.

Sir VICTOR HORSLEY said that he merely proposed that the Council should now discuss the opinions which had been placed before it in these reports and it could afterwards have a committee to draw up proposed changes.

On a vote being taken the amendment of Sir Victor Horsley was rejected by a large majority and the motion of Mr. Bryant was thereafter carried.

The following members were nominated to the special committee—viz., Mr. Bryant, Mr. Young, Dr. McVail, Sir Charles Ball, Sir John Batty Tuke, Dr. Norman Moore, Dr. Windle, Dr. MacAlister, and Sir William Turner.

The Case of Mr. Henry Jacob Bradlaw.

The Council next proceeded with consideration of the charges against Henry Jacob Bradlaw, in regard to whom the Dental Committee had found that the following facts were established by evidence, or admitted, at its meeting on Oct. 21st:—

(*a*) Henry Jacob Bradlaw was registered on July 21st, 1891, as in practice before July 22nd, 1878, and his address in the Dentists Register is 4, Harrington-street, Dublin. (*b*) Being a registered dentist he has sought to attract a practice by a system of advertisements in pamphlets and circulars distributed from house to house and in other ways and in newspapers containing his name, address, and qualifications and prices charged and eulogies of his dental work. The advertisements were circulated in Ireland and in London. By the Irish advertisements persons in need of dental aid were invited to consult Mr Bradlaw professionally at places in Dublin and Belfast, where he was stated to be in constant personal attendance, and in the London advertisements persons were invited to consult him at 146, Inverness-terrace, London, where he was stated to be in constant daily attendance. In the opinion of the committee the advertisements are of a nature discreditable to a professional man. In order to carry on the practice as advertised Mr. Bradlaw has associated himself in dental practice with his brother, David Barnett Bradlaw, a medical practitioner residing at 146, Inverness-terrace, and authorised and permitted David Barnett Bradlaw to carry on the advertised dental practice there in the name and on behalf of him (Mr. H. J. Bradlaw) and to personate him in so doing.

Mr. R. W. TURNER, who represented the complainants, the British Dental Association, said he understood that Mr. Bradlaw wished to make a statement to the Council. He did not know what that statement was to be but he should submit that the charges were proved, that they were even more extensive than those made against his brother (Mr. D. B. Bradlaw), inasmuch as they referred to advertisements not only in London but also in Ireland.

Mr. BRADLAW said that he was very sorry indeed for what had been done. He did not intend to transgress the rules in any shape or form and he trusted that in future his conduct would merit the approval of the Council.

The PRESIDENT: But the committee states that the advertisements are discreditable to a professional man.

Mr. BRADLAW: I have done simply what hundreds of others have done

The PRESIDENT: You express regret at having done this but are you going to stop it?

Mr. BRADLAW: I have stopped it to a certain extent. I have stopped anything that Mr. Turner pointed out was objectionable. I have stopped all advertising except my name and address and fees and attendance in the newspapers.

Questioned as to his registered address, which it was pointed out was that of the Irish-American Dental Surgeons, he explained that he left 4, Harrington-street, seven years ago, since when he had carried on business at 78, Harcourt-street.

In answer to Mr. TURNER, Mr. BRADLAW stated that the Irish-American Dental Surgeons' business had been turned into a limited liability concern a week or two ago. He held one £1 share in it but neither his wife nor his brother held a share. There were only seven shareholders, each having only a £1 interest. All of them were registered dentists and the practice was carried on by Mr. John James Blaikley, who had conducted it before the business was turned into a limited concern. It did not issue pamphlets and he did not know that it would do so.

The PRESIDENT: Were you the prime mover in the construction of this company?

Mr. BRADLAW: No, Mr. Blaikley was. I joined because I thought there was no harm, that it was a perfectly *bonâ fide* matter. Mr. Blaikley came to 4, Harrington-street this year.

By Sir CHRISTOPHER NIXON: So far as profits are concerned, I believe no arrangement has been made yet, but I suppose I shall participate in these equally with the other shareholders.

Mr. BRADLAW, answering other questions, explained that the dental practice had been carried on continuously at 4, Harrington-street from the time he left that address. When he was there his father was the tenant of the house but he did not know who the landlord was. He was aware that the Irish-American Dental Surgeons' advertisement followed his in an Irish newspaper but that might be because the newspaper had an alphabetical arrangement for business advertisements.

By Sir VICTOR HORSLEY: He did not allow his brother to personate him at 146, Inverness-terrace, Bayswater. When leaving for Ireland for a few days he asked him to see his patients. He was aware that his brother had been found guilty by the Council of personating him in London but he denied that he authorised his brother to personate him.

After the Council had deliberated in private

The PRESIDENT said: I have to announce the decision of the Council, which is to the following effect—that on the facts found in the report of the Dental Committee it has been proved that Henry Jacob Bradlaw has been guilty of conduct which is infamous or disgraceful in a professional respect and the Council directs the Registrar to erase from the Dentists Register the name of Henry Jacob Bradlaw.

The Case of Mr. William Herbert Ray.

Consideration was next given to the case of William Herbert Ray, in connexion with which the Dental Committee, at a meeting on Nov. 23rd, found that the following facts were established by the evidence:—

(*a*) William Herbert Ray was registered in the Dentists Register on December 31st, 1878, as in practice before July 22nd, 1878, and his address in the Dentists Register is 12, Cecil-square, Margate. (*b*) On the 16th day of January, 1903, the said William Herbert Ray was convicted at the quarter sessions for the borough of Margate of unlawfully and indecently assaulting and ill-treating a certain female named Grace Hennessy on 27th of July, 1902, and was ordered to be imprisoned with hard labour for six months. (*c*) The assault was committed at the house of the accused when he was attending her professionally. (*d*) The conviction was the result of a second trial before the same recorder (Mr. Bargrave Deane, K.C.), the jury having disagreed on the previous occasion. (*e*) The accused denied *in toto* the truth of the charge. (*f*) A petition to the Home Secretary extensively and influentially signed was presented asking for a mitigation of the sentence on the ground that, with the exception of evidence as to Mr. Ray' [illegible] a formal character [illegible] cution was that of give[illegible] l on oath, with a the [illegible] ation and [illegible] be [illegible] at [illegible] ins.' [illegible] g) [illegible] that she had reported the assault to [illegible] ladies whom she accidentally met in the street. [illegible] not produced as witnesses for the prosecution. The accused, in the course of his evidence at the trial, alleged that the ladies did not, in fact, exist, but he suggested that the prosecutrix had been got hold of by two men who were his enemies and who had induced her to bring this false charge against him in order to cause his ruin. Mr. Ray admitted to the committee that this suggestion had no foundation in fact and had been put forward by him at the last moment very unwisely and without the knowledge of his legal advisers.

Mr. RAY, in answer to the PRESIDENT, said that he had already said all he could say: he stood there an innocent man; he was innocent of the charge made against him. He was a married man. His wife was living and he had three children grown up. He had been in practice at Margate for 31 years and never before had any charge been made against him. The petition to the Home Secretary was signed by a brother of Sir Frederick Treves, the medical men of Margate with (he thought) two exceptions, Canon Fleming, the Bishop of Salisbury, several of the Margate magistrates, and others. Since resuming practice his patients had returned to him and he was getting more work than ever before.

In answer to a MEMBER,

The PRESIDENT explained that the girl connected with the case was a domestic servant, 19 years of age, and in the habit of going to Margate in the summer. She had put herself under the charge of Mr. Ray.

Mr. RAY stated that he saw her on four consecutive mornings and also on the Sunday evening when it was alleged the offence was committed. She should not have come that evening. She had been told not to come back unless she took a certain draught which she did not take.

The Council deliberated on the case. On the readmission of the public,

The PRESIDENT, addressing Mr. Ray, said: The Council has given much consideration to your case and the decision is as follows—that it will take no further action in the matter, therefore your name remains on the Register.

The Case of Mr. James Grant.

Another dental case followed. It was that of James Grant and in regard to it the Dental Committee at an inquiry on Oct. 21st found that the following facts were established by evidence:—

(a) James Grant was registered as in practice before July 22nd, 1878, and his address in the Dentists Register is 15 Chatham-place, London. (b) The West Central Dental Institute, Limited, is a limited joint stock company formed and registered by an unqualified, unregistered man named John Panhans for the object of carrying on the practice of dental surgery and the business and profession of dentists. The said John Panhans had before the formation of the company been convicted of the offence of practising as a dentist and the company was [illegible] n under the name of the company [illegible] id James Grant entered into the [illegible] of the person or persons who [illegible] to the company in order that he [illegible] alified man by whom the dental [illegible] ant's defence was that he did not know that he was doing wrong and that he left the service of the company at the end of the week which followed a second conviction of the said John Panhans for practising dentistry in the name of the company.

Mr. Grant was called but did not appear.

The PRESIDENT: Mr. Grant appeared before the Dental Committee but he is not here to-day to avail himself of the opportunity of making a statement.

Mr. R. W. TURNER, on behalf of the British Dental Association, said that the association regarded this as a singularly bad case because it was an attempt on the part of Mr. Grant to defeat the ends of justice. At the police-court it was opened for the defence by Mr. Arthur Newton that a conviction could not be sustained because there was a qualified man on the premises to do the work. Mr Grant was put into the witness-box to substantiate that statement, but he failed in cross-examination because it was clearly shown that Panhans did all the work. If Mr. Grant did not know that he was doing wrong under the Dentists Act he knew that he was being put forward by the defence in order to defeat the ends of justice. Therefore, as it was such a bad case of covering he asked the Council to inflict the extreme penalty.

The Council having deliberated for a few minutes

The PRESIDENT said: I have to announce that the Council has instructed the Registrar to erase from the Dentists Register the name of James Grant.

Restoration to Register.

Consideration *in camerâ* of an application for restoration to the Medical Register, adjourned from Nov. 28th, 1902, resulted in the announcement that the Council had directed the Registrar to restore to the Register the name of Mr. James Jerome Mackay, 190, Stockwell-road, S.E

The Council adjourned.

SATURDAY, NOV. 28TH.

The Council resumed work to-day, Sir WILLIAM TURNER being in the chair.

The Council and the Two English Royal Colleges.

Mr. ALLEN, Registrar, read the following communications from the Royal College of Physicians of London and the Royal College of Surgeons of England, viz.:—

Royal College of Physicians, London, S.W.,
Nov. 19th, 1903.

[illegible]

Sir William Turner, K.C.B.,
President of the General Medical Council.

"The delegates appointed by the Royal Colleges beg to report that having fully considered the letter of the President of the General Medical Council they recommend that the following reply be sent to the President:—

'The Royal Colleges thank the General Medical Council for the expression of their opinion respecting the courses of study and the [illegible]

Royal College of Surgeons of England, Lincoln's Inn Fields,
London, W.C., Nov. 20th, 1903.

[illegible] r has [illegible] the [illegible] l the [illegible] ions [illegible] cept [illegible] il to [illegible] neral [illegible] and [illegible] been [illegible] ttees [illegible]

I am, Sir, your obedient servant,
S. FORREST COWELL, Secretary.
Sir William Turner, K.C.B., President, General Medical Council.

Sir VICTOR HORSLEY moved:—

That the Council do represent to His Majesty's most honourable Privy Council that the courses of [illegible] physics and biology, to be gone [illegible] tions for registration from the I [illegible] Royal College of Physicians of [illegible] Surgeons of England, are not s [illegible] persons obtaining such qualification of the requisite knowledge and skill for the efficient practice of their profession.

He desired the Council to note that he was not raising the general question of preliminary scientific education; he was simply asking the Council to conclude one item of business. Neither was he asking the Council to institute any comparison between one examination and another or between one licensing body and another. He hoped that the Council would adopt his motion in order to put an end to a business which was really 13 years old. He might say that the profession outside this Council was watching this matter pretty closely and it expected that this would end in a determination as to who was the supreme authority in medical education. The profession recognised that the Council in this matter was merely endeavouring to carry out its statutory duties and that it had been trying to do so with every leniency and courtesy that could be exhibited. He had seen this leniency and courtesy exhibited for over five years and by every shift and method the two English Royal Colleges had tried to prevent the Council from discharging this statutory duty. The duty of this Council was to inquire into the courses of study and examination required by the examining bodies and if it found that these were insufficient then it was lawful for the Council to represent the same to the Privy Council. In this case the English Royal Colleges were, as it were, in a contumacious position, and the time therefore had come when the Council must ask the central government, the Privy Council, to decide between them. The Royal College of Physicians of London after having taken over six months to consider the facts laid before them by the Council sent a letter which was no answer to the Council. This Council asked for comments upon the remarks made by the visitors but received none. The Royal College of Surgeons of England replied very fully. It entered very fully upon the report of the visitors and it said that not only were the statements of the visitors inaccurate but the examination was sufficient. The College directly and contumaciously challenged the opinion of the Council. The refusal of an answer by the Royal College of Physicians of London aggravated, in his opinion, the refusal of the two bodies to meet in any way the Council at that stage of the negotiations. In July he moved a similar motion which the Council in its generosity refused. On that occasion the Council requested the President to furnish to the Colleges the reports which revealed the existing condition of affairs and an attempt was made to have a conference with the two bodies. The conference never met because the Colleges refused to confer and treated the Council with absolute contempt. They were therefore contumacious.

Dr. PYE-SMITH rising to a point of order asked whether it was permissible for a member to use the word "contumacious" in this connexion.

The PRESIDENT (to Sir Victor Horsley): In what sense do you use the word?

Sir VICTOR HORSLEY: In the ordinary sense.

Dr. PYE-SMITH: What do you mean?

Sir VICTOR HORSLEY: The ordinary meaning of contumacious is a person refusing to recognise someone placed in authority over him.

The PRESIDENT: You have used the word. Go on now.

Sir VICTOR HORSLEY: Do not use it again is, I suppose, what you mean. He thought, however, that the medical profession would understand the meaning of the word and it was the medical profession he represented and not the interests of a single body. There was a constitutional point to be decided here. The Council was statutorily recognised by the central government as the head authority in medical education. That position had been challenged by the English Royal Colleges and he submitted it was the duty of the Council to go to the central government and obtain from it a final judgment in the matter.

Dr. MACKAY, in seconding the motion, called attention to the words of the Act under which the Council was entitled to act. These words, he said, stated clearly that if it appeared to the Council that the course of study and examinations to be gone through in order to obtain any qualification were not such as to secure the possession by persons who obtained the qualification of the requisite knowledge and skill for the efficient practice of their profession it should be lawful for the Council to represent the same to the Privy Council. The English Royal Colleges insisted upon a course of study and examination and this Council had found that both were insufficient. He admitted that it might become the duty of the Council to examine into the circumstances of other bodies but at present it had before it a serious case and it was its duty to represent the matter to the Privy Council. The General Medical Council existed for the protection of the public and if it did not make a representation to the Privy Council it must have a very serious and important reason for not carrying out its duty. The Council had endeavoured to see whether the English Royal Colleges were prepared to carry out its wishes and they had refused even to enter into a conference on the subject. While he recognised the valuable services to medical education of these bodies he thought the Council did right in asking them to this conference It would have been of great value for the parties to meet together and to discuss the whole question of the relationship of examinations to courses of study. As to the existing regulations of these bodies they made it possible for a student to spend six months of an annus medicus in a grammar school or technical college. Now he did not think that the representatives of the two Colleges would care to defend such a regulation In all the circumstances he thought the Council must go to the Privy Council and have the matter settled. He did not anticipate the very serious results that some people did; he thought that the Privy Council would bring about that conference which the Council had failed to bring about and if that was the result he thought it would be most fortunate.

Mr BRYANT rose not to discuss the motion but to point out that the question of authority as between the General Medical Council and the Royal Colleges was not the issue that was before them at all and that the Royal Colleges having stated that the Council's opinions would receive the respectful consideration of both Colleges it was fairly well known that they meant that and the subject was under the fullest and closest consideration. In these circumstances he did not think the General Medical Council could say that the Colleges in any way were attempting not to follow out the suggestions which had been made. Where defects occurred they were anxious to remove them and so improve the education. He would not discuss the prudence or wisdom of the General Medical Council going to the Privy Council but if the Council went the Privy Council would say the Colleges were considering the subject and he, as the representative of the Royal College of Surgeons, would say here that his College was considering the subject and would continue to consider it until defects were removed.

Dr. NORMAN MOORE, in response to an appeal by Dr. Bruce, said that he had already spoken on this subject several times and there was the further difficulty of speaking at all on the point. He had, and every Fellow of the College of Physicians had, the greatest respect for the General Medical Council in the discharge of the functions committed to it by Act of Parliament, but when particular subjects had been in controversy for a considerable time there might be used phrases that would cause irritation and might seem disrespectful, though disrespect was not in the mind of the speaker. Sir Victor Horsley used the word "contumacious." They need not spend time discussing the etymology of that word. The dictionary gave the meaning of it as "swelling against, haughty, resisting legitimate authority"—that was what Sir Victor Horsley meant—and, in law, "wilfully disobedient to the orders of the court." That implied that there was a court which was vested by the law with certain powers and which had exercised these powers and then it was contumacious to disobey it. He would not go into the subject as to whether the General Medical Council was such a court or not. Let them suppose for a moment that the General Medical Council possessed all the powers that its most extreme advocates wished it to possess—let them suppose that it had all the power which Sir Victor Horsley would invest it with if he happened to become a dictator in this country—that it could advise all the licensing bodies to study such a subject for such a length of time, then what were its orders, what edict had it issued for the first year's subjects of study? Just before the Council met that afternoon members had been discussing how it should inform itself on this very subject. It had issued no edict. These Colleges were not contumacious, and why? Because they were responsible for their conduct. Under the terms of their charters and Acts of Parliament it was their duty to determine the courses of study and what should be the examinations in these. They could not transfer that duty to any other body. If the General Medical Council wished to have it transferred to other bodies let it issue an order. He thought the Royal Colleges were perfectly right in declining a conference. The only object of a conference was to secure a satisfactory conclusion. No satisfactory conclusion could have been arrived at in this instance by a conference. What were they to confer about? The delegates from the Colleges could only tell that the Colleges were considering. Sir Victor Horsley said something about the Colleges using every shift and method for delay. That was unjust. It was a kind of expression which never should have been used. In transactions with a man they always assumed that he was acting in a proper way and he said that it ought to be the same with universities and other bodies. There could be no other base. Sir Victor Horsley said there was the question as to which was the supreme authority as to medical education. He did not think there could be any question as to that. As to the public duties the Colleges had under their charters they must either discharge these or disfranchise themselves. They maintained that they were discharging these duties honestly and to the best of their ability. The General Medical Council had the undoubted right to criticise any examination but the Council was in this position: it said the fact that the General Medical Council had certain rules regard to the courses of study and examination red the people obtaining the Colleges' qualifications not possessed of the requisite knowledge and for the profession. To use such an expression e earlier studies was a twisting of words What ought Sir Victor Horsley meant was this—that in inion and that of the General Medical Council the ges' earlier examination might be improved. The ssion could not mean more than that. It was carrying beyond their true sense to think that it did. If the of the General Medical Council was to ascertain ier certain powers were given to it by Act of Parliament l not know any other way in which it could ascertain han by applying to a court of law. The Council did [illegible] egligence, or corruption, or any- xercise of the powers they had, [illegible] Council was absolutely supreme d only to issue an order, and if that was the law it be obeyed. But he doubted if any members of ouncil thought so. They felt that the Council had instituted by Act of Parliament and might wisely ise powers which were not dependent on law but for the general welfare of the public. When it so it should be supported by all the licensing bodies. at sense it was supported by the Royal Colleges; received its criticisms with respect, they considered in the utmost possible way, they attached all the tance that must be attached to such a body as the cil, they endeavoured to make use of these opinions ds perfection—there was nothing perfect on earth—of courses of study and examinations. That was their on. But they were not in a position to receive orders this and that and to be declared contumacious because presumed to discuss and thoroughly to investigate ons, however valuable these opinions might be.

CHRISTOPHER NIXON, while mentioning that he was vour of chemistry, physics, and biology being removed de the medical curriculum, contended that in order cure uniformity throughout the kingdom there must be itral body to lay down the law. Dr. Norman Moore that the General Medical Council had not issued an . But what about the regulation with the words roved by the Council"? That was an edict in respect stitutions in which the first year's subjects were taught h the Royal Colleges in very strong language refused to Then came the question of the registration of nts. So that since the words "approved by the cil" were introduced it might be said that the l Colleges had put the General Medical Council at nce. The whole profession, he ventured to say, had attention centred on this one question: Had the ral Medical Council any authority beyond giving a pious opinion? That was the reason why the time arrived when the Privy Council should determine whether General Medical Council had been exercising the powers erred upon it or whether it had been exceeding these rs.

. BRUCE rose to move an amendment. He said he ght the action of the Royal Colleges had been in many opposed to the real interests of medicine and surgery, e could not follow Sir Victor Horsley in moving to go e Privy Council in this matter, because he was opposed aking action against these recalcitrant bodies on two nds. He was convinced that if the Council attempted amper the education given in the intermediate schools of country it would be dealing a blow to the reform of ndary and elementary education which was now in the His second objection was involved in the result of [illegible] almly at [illegible] way of [illegible] y asked n to take. He moved:—

> [illegible]
> our [illegible] of the Council respecting courses of study and the examina- in [illegible] tic [illegible] of [illegible] reconstructed examination the Council resolves to defer in the ntime taking any further action.

r VICTOR HORSLEY contended that this was not a com- nt amendment to his motion There was nothing in it would not be covered by the "previous question."

The PRESIDENT ruled otherwise and called on Dr. Pye-Smith who had consented to second the proposal.

Dr. MCVAIL, interposing, suggested that if the proposal could be put Dr. Pye-Smith should give the Council evidence of the Royal Colleges' reconstructed examination because there was no such evidence before the Council.

Dr. PYE SMITH was afraid he would not be able to do so as he could only say that the Colleges had assured the Council that the matter would receive their respectful attention and that already changes had been made in the curriculum.

Sir VICTOR HORSLEY: No references are made to changes in the curriculum in what we have before us. These must be contained in some official documents and these documents ought to be in our hands.

Dr. NORMAN MOORE: The Colleges have written to the Council to say that all *that the Council has forwarded to* them will receive respectful consideration. That means that the fullest consideration shall be given to every remark.

Sir VICTOR HORSLEY: Dr. Pye-Smith says that the curriculum is changed. Is it a fact?

Dr. NORMAN MOORE: If I could utter a single word which would convey my meaning I should never make a speech. If the Royal Colleges could discuss this subject in a quarter of an hour they would no doubt do it, but it requires a great deal of time and consultation with a great number of people. It has been the custom to consult the teachers when any changes in the curriculum were under consideration. Certain principles of change have been adopted but the details have not been worked out. I cannot communicate these because they are not yet published in complete form So soon as they are they will be sent here.

Sir VICTOR HORSLEY: I referred myself to Dr. Pye-Smith.

Dr. PYE SMITH said that he had told Sir Victor Horsley all he knew. What he first rose for was in recommendation of the amendment to plead once more for the cause of peace. He doubted the wisdom of receiving medical students from schools but the matter was one on which there might be difference of opinion There had been difference of opinion in the College of Physicians as there had been difference of opinion at the General Medical Council. The opposite view, however, was held by Dr Bruce, it was held by Dr. Lombe Atthill, and held and vindicated again and again by Sir William Gairdner, and he was sure that such a consideration would induce the Colleges to see that there was a difference of opinion. As to the conduct of examinations, the final conclusion of the visitors inspecting the examinations on the primary subjects was that of all examinations some had some good in them and some had defects He should admit that the examinations of the two Royal Colleges had defects, but in this respect the Royal Colleges did not differ from other institutions. For all parties concerned with these examinations the results of deliberations of this Council were most admirable and useful. With regard to the conference, he regretted that the invitation of the Council was not accepted, for it was felt that when such charges as had been made—that the *Council's suggestions had been put on one side and that the* Council had been disobeyed—were made they were likely to raise a little of the spirit of independence, and if they were to have peace it would be well to lay aside words as to whether the *Colleges* had, as they said, the power to do what they had done. The question of appealing to the Privy Council was the question of, Who is master? and he ventured to deprecate the Council embarking on such questions. He thought he was justified in that if he referred to the time when the Council had a special meeting to discuss this same question and when a most important motion was proposed in the morning and run away from in the afternoon. That, he thought, was reason *for the Council to postpone action. If the Council* did not go to the Privy Council what would it depend upon? They should depend upon their influence. Surely they ought not to submit the rival claims of Colleges and Council which were quite open to discussion to the adjudication of lawyers who knew very little about them and their objects. He thought that doing so would be an irretrievable mischief and in any case the result would be most disastrous.

Dr. WINDLE thought that the last part of the amendment was confused and that *the words were rather cumbersome*, and he suggested that it might be better to make it read:

> That in view of the reconsideration of the whole subject by the Royal Colleges the Council resolves to defer taking any further action until the examination has been again inspected under the new regulations.

Dr. Bruce and Dr. Pye-Smith were willing to accept this modification of their proposal.

Dr. Windle agreed with Dr. Pye-Smith that the question now before the Council ought not to be the question of the jurisdiction of the Council, but he thought that they were a little sick of hearing of charters and Acts of Parliament. What was the best way of getting the medical education improved at the present time? Was it the best plan to go to the Privy Council or was it not? In his opinion it was not. They would advance better on the lines of the amendment. He was sorry that the Colleges did not see their way to meet the Council in conference, but the communication did not really invite them. They had the option expressed in "if desired," and apparently they thought it was not desired. He was not defending the Colleges but placing them on the line that existed. As to the Colleges' regulations, were the Colleges attempting to alter these? New regulations proposed by the College of Surgeons had already appeared, having been published in The Lancet of Nov. 21st. Among them was one proposing a minimum length of course. That was one thing the Council wanted and if instruction was given to this extent and in proper institutions the Council would have all that they could ask for from the Colleges. It was also proposed that study at an institution other than a recognised medical school should be counted for not more than six months of the curriculum. As far as the scheme went the College of Surgeons placed itself on the lines of the London University which did not require any evidence as to where a student had received education. If, therefore, the Council quarrelled with the Royal Colleges they would also have to quarrel with the London University on that point. So far the Colleges had gone to meet the Council and this was not the end of their consideration, but only a stage in their journey. Therefore he ventured to think that the Council would obtain the improvement in medical education that they desired and that was what he wished and not the determination of—Who is to be master? He should hope that the Council would adopt the same policy as in the case of the University of Oxford. Respecting that university they had a report which was not satisfactory and they agreed that they should do no more about it until a new inspection was made. He hoped it would be possible to put the Colleges' new regulations into operation as soon as possible and after inspection of the examination under them they should see what was done. Until they saw what the changes amounted to he thought that they were not in a position to go to the Privy Council.

Mr. Brown intimated that if the motion went to a division he should vote for it.

Sir Charles Ball said that the spirit in which this matter had been approached that day compared very favourably with what had been previously heard on this subject. But the representatives of the Colleges, while representing their desire that the fullest consideration and the fullest information should be given to the General Medical Council, had yet left it to another member of the Council to read from a medical journal what had actually been accomplished at the Colleges. It would, he thought, have added much to the force of what the Colleges had done if they had had it stated by one of the representatives of the Colleges. He went on to contend that the dragging on of this question during the last five years had been very injuriously affecting medical education. In Ireland they did not know where they were, for when asked what they were to do they could only give the answer that what the Conjoint Board of England did that they should do. That was certainly not a satisfactory state of affairs and if Sir Victor Horsley's motion brought a climax he should support it. He did not like the amendment which postponed settlement indefinitely until the reconstructed examination of the Colleges was reinspected. The examination had not been reconstructed yet and the Colleges might delay reconstruction as long as they chose.

Dr. Little regretted that the term supreme authority had been used so often that day. He hoped all would remember that the General Medical Council did not claim to be the supreme authority: the Privy Council was the supreme authority. They must thank Sir Victor Horsley for raising the issue, but he should vote for the amendment for three reasons—namely: (1) that he observed on the part of several members of the Council a disposition to change the character of their views; (2) that he wished to continue negotiations, for if the General Medical Council went to the Privy Council it should have to put very specific charges against the Royal Colleges at a time when the whole question of education was in such a condition that great changes might soon occur; and (3) that he felt persuaded they should get to an end of the matter by continuing negotiations sooner than by doing what was proposed—that was, "withdrawing our ambassador."

Dr. MacAlister felt convinced that the information which had been laid before the Colleges since July last had had very considerable weight To many of the Fellows of the Royal College of Physicians that information was new. Although he had not been present at the critical meeting—at any of the meetings—he knew that all the documents had been placed in the hands of all the Fellows and he knew enough to say that a very genuine change was in progress. That change, he had no doubt, would be accelerated by what had taken place since and he had no doubt that so soon as the last stages were complete a communication would be made to the General Medical Council which would be satisfactory to all who had the interest of medical education at heart.

Sir William Thomson asked Dr. Norman Moore if he could give the Council any idea as to when they would have a definite reply from the Colleges.

Dr. Norman Moore replied that it would be out of his province to fix any date. The committees having the matter in hand would go on continuously until they had arrived at the conclusion. He was sure the Council could not wish for more.

Sir William Thomson thought the reply could be a little more satisfactory. He should like to know from Dr. Norman Moore, with his knowledge of how things were going on, whether the Council would have a definite answer from the Colleges by next session or, say with certainty, in 12 months.

Dr. Norman Moore said he should think himself from the present state of the work that perhaps two more meetings of the joint committee might conclude its work and perhaps one meeting more of the committee of each College, with perhaps a final meeting of the joint committee. He thought three or four months sufficient for such meetings. He was not quite certain whether the work could be ended by March next but he thought that substantially it would be concluded before the Council's meeting in May next.

Mr. Brown asked Sir Victor Horsley whether in view of that statement he would withdraw his motion If the matter was to be determined by next session he felt sure that many members of the Council would hesitate to vote for the motion.

Dr. McVail wished to propose that the further consideration of the motion and amendment should be postponed until next May.

The President: Don't you think the amendment does that?

Dr. McVail did not think so. It was, of course, quite open to the President to take a vote on the amendment, but if that was done he (Dr. McVail) could still propose postponement. He thought that Sir Victor Horsley, having been victorious all along the line, might be satisfied with having driven them into the position in which they now were.

The President: I do not know exactly how we stand with regard to this question.

After a brief conversation

Dr. McVail thought that Sir Victor Horsley had gained a substantial victory in this matter and that the Royal Colleges were now clearly going to come up to what the General Medical Council required, but they were only endeavouring to save themselves from the formal appearance of having acceded to the recommendation of the General Medical Council. So far as he was concerned he was quite willing to accept that. It had been got with great difficulty. He thought that now the Colleges were disposed to give way. Dr. Pye-Smith gave them hints of something going on behind the doors, Dr. MacAlister told them that the Council's documents had had considerable weight with the Fellows of the Royal College of Physicians, and then Dr. Windle had quoted from The Lancet a report of action taken, which action Dr. Norman Moore did not repudiate. Therefore he thought that substantially the Council had achieved what it had been contending for so long. The whole thing was to be finished by the Colleges in four months or so and they should have before them the whole case at their next meeting. He thought that in the circumstances Sir Victor Horsley might withdraw his motion.

Sir VICTOR HORSLEY wished to speak on the amendment because he must be satisfied that the authority and the influence of the General Medical Council, which had been challenged not merely by the English Colleges but by other bodies which had followed them, would be restored. Dr. Pye-Smith said that the quarrel was a petty one. But the scientific education of medical students was not a petty matter at all but the most serious question any man could take up. There were points concerning the scientific education of students on which they had not been satisfied. The first of these was the registration of students, the whole of which had been destroyed by the action of the Colleges. Where was the registration of students to come from? Nothing had been said as to the scientific education of the students being brought back to what it was before 1901. On the contrary, the English Colleges had said that they had their own register. Then as to the reconstruction of examination, what finality was there? They were told that change in the curriculum was in process, but there was not a word as to where the courses of study were to be carried on, nor a word on the central point which originated this discussion. The original contention of the Council was that it should have a supervisory control over the teaching institutions. The Council had not surrendered that control and he asked what had they to show that the Council would be allowed supervision in the future. He had not heard a word which showed that the Council's supervision would not be challenged. The Colleges said they reserved to themselves to say what courses of study and examination should be adopted. They had given a tardy acknowledgment that their examination and courses of study were not what they professed in this Council they were. They had acknowledged that change was in progress. And they would come in May next and say: "Do you approve of that?" They were going to shelve the Council again and he asked members not to vote for the amendment thinking that they had settled the whole question. He could not see that he should be justified in the interests of medical students or justified in the interests of those who had sent him to the Council in withdrawing his motion and he hoped that for similar reasons the Council would not accept the amendment.

The PRESIDENT proceeded to arrange for a vote on the subject and Dr. BRUCE, at the instance of Sir VICTOR HORSLEY, substituted in the last part of the amendment the words "courses of study and examination" for the words "whole subject." Sir VICTOR HORSLEY also wanted registration of students to be included, but Dr. NORMAN MOORE objected that that was not a question under debate. The amendment was finally arranged as follows:—

> That the General Medical Cc [illegible]
> munications set out in the minu [illegible]
> of Physicians of London of the [illegible]
> [illegible]
> [illegible] ology are to
> [illegible] that in view
> [illegible] nation by the
> [illegible] further action
> [illegible] ler the new
> regulations.

On a division 16 voted for this amendment and 12 against it. One Member did not vote and two were absent.

The PRESIDENT: The amendment has now become a substantive motion.

Mr. BROWN: I beg to move—

> That the consideration of the motion be postponed.

Sir JOHN BATTY TUKE seconded this proposal The terms of the motion, he said, were humiliating to the Council.

Dr MCVAIL remarked that the motion committed the Council to take no action in the matter until after the inspection of the examination under the new regulations The position was absurd and he thought the best course would be not to adopt Dr. Bruce's proposal but to postpone the matter.

Dr. BRUCE objected to the words "humiliating" and "absurd" In the interests of peace he urged that they should go on. He pressed his proposal.

Sir VICTOR HORSLEY hoped that in the interests of real peace Mr Brown's motion would be accepted.

The Council divided on Mr Brown's proposal. On a show of hands the PRESIDENT announced that 13 voted for it and 13 against it. On names and numbers being called it was found that 14 voted for it and 13 against it. One member did not vote and three were absent.

As Mr. Brown's motion was thus carried the question was postponed *sine die* but it may be raised again in some form in the session of May next.

The Council adjourned.

MONDAY, NOV. 30TH.

The Council met to-day, Sir WILLIAM TURNER being in the chair, and before it rose concluded the work of the session.

The Inspection of Final Examinations.

The first business was to receive from the Examination Committee reports on the inspection of the following final examinations—viz.: the English Conjoint Board, the Irish Conjoint Board, the Apothecaries' Society of London, and the Apothecaries' Hall of Dublin (July, 1903). These reports were in each case presented by Mr. BRYANT, chairman of the Examination Committee.

English Conjoint Board.

The following was the report of the committee on the examination of the English Conjoint Board, viz.:—

The final examination in medicin [illegible]
January, 1903 commenced on Tues [illegible]
the 30th. 228 candidates were exar [illegible]
56 per cent., passed and 101, or 44 [illegible]
[illegible]
teacher.

The general arrangements for the examination were similar to those [illegible]
[illegible]
wifery is three for each paper, the maximum in each being ten. The [illegible] the answers of several candidates whose oral [illegible]
[illegible] had followed and pronounced the

[illegible] the examiner on the case
[illegible]
specified disease.

In clinical surgery the candidates under the five years' regulations were examined orally for 30 minutes on at least two cases, each of which they had been previously allowed to examine by themselves for five minutes Several candidates were examined on more than two cases and were then taken over a wide range of surgical subjects. At the conclusion of the clinical examination each candidate was required to write at a side table a short description and diagnosis of two microscopical specimens of new growths or crystals, and ten minutes were allowed for this. The visitor and inspector state that they were impressed by the thoroughness of this examination and the uniformity in the standard of answering that was required In clinical medicine and surgery the cases were numerous and excellent In the oral examination in medicine and surgery a different pair of examiners were allotted to each group of candidates, and both examiners examined each candidate; in medicine one of the two for ten minutes in urine testing and the other for another ten minutes in pathological specimens. The oral examination in surgery was conducted at the Royal College of Surgeons at five tables. Every candidate was examined at two tables, ten minutes at each table. Excellent pathological specimens were upon all the tables and upon two or three of them each candidate was questioned.

In practical surgery each candidate was examined for 15 minutes upon a large collection of surgical instruments, splints, and in bandaging, as well as upon surface surgical anatomy and the lines of incision for operations No operations upon the cadaver were practised. T[illegible] to the visitor and inspector to set the standard [illegible]

The exam[illegible] id diseases of women was pronounced by the visitor and inspector "a most excellent and practical one." Every candidate was examined for ten minutes by one of the examiners alternately at two tables—at one table in midwifery and at the other in gynæcology. Upon each table (four in all) an ample supply of pathological specimens and instruments was provided, as well as female pelves, "dolls," pessaries, &c. To pass this examination each candidate must have half-marks.

In medicine the maximum marks are 50. To pass the candidate must get 25. In surgery the maximum is 30 and to pass he must obtain 15. In midwifery the maximum is 20 and pass marks 10. The visitor and inspector were not satisfied with the system of marking adopted by the Colleges and refer to the former report for the reasons of their objection. On page 19 of the present report they illustrate the defect of the system adopted and point out that where the maximum mark for a subject is five and a candidate in the opinion of the examiners deserves anything more than one whole number, up to five, he is given the benefit of the fraction and awarded the next number above; and as the pass mark is 50 per cent. it follows that a candidate who in the opinion of the examiners just qualifies to pass must secure 3 or 60 per cent. They also support this view by an example. They express the opinion that the maximum marks awarded at any portion of the examination should not be less than ten. The visitor and inspector in their observations at page 17 of the report pronounce the arrangements for the different parts of the examinations to have been excellent. There was not the slightest hitch or delay in any part of the examination, and considering the large number of candidates that were examined the organisation that ensured such results must be looked upon as perfect. They express their satisfaction that the time devoted to the examination in clinical medicine and surgery has been extended to 30 minutes and that the examination in clinical surgery is now as good a one of its kind as could be desired. They regret that the recommendation made in their last report "that in addition to the oral examinations candidates should be required to furnish a written report of at least one medical, as well as of one surgical, case has not been adopted." This committee are of this opinion. They likewise regret the absence of, and can see no difficulty in providing for, a special examination in ophthalmic surgery such as is so general in Dublin, and express an opinion "that no one should be granted admission to the Medical Register who did not give evidence by examination of having had adequate ophthalmoscopic training and who could not show at least that he was able to delineate the vessels on the fundus oculi," which opinion this Examination Committee endorses. The visitor and inspector also regret that there is no examination in operative surgery on the cadaver.

The Committee of Management of the Conjoint Board state that they have no remarks to make on the report but they inform the Council that inasmuch as some remarks are made by the visitor and inspector in reference to the examination in operative surgery, clinical, ophthalmic, and aural surgery, and to the scheme of marks, they have suggested to their respective Colleges that the Court of Examiners might be requested to take these remarks into consideration. Upon this suggestion the two Royal Colleges have arranged to act. The final conclusion of th report, that the final examinations of the Conjoint Board of England are "sufficient," is satisfactory to this committee.

Mr. BRYANT, seconded by Dr. FINLAY, moved the adoption of the report.

Mr. BROWN moved an amendment to the effect that the further consideration of the report be postponed until after the remarks of the Court of Examiners had been forwarded to the Council.

Sir VICTOR HORSLEY seconded this amendment.

Dr. MCVAIL thought this amendment should not be pressed. This report, he said, was quite as satisfactory as others they had adopted and when the work of inspecting the final examinations was completed they could have a report on the whole series and on this have a debate upon points of detail.

Dr. MACALISTER said that the bodies here had done all they could do at this stage—namely, to refer the criticisms passed on the examination to the Court of Examiners for their consideration.

The amendment of Mr. Brown was rejected and the report adopted.

Irish Conjoint Board.

On the examinations of this body the Examination Committee reported as follows, viz. :—

The visitation and inspection of the Irish Conjoint Final Examinations of the Royal Colleges were completed in May, 1902, and the carefully considered report of the visitor and inspector upon the examinations contains criticisms and suggestions which demand serious consideration by the bodies inspected. The final decision of the reporters must, however, be acceptable to this committee, for after viewing the examination as a whole they write: "We are of opinion that it is a fair and carefully conducted one and that as regards its sufficiency it fulfils the requirements of the Medical Act."

In the report by the committee of management adopted by the councils of the two Royal Colleges on Nov. 6th. 1902, we are assured that the recommendations of the visitor and inspector "are being carefully considered by the committee of management who are now drafting the details of the method of conducting the examinations" of a revised curriculum which was adopted by the Colleges in July last since the visitation and inspection. As in the case of the University of Dublin, this Irish Conjoint Board divides its examinations in medicine and surgery into two parts and as the visitor and inspector had not inspected the first part the committee recommend the Medical Council to pursue the course it adopted last May with respect to the University of Dublin.

The visitation and inspection of Part II. of the final examinations of the Conjoint Board of Ireland was made in April and May of 1902 and was reported upon by this committee in November of the same year. In this report the Council was recommended by the committee to direct that Part I. of the final examination should be visited and inspected and in accordance with this wish the visitor of this Council carried out his instruction in April, 1903, but unfortunately without the assistance of the inspector, Sir G. Duffey, who was too ill to attend.

When the report of Part II. of the final examinations was made in November, 1902, it was known that a "revised curriculum" was being drafted with the details of the method of conducting the examinations. This scheme, as a whole, was adopted by the Conjoint Colleges in July, 1902, and is now in force. The new curriculum requires five years of study at a medical school, except in the case of candidates who have studied for one year in institutions recognised by the Conjoint Board of England for the teaching of chemistry, physics, and biology. The visitor, in his report upon Part I. of the examination, tells us that "all the suggestions contained in the report of the inspector and visitor in May, 1902, had been accepted and acted upon."

That the examinations in pathology, therapeutics, and forensic medicine were carried out in strict accordance with the new regulations of the Conjoint Board in a painstaking and thorough manner. That the examination in pathology was at once practical and scientific with abundance of morbid specimens and of microscopic preparations, also that the successful candidates displayed a good knowledge of the subject. "In the departments of therapeutics and forensic medicine there was also an ample supply of specimens." "The marking was by no means lenient." The visitor finally reported that the oral examination was a good one and "sufficient."

No opinion was given by the visitor upon the written papers. "Owing to a misunderstanding on the secretary's part the papers asked for by the visitor were not forwarded"

To this Examination Committee the conclusion of the visitor after his inspection of Part I. of the final examination, "that the oral examination was a good one and 'sufficient,'" seems to support the following conclusion by the visitor and inspector after the visitation of Part II. in May, 1902:—"We are of opinion that it is a fair and carefully conducted examination nd that as regards its sufficiency, it fulfils the requirements of the Medical Act."

On the motion of Mr. BRYANT, seconded by Dr. BENNETT, the report was adopted.

Society of Apothecaries of London.

The report respecting this society was as follows:—

'The final examinations of this corporation, which are held monthly, are divided into two sections, the first composed of three parts and the second of two parts. Candidates may take up both sections together but are advised to take these sections separately—Section 1 at the end of the fourth year, Section 2 at the end of the fifth year. Section 1 must be passed before Section 2.

Section 1 consists of three parts:—

Part I. (A) includes a written examination in the principles and practice of surgery, surgical pathology, and surgical anatomy; an oral examination in surgery, surgical pathology, operative manipulation, surgical anatomy, instruments, and appliances. Part II (B) includes written and oral examination in the principles and practice of medicine, including therapeutics, pharmacology, and prescriptions; pathology and morbid histology, forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III. (C) which may be taken with Section 2, includes written and oral examination in midwifery, gynæcology, and diseases of new-born children; examination in obstetric instruments and appliances.

Section 2 consists of Part I. (A) clinical surgery; Part II. (B) clinical medicine and medical anatomy. Candidates may enter in Section 2 for A and B together or separately.

EXAMINATION IN SURGERY.

The general arrangements for the examination were satisfactory. Each candidate—there were 11—was examined by the four examiners in the clinical, practical, and oral examinations. The paper on surgery contained six questions, one of which was upon eye surgery. Four of them, and no more, were to be answered. Two questions were given on pathology and two on surgical anatomy, but only one of each had to be answered. So out of ten questions on surgery six only had to be answered, and for the surgical paper three hours were allowed. The questions were good. Except in doubtful cases the answers were read by one examiner only.

For the clinical examination, in which each candidate was examined for 20 minutes, there were sufficient cases, both in number and character, and the visitor pronounced the examination to have been a fair and searching one. This committee would, however, desire to see the length of time allowed for this part of the examination on clinical surgery prolonged for another ten minutes; half an hour is a minimum as to time for such an important subject as clinical surgery.

The examination in practical surgery included an examination for ten minutes at each of two tables, one devoted to surgical anatomy and operative manipulation and the other to instruments and bandaging. The instruments and appliances available were good and sufficient and three living models were available.

The oral examination in systematic surgery and pathology was pronounced by the visitor to have been a good and searching one. Each candidate was examined for ten minutes in surgery and for another ten minutes in pathology. The minimum pass mark in this examination was in each subject 50 per cent. The method of marking was judicious, being based on the percentage system. Of the 11 candidates who presented themselves for examination in surgery seven passed and four failed. There is apparently no provision in the regulations requiring evidence of study during the period for which a candidate is referred. This is to be regretted, for such requirement should always be made and enforced.

EXAMINATION IN MEDICINE.

This examination was conducted on the same lines as that in surgery and the arrangements for it were excellent.

Written examination.—Three papers were given at this examination:

one on medicine and therapeutics, containing six questions, four of which must be answered; three questions in pathology, two of which must be answered; and four questions [illegible] paper two hours. *The questions on the three papers the visitor pronounced to be unexceptionable.* The marking was likewise satisfactory to the visitor.

In the clinical examination each candidate was assigned a case out of the many which were present and half an hour was allowed for its examination. The candidate was then given another half hour in which to write a report on the case, including its diagnosis, prognosis, and treatment. One of the examiners also gave the candidates an oral clinical examination on another case which lasted 15 minutes. This examination was supervised by the two examiners. The examina- [illegible] candidate was sent to a table upon which was a selection of recent and of museum morbid specimens, upon which he was examined for 15 minutes. He then passed to a second table upon which were microscopes and a variety of slides illustrating urinary sediments, parasites and different pathological conditions and was examined for another 15 minutes. For a third quarter of an hour he had to examine a specimen of urine and to report the result in writing. The visitor pronounced the examination itself to have been satisfactory, although the knowledge of pathology displayed by the majority of the candidates was indifferent.

In the written examination on midwifery there were in the paper four questions, but only three had to be answered. In that on *gynæcology there were two questions, but only one had to be answered.* The oral examinations in medicine, forensic medicine, and in midwifery and gynæcology were conducted at three tables, one for each subject, and each candidate was under examination for 15 minutes at each. On the medicine table was a volume of plates of skin diseases—apparently no morbid specimens. On the forensic medicine table there were specimens of poisonous drugs, chemical reagents and apparatus, and samples of cloth acted upon by acids. On the midwifery table a female pelvis, fœtal skull, a few museum specimens, and some obstetrical instruments. Close by there was also a "phantom," which was used once. The visitor expresses no special opinion upon this part [illegible] [illegible] and seven [illegible] In midwifery [illegible] concluding observations of the visitor pleasure is expressed at the great care and [illegible] is conducted. He [illegible] but does not note [illegible] in the surgical paper. He expresses an opinion that the art of prescribing should have more attention at this examination. His conclusion, however, is that the final examination is "sufficient." This report is signed only by William Bruce, visitor, on account of the sad illness and irreparable loss of our Inspector—Sir George Duffey. To this committee the conclusion of the visitor that the examination is "sufficient" is satisfactory.

On the motion of Mr. BRYANT, seconded by Dr. BENNETT, the report was adopted.

Apothecaries' Hall of Ireland.

The committee reported on this Hall as follows, viz.:—

There were two candidates for the first examination, one for the second, one for the third, and five for the final. At the first examination one came up for chemistry and was rejected. The second came up in osteology, pharmacy, and biology and passed in all three subjects. The inspector reported the examination in practical pharmacy to have been exc- [illegible] tion came up in anatomy [illegible] rejected in the first two [illegible] medica. The candidate fo[illegible] jurisprudence and hygien[illegible] candidates for the final examination had been up before. Out of the four who came up in medicine one passed and three were rejected. Of *the five who came up in surgery one passed and four were rejected.* The successful candidate was said to have passed in surgery very creditably by the surgical examiners. Of the four who came up in midwifery one passed and three were rejected. Of the two who came up in ophthalmic surg[illegible]

The inspector repor[illegible] satisfactorily conducte[illegible] clusions upon his th[illegible] worthy of attention. [illegible] Hall express pleasure in the fact that the inspector reports that the examination was thoroughly and satisfactorily conducted and state that the Inspector's observations relative to the marking will receive full consideration.

Mr. TICHBORNE took exception to certain statements in the report and it was arranged that he should be given an opportunity of appending an explanation.

The report was agreed to like the others.

In Camerâ.

The Council sat for over an hour in private. On the readmission of the public

The PRESIDENT announced, first, that the Council had resolved to restore to the Medical Register the name and qualification of Mr. Charles Augustus Bynoe, Licentiate of the Royal College of Surgeons of Edinburgh; and, secondly, that the President had been authorised to communicate with the President of the Local Government Board with regard to death certification.

Preliminary Examinations.

Sir JOHN BATTY TUKE submitted a report from the Education Committee on certain preliminary examinations as follows:—

The Education Committee have had before them detailed reports by Dr. M'Cormick on the results of his inspection of the examination papers set and marked answers sent up by candidates, in the medical preliminary examinations held by the Educational Institute of Scotland and the Conjoint Board in Ireland. These bodies have also submitted to the committee full particulars of their *methods* of marking and other details of their systems; and these, with Dr. M'Cormick's comments have enabled the committee to form a satisfactory judgment on the scope and standard of the examinations in question.

As regards the examination of the Educational Institute of Scotland the improvements already effected or about to be introduced are so satisfactory that the committee feel justified in anticipating that during the next year the examination will have attained in every respect the standard desired by the Council. In future the examination in Latin and Greek, like that in French and German, will be conducted entirely by means of unprescribed books. Steps have also been taken for the appointment of examiners who have had experience of the standards and methods of the Scottish university preliminary and leaving certificate examinations, and these examiners will meet to revise the papers and marks conjointly before deciding on the passing or rejection of the candidates. In order to give the committee an *opportunity of observing* the effect of these and other changes it is proposed to continue for the year 1904 the recognition hitherto extended to the examination. It is hoped that next year the com- [illegible] examination definitively on the [illegible] the Irish Conjoint Board certain improvements in regard (1) to the distribution of marks between different branches of the several subjects included, (2) to the preponderance assigned to the oral examinations in classics and mathematics, and (3) to the requirements of a minimum standard in *each* of the subjects of examination, have still to be carried out. The [illegible] year 1904.

He moved that the report be received and entered on the minutes and adopted. In answer to a question by Dr. McVail he added that the College of Preceptors had adopted the system of unprescribed books with an alternative. He had no definite information as to whether the Irish Board would do the same but the matter would again be brought under their notice.

Dr. NORMAN MOORE seconded the motion.

Sir CHRISTOPHER NIXON thought that the Irish Conjoint Board would be unable to come into line with others in regard to the use of unprescribed books so long at least as the Royal University of Ireland was allowed freedom on the subject.

Dr. MACALISTER said that what the Council had been doing was to proceed upon the joint report of the three referees who had dealt with this subject. In that report the examination in unseen translations was held to be the ideal form, but there was no condition laid down that the system should be universally applicable. The Council was aiming at it but it could not lay down a universal rule.

Sir CHARLES BALL believed that the recommendations now made would produce an examination satisfactory to the Council. The examination was satisfactory to the Conjoint Board.

Sir J. W. MOORE said that as the representative of the Royal College of Physicians of Ireland he should like to express his recognition of the great courtesy and consideration shown in regard to the Irish Conjoint Board's preliminary examination. He could assure them that the committee of management of the Conjoint Board had spared neither time nor trouble nor expense in trying to improve the examination in every possible way and to bring it up to the proper standard. He thought that committee had achieved a large degree of success and he had no doubt that it would give the fullest consideration to any suggestion coming from the General Medical Council. He did not know what the Conjoint Board would do if this examination did not exist. The Board was anxious in every way to carry out the views of the Council's Education Committee.

Mr. TICHBORNE took exception to the penultimate sentence in the paragraph relating to Ireland, contending that against the understood arrangement that examinations in general knowledge should not be under the charge of medical corporations it was proposed to perpetuate the preliminary examination conducted by the Conjoint Board of Ireland. He moved to this effect.

Mr. Jackson seconded this amendment which was rejected by 18 votes to 3.

The report was then adopted.

Sir John Batty Tuke next submitted a report of the Education Committee on a communication from the Apothecaries' Hall, Dublin. The communication and report thereupon were as follows:—

40, Mary-street, Dublin, Nov. 19th, 1903.

To the President of the General Medical Council.

Dear Sir,—I beg to inform the President of the Medical Council that we, the Apothecaries' Hall of Ireland, intend on the 1st of the year 1904 to resume our preliminary examinations in arts.

It is intended, for the purpose of conducting these examinations, to appoint qualified university non-medical graduates.

When our arrangements are completed we shall be pleased to facilitate any inspection the Medical Council desire.

I remain, dear Sir, yours,

Robert Montgomery, M.R.C.S., Secretary.

This is an intimation that the authorities of the Apothecaries' Hall, Dublin, intend next year to revive the preliminary examination in arts which, in deference to the express wish of the Council, they have for many years discontinued. The committee are unaware of any circumstances which would justify so serious a reversal of the educational policy which, at the Council's instance, has been generally adopted by the licensing bodies, including the Apothecaries' Hall. The committee, therefore, strongly deprecate the proposed re-establishment of a preliminary examination conducted by a professional body which has no special relation to questions of general education. Should such an examination be, notwithstanding, instituted for candidates seeking the Licence of the Dublin Apothecaries' Hall it will rest with the Council to decide whether it should be recognise[illegible] gistration of students in general. Such [illegible] a practical way the arrangements of othe[illegible] to preliminary examination.

Accordingly the committee, in view of the grave educational issues involved, do not recommend that the Council's approval should be given to the step contemplated by the Apothecaries' Hall, Dublin.

He (Sir John Tuke) hoped that this report would be received, entered on the minutes, and adopted. Most members of the Council, he said, were aware that upwards of 30 years ago all the medical corporations gave up examinations in general knowledge with the exception of the two authorities in Dublin. The Apothecaries' Hall, however, in 1885 also gave up its examinations in arts and no reasons had been put forward why a retrograde step should now be taken. To revive an examination which had always been deprecated and objected to by the Council at large was different from sanctioning what might be spoken of as a sort of remnant in the case of the Conjoint Board, which, he believed, would get rid of its arts examination at the earliest possible moment after a suitable examination was established to take its place.

Dr. McCall Anderson seconded the adoption of the report.

Mr. Tichborne said that the Apothecaries' Hall, Dublin, had not wished to undertake the preliminary examination in arts. To reinstitute examinations would mean a great deal of responsibility to the Hall; it would not mean money, it might mean loss. But they were forced into taking the step by the fact that the Conjoint Board had formed a cordon round the Hall that prevented any one of the students taking the Board's preliminary examination going to the Hall for their medical education. So long as such a system existed he did not see how the Hall could carry on its work successfully. He understood that the Conjoint Board did not contemplate giving up its examinations in arts and if that was so the Hall wished to persuade the General Medical Council to inspect any examinations it might institute. Legally, by its Act of Parliament, as well as by the Medical Act, the Hall was entitled to conduct examinations in arts and it wished to be on all fours with the Conjoint Board. If it was necessary for the Conjoint Board to have the conduct of examinations in arts it was necessary for the Hall. If the Hall re-established such examinations the General Medical Council had no reason to suppose that they would not be properly conducted. The Conjoint Board had not been particularly successful with these examinations and the Hall thought it would be advantageous to have the liberty to inaugurate a system of its own.

Mr. Brown thought it would be only just that the Hall should be placed on the same footing as the Conjoint Board, especially as it had statutory rights to conduct examinations in arts.

Sir William Thomson protested against any assumption that there was hostility in this matter between the Conjoint Board and the Apothecaries' Hall. The only reason why the Conjoint Board did not give up its examinations in arts was that nothing had been instituted yet to replace them. The Conjoint Board was ready to give up its examinations to-morrow if something suitable were substituted.

Sir John Moore had heard with extreme surprise that the Apothecaries' Hall was, or should be, on all fours in this matter with the Conjoint Board. The Apothecaries' Hall had no school. There was no *raison d'être* for preliminary examination at the Apothecaries' Hall; it was simply going there to pay for examination.

Dr. McVail was prepared to vote for the adoption of the report, but, after all, the vote would be merely a piece of pious opinion on the Council's part. The Apothecaries' Hall could do exactly as it thought fit and what was here almost rebellion against the Council's wish was what had occurred in connexion with other subjects and other bodies. The gateway having been once opened it was not likely that only one party would pass through it. It was very unlikely that in future they would not have other bodies acting independently on lines of their own. He thought it was a great pity that at this time of day after all the discussions they had had that they should be brought back to the very first steps of their long, long journey.

Mr. Tichborne remarked that if the Conjoint Board was complimented on acceding in spirit to the wishes of the General Medical Council he must remind the Council that the Apothecaries' Hall had acceded to the Council's wishes in act.

The President: Why are you going out of your good way? Why, after so many years, are you going back?

The report was adopted.

Reports of the Council's Proceedings.

Dr. Norman Moore had on the programme a notice to move—

That it be referred to the Executive Committee to consider and report to the Council upon the possibility of making arrangements with the medical journals for an authorised report of the discussions of the Council.

On being called on he said: At this very late hour of the session I ought perhaps to withdraw this motion. It must take some time to discuss but I will explain in a sentence or two what was proposed. I fully recognise the excellence of the reports of the debates of the Council which appear in the medical journals. They are excellent but, of course, all reports of that kind must contain errors, very serious errors; and I thought it might be worth while if the Council considered whether it could enter into an arrangement which would, of course, cost the Council some money but which might provide in some way for greater precision. It might be to our advantage. I propose in a future session to present this but for the present I ask leave to withdraw it.

Leave was given and the subject dropped.

The Pharmacopœia Committee's Report.

Dr. MacAlister moved that the following report should be received, entered on the minutes, and approved:—

The Pharmacopœia Committee beg leave to report that from May 24th to Nov. 24th the number of copies of the British Pharmacopœia sold was 711, and of the Indian and Colonial addendum 123. The total numbers disposed of are thus: of the Pharmacopœia, 34,591; of the addendum, 664.

The committee held a special meeting on Oct. 30th for the purpose of considering in detail the questions raised by a digest of criticisms, prepared by their direction by Mr. W. Chattaway. At this meeting a number of details were considered and certain were selected as deserving of inquiry in preparation for the revision of the Pharmacopœia.

The final instalments of the investigation on the solubilities of drugs, conducted in the Research Laboratories of the Pharmaceutical Society of Great Britain by Professor Greenish, have been forwarded by the council of the society to the committee. These will, as in other instances, be published for general information. The series of memoirs on this subject constitutes a valuable addition to the data at the committee's disposal.

Professor Dunstan, of the Imperial Institute, has made substantial progress with the examination, begun last year, of the pharmacopœial tests for arsenic. In view of the laborious character of the inquiry the committee propose that a second and final grant of £50 should be made to Professor Dunstan to enable him to complete the work and to present it in a form that may be immediately available for the preparation of the next issue of the Pharmacopœia.

Other researches, initiated in conference with the representatives of the pharmaceutical societies of Great Britain and of Ireland, are in progress.

Dr. Norman Moore seconded the motion which was agreed to.

On the motion of Dr. MacAlister Sir J. W. Moore was appointed a member of the committee in place of Dr. Lombe Atthill.

Public Health.

Dr. BRUCE, seconded by Sir CHARLES BALL, moved that the following report by the Public Health Committee should be received and entered on the minutes :—

The committee had the following communication from the War Office submitted to them at their meeting on Nov. 27th :—

War Office, London, S.W., Nov. 26th, 1903.

SIR,—I am directed by the Secretary of State for War to submit the following recommendation of the Advisory Board for Army Medical Services, namely, that certificates granted by the sanitary officer of the [illegible]

[illegible]

health administration.

I am to request that this communication may be placed before the Council, which is, I understand, now in session.

I am Sir, your obedient servant,

The Registrar, General Medical Council. EWD. WARD.

After maturely considering the different points in connexion with the foregoing communication [illegible] the precedent of Gibraltar, [illegible] be added to the list of recog[illegible] [illegible] tory instruction required [illegible] opportunities of acquiring a knowledge of the working of the public health laws in relation to a civil (as distinguished from a military) [illegible]

Sir JOHN BATTY TUKE wished to enter his protest against the introduction of such important reports as this at the fag end of the session. There was, he must admit, considerable jealousy with reference to the Public Health Committee because it had been whittling down the conditions under which the Council started some years ago. He had not had time to look at what this particular report meant and it might mean a great deal more than appeared on the surface.

Dr. NORMAN MOORE: We should consider this report very thoroughly.

Dr. BRUCE: Are you against it going on the minutes? Do you not think it would be better to consider it when it has been placed on the minutes?

Mr. BROWN: Withdraw it and bring it up next session.

Dr. MCVAIL: Any debate on it should take place before it is entered on the minutes If it is to go back it should go back without being put on the minutes.

Dr. MACALISTER: I think it should go on the minutes. The letter from the War Office is dated Nov. 26th, so there has not been much time lost in getting it through. As to the substance, I do not see that there is any reason why the report should not go on the minutes

On a division the motion to receive the report and to enter it on the minutes was carried, 18 voting for it.

Dr. BRUCE then asked the Council to approve of the report.

Sir JOHN BATTY TUKE desired to know what the Council's responsibility would be under it. He said he had always noticed that Government communications came in at a time when they must be shoved through, but he saw no reason why if the Bombay command was recognised the Madras and Bengal commands should not also be recognised. He wanted to have some reasons for his vote in regard to the Bombay command and he had none.

Dr. WINDLE moved that consideration of the motion should be postponed. He did not think matters should be rushed through at the last moment and this one could well stand over until the next meeting of the Council.

Dr. NORMAN MOORE had no hostility to the report but he quite agreed that there was something in it which required great consideration and one consideration was the precedent of Gibraltar, for when they came to other parts of India there would, if the report was adopted, be the precedent of Bombay. He thought the Council ought to be quite sure that the training for an Indian command was equivalent to the training required of a man who was to hold a public health appointment in England. If it were so he should support the report; if not he should not vote for it.

Dr. MCVAIL considered it unfair to the War Office to say that its letter was sent out only on Nov. 26th, for it actually, though in an informal form, had been sent on the 6th. While it looked very sudden on coming before the Council at the last moment the Council was partly to blame for that because of the manner in which arrangements were made to hold meetings of committees. He must support the application made by the War Office; he did not see how they could refuse it seeing that they had already recognised Gibraltar. If they were not on the down grade in respect to the Bombay command application, they were expanding; and Mr. Power had told the committee that if the application was granted there would follow applications from the India command and from the navy. He would vote for the adoption of the report.

Dr. BENNETT considered that it would be very undesirable to postpone this matter.

On a vote Dr. Windle's motion for postponement was rejected by 13 to 10.

Dr. MACALISTER thought that instead of adopting the report it would be better to pass this motion :—

That Bombay be added to the list of recognised military districts, that the report of the Public Health Committee be communicated to the Secretary for War, and that his attention be specially called to the last paragraph of the report.

Dr. BRUCE made no objection and Dr. MACALISTER'S proposal, seconded by Dr. NORMAN MOORE, was agreed to.

Final Examinations of the Scottish Universities.

Dr. MACALISTER moved :—

That the Executive Committee be requested to arrange at its meeting in February for the inspection of the final examinations of the Scottish Universities next year.

He remarked that it would take some care to find an inspector so capable and much appreciated as Sir George Duffey had been and he thought the Executive Committee should have some time in which to look around before it made an appointment.

Dr. BRUCE seconded the motion which was at once agreed to.

The Apothecaries' Hall of Ireland.

On the motion of Dr. MACALISTER, supported by Sir J. W. MOORE, it was resolved :—

That the Executive Committee be requested to arrange for the appointment of a visitor or inspector for the examination of the Apothecaries' Hall, Dublin, and that the inspection take place from time to time as the President directs.

Dr. MACALISTER next called attention to a communication from the Apothecaries' Hall, Dublin, which showed that :—

[illegible]

He suggested that the reply should be to the effect that under the Medical Act, 1866, the Council had no power to pay the expenses of an examiner.

This was agreed to.

Report of Students' Registration Committee.

Sir HUGH BEEVOR submitted a report from the Students' Registration Committee showing how certain applications for exceptional registration as students or for the antedating of the commencement of professional study had been dealt with, and recommending that the Swansea Technical College (day classes) should be added to the list of recognised institutions approved by the Council.

The report was adopted.

A Vote of Thanks.

Sir HUGH BEEVOR, seconded by Dr. NORMAN MOORE, moved :—

That the thanks of the Council be given to Dr. Windle and to Professor J. Campbell Brown for their visiting all the first medical examinations of the licensing corporations of the United Kingdom and reporting upon them individually and collectively.

The motion was passed and the PRESIDENT wished personally from the chair to thank the two gentlemen named for their great services and for having given the Council so admirable a summary of the whole subject of the visitation of the first medical examinations.

Annual Returns.

On the motion of Mr. BRYANT, seconded by Sir CHARLES BALL, the following report was received and entered on the minutes and the recommendation in the last paragraph of it was adopted:—

The Executive Committee having considered a return showing the answers of the licensing authorities in regard to the practicability of the proposed changes in the presentation of the information laid before the Council in the annual tables, obtained pursuant to the following resolution of the General Council adopted on May 23rd, 1903:—

That the report of the Examination Committee upon the desirability of obtaining additional information from the various licensing bodies for use in the preparation of the Annual Table (*a*) showing results of professional examinations, which was received by the Council and entered on the minutes and appears as Appendix XXII. of the volume of minutes for 1902, be referred to the various licensing bodies and that they be requested to inform the Council whether it is practicable to give the information in the form suggested in Table I. of that report.

RETURN.

Answers received from the licensing bodies in response to a request for information as to whether it is practicable to give the information in the Annual Table (*a*) in the form suggested in the Examination Committee's report.

Name of body.	Table I., showing results of examinations according to subjects for qualifications primarily admitting to Register.	Table II., showing number of repeated rejections.
R. Coll. Phys. Lond.	No serious difficulty.	Time and labour required would cause considerable inconvenience.
R. Coll. Surg. Eng.	No objection.	Would involve too great expenditure of time and labour.
Apoth. Soc. Lond.	Practicable.	—
Univ. Oxford.	No particular difficulty.	—
Univ. Camb.	No (except in certain groups of subjects).	—
Univ. Durh.	Practicable.	—
Univ. Lond.	No difficulty.	—
Victoria Univ.	No objection.	—
Univ. Birm.	No difficulty.	—
Scottish Conjoint Board	Can supply the information if desired.	—
R. Coll. Surg. Edin.	Can easily supply.	Table I. will show.
Univ. Edin.	Practicable.	—
Univ. Glasg.	Practicable but modification suggested.	Form suggested for this.
Univ. Aberd.	Ditto.	—
Univ. St. And.	Practicable.	—
Irish Conjoint Board (answering also for both Colleges).	Will be happy to comply.	At present impossible.
Univ. Dubl.	Practicable.	—
R. Univ. Irel.	Not possible. Passes in separate subjects not awarded.	—

Resolved: That this return be remitted to the Examination Commi[illegible]

[illegible] having carefully considered the replies fro[illegible]s, find:—

I [illegible] of the University of Cambridge and the Royal University of Ireland all the licensing bodies are prepared to give the information as to the results of professional examinations for qualifications primarily admitting to the Register in the form of Table I. suggested by the Examination Committee. The difficulty with both these Universities is identical—namely that they do not recognise the passing in any one of the subjects forming a group for purposes of [illegible] didate passes in all the others at the same [illegible] information given as to passes and rejectio[illegible] jects grouped together for an examination. As will be seen by the footnote appended to the suggested table this difficulty has been provided for. For example, at the final examinations a candidate may obtain good marks in medicine but low ones in surgery and midwifery; he is therefore rejected for [illegible] to present himself again for examina[illegible] e subjects in which he was deficient. [illegible] that he should appear as a rejection in the separate columns for the sub[illegible] wifery. Acting upon this principle [illegible] in preparing the table from information received from these Universities in [illegible]

[illegible] bodies (the Universities of Glasgow and [illegible] passes and rejections in botany and zoology separately and not combined under the general heading of biology.

III. That the replies received indicate that it is practically impossible to obtain the suggested information as to repeated rejections. This the committee regret as they consider the information, if obtainable, would be distinctly valuable.

The committee therefore recommend that for the future the annual returns showing results of professional examinations for qualifications registrable under the Medical Act, 1886, should appear in the form suggested in their previous report, with the addition to Table I. of columns for the subjects botany and zoology.

Mr. BROWN, on the ground that it was impossible at the end of the session to get the full opinion of the Council, with the consent of his intended seconder, Mr. JACKSON, withdrew for the present the following motion, of which he had given notice:—

That copies of the returns which have been officially furnished to the Council relating to the competitive examinations for vacancies in the department of the Royal Navy and for commissions in the medical staff of His Majesty's Army and in the Indian Medical Service, held in January, May, July, and August, 1903, be sent to the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the Royal Colleges of Physicians and Surgeons in Ireland, and that their attention be directed to the large percentage of rejections at the examinations referred to of candidates who held the diplomas of the Conjoint Boards of Scotland and Ireland.

End of the Session.

Mr. BRYANT proposed that now that the whole business was disposed of they should express to the President their warm thanks for the kind and able way in which he had conducted them through an anxious session. The work, he said, had gone pleasantly and with less difficulty than usual.

Sir J. W. MOORE, as the junior member of the Council, seconded the proposal.

The PRESIDENT having acknowledged the compliment,

The Council rose till May, 1904.

EPSOM COLLEGE.

AN extraordinary general meeting of the governors of Epsom College was held at 37, Soho-square, London, on Nov. 26th, the President of the College, Lord ROSEBERY, being in the chair.

The Treasurer, Dr. CONSTANTINE HOLMAN, proposed the following motion:—

That in accordance with the powers given under Section 12 of the [illegible] College Act of 1894 the name of the college [illegible] College" in lieu of "The Royal Medical [illegible] in documents issued from the office in London the following words, so far as is practicable, be added immediately after the title: "Established in 1855 as a public school with a Royal medical foundation."

He said that he regretted the absence of the chairman of the council of the college, Sir Joseph Fayrer. In his (Dr. Holman's) opinion the proposed change of name would benefit to an enormous extent both the medical profession and the college. He explained that the college was founded for all classes but offered special advantages to the sons of medical men. Provision was made for 50 foundation scholars elected from the necessitous orphans or sons of medical men. There were 50 pensioners chosen from the most necessitous cases in the medical profession as vacancies occurred. There was a curious insistence on the part of the public and also on the part of some members of the medical profession to regard Epsom College as a class school. Mr. Propert who founded the college never intended it to be a class school or a charity school, and in support of this contention he read a letter from Mr. L Propert, the son of the founder. The word "benevolent" in the title "Royal Medical Benevolent College" was used by the founder to find the money for building the college and the time had now arrived when the word might very well be dropped. In 1894 some doubt was thrown upon the power of the council to admit all classes to the college. Therefore an amending Act was procured from Parliament to declare the college open to all and also to give the council power to change the name. A pledge, however, was given that in choosing another name the identity of the institution should not be obscured. It had been found that it was the earnest wish of all that the name should be changed and that boys had not been sent to the college simply because of the title containing the word "benevolent." The council therefore proposed the change indicated in the motion he proposed. Marlborough College and Wellington College had large foundations and he did not see why Epsom College should not have the same. The institution was to be a public school with a Royal medical foundation and by using the word "foundation" the college was safeguarded from the imputation of it being a charity. He could see within a measurable distance a very large portion of the sum necessary for this purpose and under the title now proposed the charitable work of the institution would be rendered secure.

Mr. HENRY MORRIS, treasurer of the old Epsomian Club, in seconding the motion, said that he did so because he was an old Epsomian and there was not a single old Epsomian who did not gladly hail the change of title. There was no doubt that there had been among the laity and among a large number of the medical profession an idea that Epsom College was a charity school. It had been a great satisfaction to him to hear read out the letter of Mr. L. Propert, the son of the founder. Boys from Epsom College were made to feel that the college was considered to be a charity because they were asked on saying where they were educated whether their father was still alive or whether he had broken down in health. Questions of that kind could only mean one thing and the imputation was naturally resented. There was no more reason why Epsom College should be called "benevolent" than Marlborough College or other public schools which had foundation scholars. The word "benevolent" applied to an institution was meaningless, or if it did mean anything it implied something objectionable. The word "benevolent" was an abomination as applied to an institution for it inferred nothing but the idea of charity, implying assistance given to people who were absolutely necessitous. It was undesirable to keep this word "benevolent" because it did not fulfil the intentions of the founder and of those who assisted him in the establishment of Epsom College. They need not fear that the funds of the institution would suffer. It was not to be believed that people gave money to any institution because it was called "benevolent"; financial assistance was forthcoming to an institution when it made good use of the money it had.

Four letters from governors of the institution were then read, two being in favour of the proposed change.

The motion was then submitted to those present by Lord ROSEBERY and carried *nemine contradicente.*

Sir WILLIAM S CHURCH, Bart., K.C.B., President of the Royal College of Physicians of London, in moving a vote of thanks to Lord Rosebery for taking the chair, said that they thanked him for coming to that meeting and acting as chairman. They also thanked him as a neighbour, for not only did he reside in close propinquity to Epsom College but he was also a neighbour in a much fuller and nobler sense, placing his help freely at the disposal of the institution whenever it was required.

Mr. CHRISTOPHER HEATH seconded the motion which was put to the meeting by Dr. HOLMAN and carried with acclamation.

Lord ROSEBERY, in reply, said: I am much obliged for the cordiality with which this vote has been received. Long before I was connected with Epsom College I felt deeply that this question of the name handicapped very severely the energy and prosperity of the college. In the first place the [illegible] is the fatal [illegible] stitution in [illegible] so lengthy [illegible] ys marvels, for those who have been connected with the management of this college, whether as treasurers, governors, or as headmasters, that they should have made the college what it is under the great disadvantage of the name. The other disadvantage under which the late title laboured has been called attention to—namely, the inclusion of the meaningless but distasteful word "benevolent." When you come to think of it, there is no reason in the world why Eton, which, in my opinion, holds pride of place among public schools and which I put at the head of all educational establishments, not perhaps in respect of education but from certain other points of view, should not have applied to it the word "benevolent." I hope there are no Harrovians or members of rival schools here to tear me in pieces for putting Eton first but we all have these childish prejudices. There was no reason why Eton should have omitted the words and title we have just discarded. There was no reason why the word "benevolent" should not have been given to Eton, because when Eton was founded by Henry VI. with 70 foundation scholars it was a Royal Benevolent College, and I cannot conceive that anybody will think that Eton College would prosper so well if it were suddenly to add the additional epithets of "royal" and "benevolent" to its name. I say this because I notice in one of the letters of objection sent by one of the governors a lingering regard is expressed for the word "royal." The discarding of the word "royal" does not mean that we are ungrateful or unmindful of the constant proof of the interest of past and present members of the Royal Family in our institution. We are justly proud of it, but so great is the interest that the Royal Family has developed in all public institutions under the reign of our late gracious Queen that almost every institution that does any munificent work would be justified in claiming or retaining the word "royal" for having received some mark of royal interest. That I regard as an immense credit to our Royal Family. Although that be so, would it not be thought absurd if Eton College were suddenly, in memory of the various bounties which it has received from the Kings of England beginning with Henry VI., to say that the word "royal" would be a flattering addition to the title it already enjoys? You can hardly fancy "The Royal College of Eton" and it is even more difficult to imagine "The Royal Benevolent College of Eton." I think that that simple illustration goes to the root of the whole matter and it shows that we are right in discarding these superfluous epithets and adopting the simplest and most direct name, which is the name, too, by which the school has long been popularly known I believe in my heart of heart that this will be a memorable date in the history of Epsom College. I believe the change in the name means a new start, for we have dropped the encumbrances which I think weighed us down, and I who know fairly well as a neighbour the admirable character of the school and of the lads who are trained in it venture in the most sanguine spirit to prophesy that to day will mark a new era of prosperity in the history of Epsom College.

The meeting then terminated.

THE MEDICAL SUPERVISION OF PUBLIC EDUCATION.

NOW that recent legislation has handed over to local councils elected for general purposes of local government the duty of controlling and of directing all public education throughout England and Wales innovations and changes of method are to be expected in various directions, and important questions have arisen and from time to time will have to be decided with regard to the part to be played by the medical profession in the country's education and under the new *régime.* The principles which are likely to be discussed may conveniently be referred to in the consideration of a concrete question which will be ventilated in many places with reference to the medical men who under the school boards, that have passed away, performed such duties as were assigned to them upon their appointment, duties not necessarily alike in different localities. The question is whether school medical officers are to be appointed as to a distinct post or whether the medical officer of health is to combine with his duties as such those of medical officer to the schools controlled by the local authority employing him. In some instances already the medical officer of health has been appointed [illegible] Stovin, to act in the dual capacity, with the consequent displacement of Mr. W. H. Best, medical adviser to the late school board, was urged with considerable vigour by the former gentleman upon grounds of public expediency and of the proper performance of the duties required. His view was not adopted without prolonged argument by the Ilford urban district council and similar discussions have taken place, and, no doubt, will take place, elsewhere. There are many elements of controversy in a subject involving the consideration of "vested interests," of economy, and, most important of all, of efficiency. Before, however, the question of efficiency can be determined or even submitted to argument it is necessary to arrive at a conclusion with reference to another. Previously to deciding by whom the duties of medical officer to a school authority may best be performed that authority must more or less definitely make up its collective mind what those duties are to be, not perhaps with any delimitation of their details but with some distinctness as to their direction and scope. To sum the matter up at the outset, the question is whether the school medical officer is to be mainly a medical officer of health responsible as such for the school, or whether he is to be this and a great deal more. If the duties imposed upon him are to be limited to such as fall within the normal jurisdiction of the medical officer of health there can be no reason of general application why that official should not be appointed or why he should not ably carry out his work and there are obvious reasons which point to him as the right man for the post. It will be more convenient to have one authority to advise the council and to carry necessary measures into effect, uniformity and promptitude of action will be better assured, and the gentleman appointed will have the advantage of experience with regard to an important and preponderating portion of the task assigned to him. The duties of a school medical officer are not, however, in all respects even similar to those performed by medical officers of health acting in that capacity. They must include some, and they may include many, matters with which a medical officer of health has nothing to do. If the latter is the case and the scope of the school medical officer's duties is enlarged the man undertaking both posts may find that there is more to be done than there is time to do thoroughly and that duties have to be attended to for which special study and previous experience would be desirable qualifications.

The Education Acts do not specifically require the appointment of, and assign duties to, medical officers. The Elementary Education Act, 1870, section 35, empowered a school board to appoint necessary officers, and under this section the School Board for London and the school boards for some other large centres selected medical men to perform during the pleasure of the board those duties for which a medical man was necessary—such as the remedying of sanitary defects in schools, the dealing with outbreaks of infectious disease, and the examination of teachers and candidates for school appointments as to their health and of children believed to be mentally or physically defective. The employment of medical practitioners for these purposes was required directly or indirectly by various Acts of Parliament dealing with education. Their further employment for general purposes of school and educational hygiene was a natural development of the educational movement in the hands of boards zealous in the cause of education which found that the advice and coöperation of a medical practitioner making a special study of educational requirements were of considerable practical advantage to them Examples of school boards employing medical officers in this manner are to be found in London, Bradford, Halifax, Manchester, Newcastle, Salford, and elsewhere, but in order to make the study of what may thus be done complete attention must necessarily be directed to the practice prevailing in the United States of America and in various continental countries.

If we assume that it is desired by any educational authority that its medical officer shall be a specialist in school hygiene, charged with the care of its schools and with the duty of making them, so far as his skill and powers permit, efficient educational agents, we shall then find that there are many arguments against the school medical officer being at the same time medical officer of health. The question whether he will have time for the proper fulfilment of the two offices will depend principally on the size and importance of his district and of the schools therein. In small places and outlying districts there may be no difficulty upon this score and the medical officer of health may be on account of his attainments and for other reasons the best man obtainable. In large and populous districts, however, it will be otherwise, and apart from the question of time there are important points to be considered. The medical officer of health and the medical officer of a school authority have to regard the school from different points of view, one of them being concerned with the public health and the other with the health of the school and with the cause of education. For example, where infectious disease has broken out the former by habit of thought and the natural impulse to be on the safe side with regard to the public health may be disposed to close the school at once. The other, having as his first care the progress of education, will rather be impelled to do his utmost to keep the school open, although his desire not to check the education of the children who are in health will cause him to eliminate carefully those likely to prove centres of infection. If through the appointment of two medical men to fill the two offices differences of opinion arise at the time of an outbreak of infectious disease as to the steps to be taken, each can maintain his own point of view and the local authority may have to take the responsibility of deciding between them, but at all events the educational side of the question will not be lost sight of by the one official and the duty of protecting the public health will be enforced by the vigilance of the other. It has already been suggested that such duties as the examination of children who require special educational treatment do not form part of the ordinary functions of a medical officer of health and that the best performance of these duties may most effectually be insured by the employment of one who through inclination and previous training has become a specialist in such matters. The gentleman selected, whoever he may be, and whatever the number of children under his charge, if he is to perform these necessary duties with the utmost efficiency, will have to devote himself to them with constant vigilance. If he is expected to do more, then beyond the exercise of his skill in the detection of defective vision, hearing, and intelligence he will find himself called upon to pronounce opinions upon a variety of other matters, such as the cleanliness, lighting, and ventilation of buildings, the preservation of the health of children with a view to the carrying on of their education, their physical training, and their susceptibility to mental and bodily fatigue, with all the details relating to such subjects. In these circumstances the duties which are akin to those of a medical officer of health will occupy comparatively but a small part of his time and attention, and the others, which are those of a medical expert in education, will demand the exercise of skill, sympathy, and acquired knowledge of a different but no less important description.

It is for this reason that we would urge educational authorities to decide in some measure the nature of the functions which they will expect their medical officer to perform before they make their selection and before they decide to dispense with the aid of those who may have obtained experience and evinced zeal in the performance of those very duties. In case the mere idea of a medical man being employed for school purposes may seem to some a step towards socialism and towards relieving the parent of the care of the health of his offspring it may be pointed out that the school medical officer is for the benefit of the school, not of the child, and in case others who are medical men attending school children may be apprehensive of a tendency to oust them or to discount the value of their services it may be as well to quote in further explanation the concluding paragraph of the annual report recently issued by the medical officer of the London School Board, Dr James Kerr, where he says: "The function of the school doctor in relation to children in the schools is often mistaken even by medical men who should know better. It is no part of his duty to prescribe for or treat any individual case. His work is preventive and in individual cases only applies to matters involving educational questions. He can call attention to the need of glasses but has nothing to do with prescribing them. He may notice the presence of adenoids but takes no part in their removal. On the other hand, his work should extend far beyond mere investigation of the sanitary state of buildings or the excluding of unhealthy or diseased children. The methods of education, requirements of physical exercise, avoidance, particularly in the very young, of overstrain from prolonged fatigue or from improper tasks are all matters in which improvement can only be obtained by the school doctor acting, not as an authority to shut or close, to disturb or interrupt the proper work of the school, but as a counsellor and adviser with a knowledge of school routine and of the requirements for health to assist and collaborate with the teacher and administrator, and it is with this in mind that he should enter any school"

Looking Back.

FROM

THE LANCET, SATURDAY, DEC. 3, 1825.

INJUNCTION DISSOLVED.

TRIUMPH OF THE MEDICAL PRESS.

Court of Chancery, Monday, Nov. 28, 1825.

THE LANCET.

Mr. HORNE said he had a motion to make in the case of "Abernethy *v.* Hutchinson," which he mentioned at the last seal, to dissolve the injunction granted against the defendant, restraining him from continuing to publish, or sell, Mr. Abernethy's Lectures in THE LANCET. At the last seal, the learned Gentleman understood that the Solicitor General, or some other gentleman was to appear for the plaintiff, to oppose the present motion, but he was *now given to understand, that it was not intended to be opposed*, therefore he moved for the dissolution of the injunction, and submitted that he was entitled to his order.

LORD CHANCELLOR: I dissolve the injunction.

We feel confident that this result will be hailed with satisfaction by thousands of our readers, as *the triumph of principle* in a legal struggle, which has been declared by the highest authority in the realm to be one of no ordinary importance, involving, as it did, the rights of Lecturers properly understood on the one hand, and the interests, not so much of a publication, which the Lord Chancellor characterised as one of great utility, as of the whole Medical Profession, and of the public at large on the other.

MEDICINE AND THE LAW.

Blackmail by a Sanitary Inspector.

A SANITARY inspector employed by the city of Westminster has been sentenced to 12 months' hard labour at the Old Bailey for attempting to levy blackmail upon a French restaurant keeper on whose premises he had apparently found certain tinned food which was subsequently condemned and who was thus to some extent in his power. The Frenchman had the good sense to communicate at once with a member of the city council and a detective, by concealing himself and by arresting the blackmailer at the moment when he obtained possession of the bribe which he had tried to extort, was able to prove the case up to the hilt. Blackmail, however, is an offence which it is not always easy to bring home to the culprit even where the intended victim resists and the penalty imposed is by no means too severe for the serious nature of the crime. The occurrence of this incident raises the question whether sanitary inspectors are sufficiently highly paid to secure a class of men who will be superior to the temptations to which their position exposes them. British police and minor officials are probably less corrupt than are those of many foreign nations, but a few black sheep easily gain a bad name for any calling and their example is liable to infect their fellows. Careful selection and supervision, with the prompt conviction and severe punishment of offenders, are necessary in cases where powers such as those exercised by sanitary inspectors are given.

An Extraordinary Medical Impostor.

Convicted under the name of Hubert Part for bigamy a man named John Thompson Cubbin had his true name and history disclosed by the police at Liverpool assizes before receiving from Mr. Justice Ridley a sentence of five years' penal servitude. Born at Chorley in humble circumstances and having been at one time a timekeeper in a colliery, he had for some time pursued a career characterised by fraud and lust, representing himself in many places as a medical man, of which offence he had been convicted, as well as for obtaining jewellery and money by false pretences. He had been through at least one ceremony of marriage since marrying a wife in 1898 and one of the
crimes for which he was indicted and not tried was tha
rape upon a woman whom he induced to believe that he
her husband, thus causing her to spend a night with
A considerable part of his recent history was connected
this incident. He had met and made the acquaintance
medical man named Herbert Part, who was procee
abroad very soon after a marriage the details of which
not been published. Having obtained knowledge of
Herbert Part's private affairs and knowing that he w
be likely to remain abroad Cubbin personated him
being enabled thus to use a name that was on the Med
Register was protected in carrying on the illicit med
practice which seemed to exercise such an attrac
for him. As Herbert or Hubert Part, for he used
names, he went through a ceremony of marriage
a girl named Alice Ford and through her meeting
wife of the real Part was charged with bigamy. In
succeeding investigations his true character and a
cedents were revealed and it was found that before
ceremony with Alice Ford he had been married
to Ellen Mary Part but to another lady. The ease
which medical men can be personated should make t
cautious in dealing with plausible strangers claiming to
members of the same profession. The story of the wife w
even after a married life of only a few days' duration a
parting of three or four years, was deceived by a stra
into accepting him as her husband is an extraordinary
Such an occurrence renders many instances of mista
identity such as those connected with the late Tichb
claimant easier to understand and also shows that
identification of accused persons by witnesses at crim
trials may at times be entirely unfit to be relied upon.

The Liability of a Nursing Association.

An action of considerable interest to the medical
fession and to associations for the organisation and su
of nurses was tried by Mr. Justice Jelf and a spe
jury at the recent assizes held at Manchester.
plaintiff had undergone an operation for the removal
a kidney. Dr. G. J. Robertson of Oldham performe
with the assistance of two other medical men and
nurses supplied by the Oldham Nursing Association w
present. After the operation had been completed and a
the patient had been placed in her bed when recover
from the anæsthetic she cried out that her leg was be
burnt. A hot-water bottle was then removed by one of
nurses and Dr. Robertson afterwards dressed the leg wh
was very seriously injured, so that the patient was at
time in a critical condition. Dr. Robertson spoke to
nurses as to what had taken place and they appear to h
met his observations with indignant denial and the re
that the blame was with him. In consequence
what passed he immediately removed them and repla
them with other nurses from Manchester. Upon the issu
fact as to whether the hot-water bottle or bottles were u
upon the operating table or were placed in the bed a
the patient was in the hands of the nurses there was a di
conflict of evidence. Upon this issue the jury found t
the injury to the plaintiff was caused by the negligenc
the nurses. A further defence was raised that the relati
of master and servant or employer and employed did not e
between the Nursing Association and the nurses sent out b
so as to render the association liable for their negligence,
it was urged that the association was merely an agency for
benefit of the nurses, providing them with board and lodg
and making arrangements for their employment. On
other hand, correspondence with the association was put i
show that it contracted for the services of the nurses w
those who required their attendance upon patients, pay
them less than it received for their services and reserving
itself the right to recall them at any time. On this issue
jury found that the defendant association undertook to nu
the plaintiff through the agency of its nurses. A stay
execution pending an appeal upon this latter point was ask
for and refused, but no doubt the question of the liability
associations of this kind will be argued again before long
the Court of Appeal. The medical men whose credit was
stake in this trial to which they were not parties are to
congratulated upon the result of it. The damages w
assessed at £300.

Inaccurately Worded Legacies.

Recourse was had recently to the Chancery Division
order to ascertain the meaning of a testatrix who had

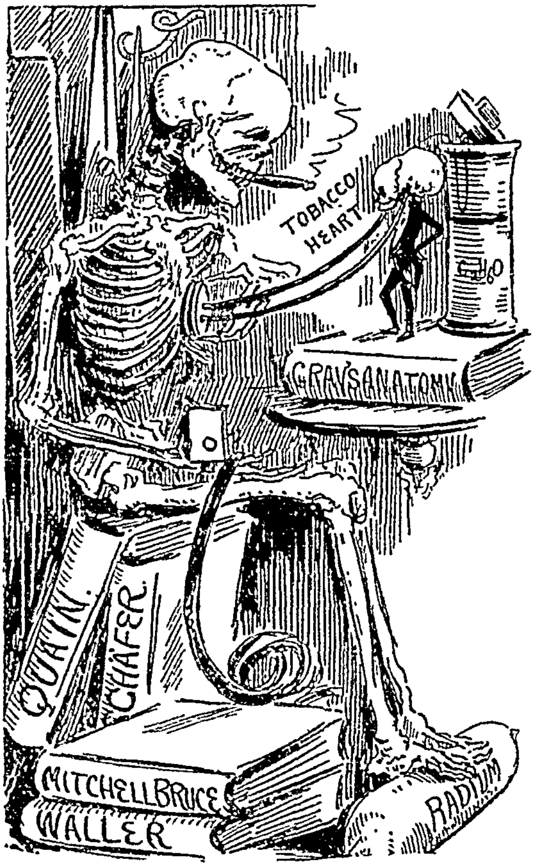
a legacy of £500 to the "Royal Home for Incurables, Streatham, S.W." She had subscribed during her lifetime to the "British Home and Hospital for Incurables" at Streatham and also to the "Royal Hospital for Incurables" at Putney. In her diary she had described the former as the British Home for Incurables and the latter as the Royal Home for Incurables and there was evidence as to her subscriptions of varying amounts to the two institutions which had to be considered in order to ascertain her probable wishes. The executors had paid the amount named to the Royal Hospital for Incurables at Putney, but Mr. Justice Kekewich was able to come to the conclusion from the facts laid before him that the British Home and Hospital for Incurables at Streatham was intended, in which, taking the indication of locality into consideration, he was pretty clearly right and the legacy will now go to that institution. It is a matter of regret that litigation should be necessary upon such a subject. In this particular case and in others the circumstances of necessary haste in which wills sometimes have to be made may account for errors and excuse them. Solicitors, however, who have any leisure to draft a will properly should take the opportunity to verify all names of charities submitted to them as objects of the testator's benevolence. With their accuracy in other matters we are not concerned. Hospitals and benevolent institutions of all kinds are properly described in the "Annual Charities Register and Digest" (published for the Charity Organisation Society by Messrs. Longmans and Co.) and in other accessible works of reference. Testators are known to be inaccurate, almost unaccountably so; they have at times described their relatives by wrong or by wrongly combined names, they have called their first cousins once removed second cousins and their step-children their children. It may sometimes be possible and desirable for the secretary to a charitable institution to whom a subscription is paid which is wrongly addressed, or accompanied by a letter describing the charity under a wrong name, to call attention to the error without giving offence.

A Dead Body as a Bequest for Anatomical Purposes.

There is no "property" or right of ownership in a human body and no man consequently can own the dead body of his relative or of any other person in such a way as to be able to sell it or to leave it by his will to anyone so as to make it that person's property. He cannot even so dispose of his own remains by any bargain or will made during his life but when he is dead it will be the duty of his executors to afford his body such burial as is suitable to his estate. There is an apparent exception to this created by the Anatomy Act (2 & 3 William IV., c. 75). The seventh section of this statute makes it lawful for an executor or any other person, not an undertaker, having lawful possession of a dead body to permit it to undergo anatomical examination unless either the deceased has in his lifetime desired otherwise or his surviving relatives object, and by the eighth section, "if any person, either in writing at any time during his life, or verbally in the presence of two or more witnesses during the illness whereof he died, shall direct that his body after death shall be examined anatomically, or shall nominate any party ...... to make such an examination ...... then the party having lawful possession of the dead body shall direct such examination to be made" unless a husband or wife or other near relative shall object. Recently at an inquest in London a document left by the deceased was read which expressed his desire that his body should be handed to the authorities at St. George's Hospital for dissection in the medical school and the coroner made the observation that the gift was invalid and that the deceased could not leave his body as he wished. The section quoted was apparently overlooked by the coroner and the man who said in his letter expressing his wish, "I have the right to dispose of my body," was right so far as the particular mode of disposition selected by him was concerned. There does not appear to be any recorded case where anyone to whom a body should have come for anatomical purposes under Section 8 ever sought to enforce that right against an unwilling executor, but the wording of the section appears to leave the executor no choice in the matter so long as the relatives do not object. The phraseology used would apparently include post-mortem examinations made for the purpose of elucidating the cause of death (but not ordered by a coroner) as well as the handing over of a body for dissection in a medical school.

LEEDS MEDICAL SCHOOL: A SMOKING CONCERT.

A SMOKING concert was recently given by the Leeds Medical School under the chairmanship of Mr. W. H. Brown when a programme of 17 items, all songs but four, was successfully carried out. The bill of the evening was very happily drawn by Mr. Fred. Reynolds, as may be seen by our reproduction of the principal figure upon it.



VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7950 births and 5092 deaths were registered during the week ending Nov. 28th. The annual rate of mortality in these towns, which had been 16·2, 17 9, and 17·4 per 1000 in the three preceding weeks, increased again last week to 17·6 per 1000. In London the death-rate was 17·4 per 1000, while in the 75 other large towns it averaged 17·7 per 1000. The lowest death-rates in these towns last week were 8·0 in Hornsey, 8·1 in Wallasey, 8·7 in Hastings, 9·0 in Stockton-on-Tees, 9 3 in Walthamstow, 9·7 in Leyton, 10·3 in Croydon, and 10 6 in Smethwick; the highest rates were 23·0 in Coventry, 23·2 in Bootle, 23·6 in Warrington, 23·7 in Preston, 24 7 in York, 25·1 in Swansea, 26·2 in Burnley, and 29 6 in Sunderland. The 5092 deaths in these towns last week included 430 which were referred to the principal infectious diseases, against 419, 432, and 436 in the three preceding weeks; of these 430 deaths, 114 resulted from measles, 99 from diphtheria, 92 from whooping-cough, 49 from diphtheria, 42 from "fever" (principally enteric), 30 from scarlet fever, and four from small-pox. No death from any of these diseases was registered last week in Croydon, Hornsey, Hastings, Bournemouth, Norwich, Devonport, Handsworth, Smethwick, Grimsby, Wallasey, Huddersfield, Middlesbrough. Stockton-on Tees, or Tynemouth; while the highest death-rates from the principal infectious diseases occurred in Willesden, Walsall, Bootle, Warrington, Bury, Preston, York, Sunderland, and Rhondda The greatest proportional mortality from measles occurred in Willesden, Ipswich, West Bromwich, Warrington, Preston, York, and Sunderland, from whooping cough in Walsall, Bootle, Warrington, and York, and from diarrhœa in Preston and York The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns Of the four fatal cases of small pox registered in these eight towns last week one belonged to London, one to Coventry, one to Newcastle on Tyne, and one to Tynemouth The number of small pox patients under treatment in the Metropolitan Asylums hospitals, which had been 43, 51, and 47 at the end of the three preceding weeks, had further declined to 40 at the end of last week, five new cases were admitted during the week, against five, 16, and five in the three preceding weeks There were 1770 scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, Nov 28th against 1854, 1824, and 1833 on the three preceding Saturdays, 157 new cases were admitted during last week against 224 185, and 191 in the three preceding weeks The deaths referred to pneumonia and diseases of the respiratory system in London, which had been 271, 339, and 325 in the three preceding weeks, rose again last week to 399 and were 18 above the number in the corresponding period of last year The causes of 57, or 1 1 per cent, of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham Bristol, Leicester, Leeds, Hull, Newcastle on-Tyne, and in 44 other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Grimsby, Nottingham, Liverpool, St Helens, Preston, Barrow in Furness, Sheffield, and Gateshead

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 15 8, 17 4, and 17 4 per 1000 in the three preceding weeks, further rose to 18 7 per 1000 during the week ending Nov. 28th and was 1 1 per 1000 in excess of the mean rate during the same period in the 76 large English towns Among these Scotch towns the [illegible] Perth and 11 6 in Aberdeen, [illegible] n Paisley The 611 deaths [illegible] were referred to diarrhœa 17 to measles, nine to whooping cough, five to diphtheria, four to "fever," three to small pox, and two to scarlet fever In all, 62 deaths resulted from these principal infectious diseases last week, against 53, 49, and 61 in the three preceding weeks These 62 deaths were equal to an annual rate of 1 9 per 1000, which was 0 4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 20 in each of the two preceding weeks, increased last week to 22 of which 12 occurred in Glasgow, five in Edinburgh, two in Aberdeen, and two in Paisley The deaths from measles, which had been 19 10, and 13 in the three preceding weeks, rose again to 17 last week and were all registered in Glasgow The fatal cases of whooping cough which had been four and seven in the two preceding weeks, further rose last week to nine of which seven occurred in Glasgow The deaths from diphtheria, which had been four and seven in the two preceding weeks, declined again to five last week and included two in Glasgow The fatal cases of fever," which had been ten and six in the two preceding weeks, further declined last week to four, of which three were recorded in Glasgow, where the three deaths from small pox also occurred The deaths referred to diseases of the respiratory organs in these towns, which had been 107, 129, and 136 in the three preceding weeks, further rose last week to 148, and were 13 in excess of the number in the corresponding period of last year The causes of 14 or more than 2 per cent, of the deaths registered in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin which had been 21 7, 20 9 and 24 5 per 1000 in the three preceding weeks further rose *to 24 8 per 1000 during the week ending Nov 28th During the past four weeks the death rate has averaged 23 0 per* 1000 the rates during the same period being 16 7 in London and 17 0 in Edinburgh The 180 deaths of persons belonging to Dublin registered during the week under notice were slightly in excess of the number in the preceding week and included 11 which were referred to the principal infectious diseases, against two, seven, and nine in the three preceding weeks, of these, four resulted from "fever," three from whooping cough, three from diarrhœa, and one from diphtheria, but not any from small pox, measles, or scarlet fever These 11 deaths were equal to an annual rate of 1 5 per 1000, the death rates last week from the principal infectious diseases being 1 3 in London and 1 1 in Edinburgh The fatal cases of "fever," which had been one, three and one in the three preceding weeks, rose last week to four The deaths from whooping cough, which had been three and two in the two preceding weeks, rose again to three last week The three fatal cases of diarrhœa showed a slight decline from the number in the preceding week The 180 deaths in Dublin last week included 48 of children under one year of age and 47 of persons aged 60 years and upwards, the deaths of infants were 17 in excess of the number in the preceding week, while those of elderly persons showed a slight decline One death from violence and four inquest cases were registered, and 54, or nearly one third, of the deaths occurred in public institutions The causes *of* ten *or nearly* 6 per cent., *of the deaths* registered in Dublin last week were not certified

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Christopher Pearson has been promoted to the rank of Deputy Inspector General of Hospitals and Fleets in His Majesty s Fleet (dated Oct. 10th, 1903)

The undermentioned gentlemen have been appointed Surgeons in His Majesty's Fleet, viz —Walter Perceval Yetts, Norman Sinclair Meiklejohn, Thomas Dixon Liddle, William Perceval Hingston, Guy Leslie Buckeridge, Arthur Henry Sims Richardson, Henry Woods, George Herbert Stephens Milln, Charles James Boucher, Reginald Hugh St Bernard Ellis Hughes, Frederick Morton Vincent Smith, George Deleval Walsh, David Haddon Vickery, Palmer Devoy Ramsay, Walter Graham Moore Anderson, Arthur Robertson Davidson, Edward Bryan Kenny, James Ernest Johnston, James Campbell Bringan, Francis Jollie Gowans, John Shipsey, Lionel Coldbeck Esmonde Murphy, Frederick Cock, Evelyn Richard Townsend, Arthur Dillon Croker Cummins, Charles Murray Woods, Arthur Reginald Schofield, Thomas Walter Jeffery, Edward Postle Gwyn Causton, and Bertram Raleigh Bickford (dated Nov 23rd, 1903)

The following appointments are notified —Fleet Surgeon E B Townsend to the *Monmouth* Staff Surgeons J D Hughes to the *Pioneer* and W R M Young to the *Venus* Surgeons J Macdonald to the *Hibernia* for the *Maine* and A D Spalding to the *Jackal*

ARMY MEDICAL STAFF.

Colonel J D Edge, C B Royal Army Medical Corps, to be Surgeon General, vice G J H Evatt, C B, retired (dated Nov 11th, 1903)

ARMY MEDICAL SERVICE

Surgeon General Thomas O Farrell is placed on retired pay (dated Nov 20th, 1903)

ROYAL ARMY MEDICAL CORPS

Lieutenant Colonel J J Morris to be Colonel, vice J. D Edge (dated Nov 11th 1903) Lieutenant Colonel H Grier is placed on temporary half pay on account of ill health (dated Nov 20th, 1903)

VOLUNTEER CORPS

Rifle 1st Volunteer Battalion the East Lancashire Regiment Surgeon Lieutenant A Foster resigns his commission (dated Nov 28th 1903) 1st Bucks Surgeon Captain J Shaw resigns his commission (dated Nov 28th, 1903) 1st Nottinghamshire (Robin Hood) Captain R P Shearer resigns his commission and is appointed Surgeon-Lieutenant (dated Nov 28th, 1903) 1st Tower Hamlets Surgeon-Lieutenant J F F Parr to be Surgeon Captain (dated Nov 28 h, 1903)

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

The Edinburgh Company · Major D Hepburn resigns his commission with permission to retain his rank and to wear the prescribed uniform on retirement (dated Nov. 28th, 1903). The Glasgow Companies: Captain J. G. Graham resigns his commission (dated Nov. 28th, 1903).

DEATHS IN THE SERVICES.

Surgeon General Alfred James Dale, I.M S. (retired), on Nov. 24th at his residence in Rosary Gardens, South Kensington, aged 73 years. He entered the service in 1853, was promoted surgeon in 1864, surgeon-major in 1873, brigade-surgeon in 1879, deputy surgeon-general in 1882, and retired with the rank of surgeon-general in 1886. He served in the Afghan War in 1879 with the Kuram Valley Field Force (medal).

Surgeon-Major Hamilton De Tatham, I.M.S. (retired), on Nov. 25th, in his sixty-first year. He entered the service in 1867 and was promoted surgeon-major in 1879. He served in the Abyssinian War in 1867–68 (medal).

Correspondence.

"Audi alteram partem."

BAYLISS *v.* COLERIDGE.

To the Editors of THE LANCET.

SIRS,—May we ask you to be good enough to give publicity in your columns to the following undertaking and apology which we have obtained from the publisher of "The Shambles of Science," a work intimately associated with the above action. We may state that the terms of Mr. Bell's undertaking have been complied with.

To Dr. W. M. Bayliss, "St. Cuthberts," West Heath-road, Hampstead, and to Messrs. Hempson, 35, King-street, Cheapside, E O. (his Solicitors).

I, the undersigned Ernest Bell of 6, York-street, Covent Garden, London, W.C., the printer and publisher of a book entitled "The Shambles of Science," the authors of which are Lizzy Lind Af Hageby and Leisa K. Schartau, and which book contains therein certain matter libellous upon Dr. Bayliss hereby acknowledge that I have given instructions for the withdrawal from circulation of all copies of such book and hereby undertake that no further copies of such book shall be printed or published by me, that the circulation of such book shall cease, and that all copies in stock and withdrawn from circulation shall be handed over to Messrs. Hempson, Dr. Bayliss's solicitors, and I hereby express to Dr. Bayliss my sincere regret for having printed and published the book in question.

Dated, this 25th day of November, 1903.
Witness, HENRY RAYMENT. ERNEST BELL.

In the interests of truth and of science it is desirable that it should be publicly known that the circulation of the book has been suppressed.

We are, Sirs, yours obediently,
HEMPSON AND CO.,
Solicitors for Dr. W M. Bayliss.
35, King-street, Cheapside, London, E.C., Nov. 28th, 1903.

RECURRENT OVARIAN CYSTOMA AND ABERRANT ACCESSORY OVARIAN STRUCTURES.

To the Editors of THE LANCET.

SIRS,—Mr. Roger Williams shows in THE LANCET of Nov. 28th (p. 1530) that "of 138 ovarian tumours from the Kelly clinic submitted to microscopical examination at the Johns Hopkins Hospital 11, or 8 per cent, were malignant." Greig Smith[1] quoted Shroeder as having 16·6 per cent. of malignant cases in 600 ovarian tumours and he also quoted Leopold as finding that 22·4 per cent. were malignant in 126 cases. Mr. Williams contrasts the 8 per cent, which he takes as the proportion of malignant disease in these cases, with "the great frequency of its occurrence after ovariotomy, which in Spencer Wells's large experience amounted to no less than 36 per cent." He obtains the 36 per cent. from a table of 1000 cases of ovariotomy[2] and a summary of the results[3] in Sir Spencer Wells's book on ovarian and uterine tumours. Of the 1000 cases of completed ovariotomy, 117 were reported as having died after recovering from the operation, but the cause of death was known only in 88, and in 32 of these cases death was due to cancer. This shows a malignancy of about 36 per cent. *in the 88 cases.* It does not seem to me, however, that it may be logically argued from this that the occurrence of malignant disease after ovariotomy "amounted to no less than 36 per cent." In addition to the 32 patients who died of cancer after convalescence was complete there were four who died with cancer immediately after their operations. Thus there is evidence of the occurrence of 36 cases of malignant disease in the 1000 and the figures seem to me only to warrant the assertion that at the time of publication malignant disease had developed in 36 cases or 3·6 per cent of the whole. The comparison made by Mr. Williams is appropriate only if it can be shown that the incidence of malignancy in the 88 cases constitutes a fair sample of the results to be expected in the cases still alive at the date of publication. If this is so, malignant disease would develop in about 276 of the 768 cases which were not immediately fatal from the operations—a truly appalling result.

There are, however, reasons, which seem to me conclusive, indicating that the patients surviving a few years would not be so liable to malignant disease as those dying early. The 1000 cases were operated on between 1858 and 1880 and were published in 1882. Of the 36 patients who had or developed cancer four (Nos. 747, 155, 236, and 882) died on the sixth, twelfth, thirteenth, and fourteenth days respectively after their operations; one died after six weeks (No 111); six more died within six months (Nos. 61, 63, 331, 433, 764, and 890); 13 more died within two years (Nos 3, 151, 330, 397, 519, 545, 557, 605 656, 712, 762 802, and 977); another three died within three years (*Nos. 696, 810, and 904*); two died after about three years (Nos. 774 and 832); three in about four years (Nos. 127, 494, and 691); one in five years (No. 736); and one in seven years (No. 2). In two cases (Nos. 831 and 847) the duration of life after ovariotomy is not stated, but as both patients were operated on in 1877 they must have died within six years. Thus 27 of the 36 patients that had cancer died within three years of their operations.

I think it will hardly be gainsaid that the four patients dying with cancer within a fortnight of their operations had malignant disease when they were operated on. Moreover, it is incontrovertible that in many cases when an ovarian tumour is removed and examined under the microscope conclusive evidence of the presence of cancer may be found. The patients may become quite well for a time but the disease, so far as my experience goes, always recurs and usually this is evident within three years. Hence, when I see that so many of Spencer Wells's cases developed malignant disease within three years of being operated on the conclusion seems to me unavoidable that in most of them, if not in all, the disease removed was malignant. The 3·2 per cent. in which a recurrence (as I believe it to be in most of the cases) took place and the 0·4 per cent. of cases dying from the operation, with cancer, make 3·6 per cent, a figure very much below the 8 per cent. which Mr. Williams quoted as the percentage of malignancy in ovarian tumours. A larger number of cases of malignant disease was therefore to be expected and there is no doubt that a later investigation would have revealed more by allowing other cases time to develop. But the table only included completed ovariotomies and therefore many malignant cases would not be in it. As three-fourths of the deaths from malignant disease occurred within three years of removal of the ovaries, and none after seven years, it is obvious that the patients who lived beyond three years would show a much smaller proportion of deaths from malignant disease, so that when all were dead the percentage of 36 would be very materially reduced. In THE LANCET of Nov. *14th*, p. 1394, Mr. Williams wrote that there is "an extraordinary frequency of malignant disease after removal of both ovaries." This is not supported by Spencer Wells's table, for only six of the patients dying from malignant disease had both ovaries removed. This gives 0·6 per cent. which cannot be described as "extraordinary frequency."

I am, Sirs, yours faithfully,
JOHN D. MALCOLM.
Portman-street, Nov. 30th, 1903.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—In view of the communication of Dr. R. D Rudolf to THE LANCET of Nov. 21st, p. 1461, and a further communication from Dr. H. Campbell in THE LANCET of Nov. 28th, p. 1531, perhaps you will kindly allow me to add a few words to my last letter There seems to be a misconception on the part of Dr Harry Campbell, otherwise he would not deem it necessary to insist on such an elementary physiological fact as that the inspiratory muscles augmented pulmonary suction, or, in other words, the negative intrapleural pressure Of course they do, but such augmentation is produced by these muscles acting as an opposing force to the resistance offered by the pulmonary tension (or suction) or, to use my former expression, they are "directed against this resistance Now this is quite a different condition of affairs from that which obtains at birth (or say in very extensive emphysema) At birth there is no negative pressure in the pleural cavities, no pulmonary tension acting [illegible] tory muscles , consequently in [illegible] ld s lung the forces inside and [illegible] the same direction, whereas when pulmonary elasticity is established these forces are acting against each other Surely, therefore, my contention is correct that these conditions are "not parallel" With regard to the other points in his letter, I have stated several times the limits of passive recoil and if Dr Campbell now admits this factor to be alone competent to produce a certain degree of thoracic expansion it is a pity that he should have made use of the expression "any expansion" As to the effect of the lung traction on the auricles I am not aware that physiologists have ever doubted that for which Dr Campbell contends

[1] Abdominal Surgery, third edition, p. 156

Spencer Wells: Ovarian and Uterine Tumours, 1882, pp. 342-393.

[3] Loc. cit. p. 475.

Coming to the possible extension of the lung borders in connexion with the production of the lung reflex there is a consideration introduced by Dr Campbell which can be disposed of without much difficulty He states that "by means of a complete inspiration the borders of the lung are made to travel to the uttermost confines of the pleura' and *that a more extensive downward movement of the lungs than this* must be "a physical impossibility" Such is by no means the case The pleura does not descend as far in the thorax as the diaphragmatic attachments and after the pleural cavity is fully filled by the lungs there remains an interval into which the lungs can be stretched As this is a fact of much importance and possibly but little known I may here quote Cunningham, than whom there is no greater authority "The diaphragmatic pleura covers the portion of the upper surface of the diaphragm which lies to the outer side of the base of the pericardium, but it does not dip down to the bottom of the narrow interval between the thoracic wall and the diaphragm In other words, a strip of the upper surface of the diaphragm adjoining its costal attachment is left uncovered"[1]

Dr Rudolf has made some very interesting observations and like him I have also found certain discrepancies in the results obtained, but I am not to be held as endorsing every phenomenon described by Abrams not because I have failed to obtain them, but because I have not had sufficient experience to warrant my giving an opinion. I have certainly obtained many of his results and for the rest I shall believe what he says owing to his already proved reputation as an observer In regard to a great descent of the lung by means of the ether spray Abrams affirms that he can produce this ' dependent upon certain conditions," and until these conditions are fulfilled any results obtained are inconclusive It would have been more satisfactory seeing Dr Rudolf attempted to elicit the reflex on subjects who had already practised deep inspirations if he had made control experiments so as to check any possible disturbing effects of these His observation of a rhythmical contraction and dilatation of the lungs is of high interest both intrinsically and in connexion with the lung reflex phenomenon and I can only endorse his hope that these matters will receive the full investigation which they deserve

I am Sirs, yours faithfully,
A G AULD

Henrietta street W Nov 28th 1903

THE ACTION OF MEDICINAL AND OTHER REMEDIES IN CARDIAC FAILURE

To the Editors of THE LANCET

SIRS,—At the very interesting and instructive discussion that followed Sir R Douglas Powell's paper on this subject at the meeting of the Medical Society of London on Nov 23rd, time did not allow many Fellows to speak who would otherwise have done so Perhaps you will allow me the hospitality of your journal for one or two remarks The use of oxygen in heart failure, both from disease of the organ itself and in dilatation in the course of pneumonia, was strongly advocated by the reader of the paper and subsequent speakers It was, however, pointed out that the extreme coldness of the gas when inhaled direct from the cylinder might do some harm, especially in pneumonia I get over this difficulty by connecting the cylinder with a large Woulfe's bottle half filled with hot water by which means the gas is not only warmed but also moistened An additional advantage of this arrangement is that one can see at a glance the rate in which the gas is issuing —I am, Sirs, yours faithfully,

CHAS W CHAPMAN

Weymouth street, W , Nov 30th, 1903

THE NOMENCLATURE OF TRYPANOSOMES

To the Editors of THE LANCET.

SIRS,—At a time when our knowledge of trypanosomes is extending rapidly and when within a brief space of time several new species have already been discovered it seems opportune to call attention to the law which governs the naming of a genus and its species—a law accepted without any reservations by all scientific men Briefly it is the "law of priority" which establishes once and for all the generic and specific names Thus, if an observer describing an organism for the first time does so in such a way as to make his description recognisable to subsequent observers and if he at the same time proposes to call the organism *A a*, then that name holds good *absolutely* and *immutably always* and it is not possible for a subsequent observer to call it *A b*, and even if it were shown later that the organism does not belong to the genus *A* but to the genus *B*, *a* (the specific name) still holds good as *B a*

I desire to point out how in the naming of trypanosomes this law has lately been broken Leaving totally aside any question of priority of discovery, for it has not the least bearing on this matter, it was Dutton who first described a trypanosome in man and also proposed for it the name trypanosoma Gambiense If Dutton had not taken the remotest part in the discovery this name absolutely has priority and consequently trypanosoma hominis (Manson) and trypanosoma Nepveu (Sambon) must disappear Similarly Castellani describing the trypanosome at present associated with sleeping sickness, proposed for it the name trypanosoma Ugandens [illegible] tellani (Kruse) subsequently [illegible] Should eventually trypanoso [illegible] e shown to be the same as [illegible] the former must also disa [illegible] (Dutton) must therefore [illegible] the trypanosome of human trypanosomiasis and trypanosoma Ugandense (Castellani) for the present, at any rate, of that associated with sleeping sickness

I am, Sirs yours faithfully,

THE TREATMENT OF LUPUS

To the Editors of THE LANCET

SIRS,—I was glad to note Dr R Prosser White's comment upon my article the Successful Treatment of a Few Cases of Lupus, which appeared in THE LANCET of Nov 14th, p 1353 I was also glad to note the success that Dr White has had in excision of similar cases I feel convinced that excision combined with other treatment is most efficient where the disease is not far advanced being more speedy in its effect and certainly less disfiguring in result than many methods of treatment. Dr White inquires my reason for injecting arsenic From experience I have found that this assists very materially the healing process after excision Whether it is due to the alterative action of arsenic on the system or to its tonic action on the skin I cannot say, but it is certain that cases do better with than without it Even in cases of eczema psoriasis &c , arsenic administered subdermically is attended with far superior results than when given by the mouth The tuberculin injections after excision I consider of the greatest importance as a prophylactic measure and from the fact that we can never be certain, however well excision has been performed, that all the diseased tissue has been completely removed. I have always found a reaction from the tuberculin injections after apparent thorough extirpation of very small patches of lupus, showing, I think, definitely, some remaining tuberculous material somewhere.

I am, Sirs, yours faithfully,
Newport, Mon., Nov. 28th, 1903. C. STANSER BOWKER.

THE BEHAVIOUR OF CANCER IN NERVE AREAS.

To the Editors of THE LANCET.

SIRS,—May I be allowed to add two remarks which your reporter omitted in epitomising my communication to the meeting of the Pathological Society of London held on Nov. 17th. I was speaking on the behaviour of carcinoma within nerve or trophic areas. I showed rodent ulcers corresponding to the areas of distribution of certain muscles Your reporter omitted to say that they were the cutaneous muscles of the face. The addition is an important one because it is as yet unknown what is the exact nervous relationship between those cutaneous muscles and the skin of which they are component parts.

Neither does the epitome include that I showed, or attempted to show, that muscular, fascial, vascular, and lymphatic limitations were not the predominent factors of distribution of these ulcers, but their spread and areas of occupation were probably mainly influenced by a nerve or trophic agency. I am, Sirs, yours faithfully,
Harley-street, W., Nov. 25th, 1903. G. LENTHAL CHEATLE.

MEDICAL FACULTY OF THE UNIVERSITY OF LIVERPOOL.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a mistake in the return made by me of the winter entry of medical students at the University of Liverpool and published in THE LANCET of Oct. 31st (p. 1242). The number 111 in the first column represents the total number of students now in the school who are taking the full medical curriculum. The number of students entering for the first time and taking the full medical course is 23, as against 24 last year.

I am, Sirs, yours faithfully,
B. MOORE,
Dec. 1st, 1903. Dean of Medical Faculty.

SHIPS' SURGEONS AND FEES FROM PASSENGERS.

To the Editors of THE LANCET.

SIRS,—In a series of articles on "Life on a Liner" published recently in *Lloyd's Weekly* I notice that "The Ship's Doctor" refers to the subject of fees from passengers for medical attendance. His remarks are as follows :—

> Many travellers are in doubt as to the position of the ship's doctor in regard to his remuneration from passengers for services rendered. The Merchant Shipping Act enacts that "every foreign-going ship having 100 persons on board, or upwards, shall carry on board as part of her complement a duly qualified medical practitioner" Furthermore, an emigrant ship (i.e., a foreign-going ship which carries 50 or more steerage passengers) must have a medical man irrespective of the number of the crew or of the other passengers carried. The salary of the doctor on board is commensurate with these duties to his ship. To any passengers who are suffering from ordinary forms of sea-sickness and its concomitant evils or who receive injuries which are in any way due to the ship—for example, as from a fall produced by the ship's rolling—the doctor's services are free. For any sickness contracted before sailing or during a voyage which is not connected with the above-named conditions he is entitled to a remuneration at the same rate as he would receive on shore. Obviously it would be as unfair to expect that his services to passengers should be rendered gratis as it would be for any visitor in a hotel or traveller on the railway to expect to have medical attendance free in any illness for which the hotel or railway authorities could not be held responsible.

The case has here been put clearly and concisely. After seven years' experience in first-class ocean-going steamers I should like to supplement these remarks with a few of my own observations. Ships' surgeons are of two kinds: 1. Those who at the end of a college curriculum, for health or the sake of pleasure and to see the world, take a voyage or two as surgeon thereby saving travelling expenses. Such men, I take it, are not particularly interested in the emoluments attached to any position which they do not intend to hold for any time. Not a few, I fear, have earned a reputation for intemperate habits, hence the suspicion still lurks in the minds of too many that because a man is a ship's surgeon therefore he is not much good. 2. Those who for various reasons elect to make the sea life a permanency. That the post of ship's surgeon in first-class passenger lines is difficult to obtain and that attainments, professional and social, of a high order are required of those who hold them are known best to those concerned. "The Ship's Doctor," in quoting from the Merchant Shipping Act, demonstrates clearly that in large passenger ships the surgeon's first obligations are to his ship and the crew for whose benefit he is employed by the company. For this he receives a "wage" varying from £6 to a maximum of £10 per month. Were this to be the only remuneration obtainable at sea it is reasonable to suppose that no experienced or well-qualified surgeon could stay any time on a ship.

As regards passengers in relation to the surgeon I think the following groups will include all: (1) the passenger who takes the initiative by remunerating the surgeon, perhaps handsomely, for any services rendered; (2) the passenger who, at the end of a consultation or attendance, will at once ask for his bill and pay it if reasonable; (3) the passenger who, travelling perhaps for the first time, really does not know whether to approach the surgeon or to wait for a bill being sent in or what he ought to do but is pleased to be enlightened on the matter; (4) the passenger who, either wilfully or through ignorance, clings to the old-time notion that the surgeon is there solely for the benefit of passengers; and (5) the passenger who never intends to pay the surgeon any more than he intends to tip the steward or the stewardess for any services rendered.

Of these groups the last two are obviously unsatisfactory to deal with. The difficulty is increased by the fact that seldom is a ship's surgeon allowed by his company to send in a regular bill for attendance as he could do on shore. Why he should not do so and thereby make it a matter of ordinary business instead of sentiment seems difficult to imagine. I presume that the particulars of the bill would be open to analysis both by the patient and by the company if referred to them; therefore any overcharge by the ship's surgeon who did not know his business could be remedied or repudiated. I have met at least three managers who have considered it right and proper that the surgeon should send in a bill for attendance. Of these one I remember who summoned me to answer the charge made by a passenger that I had presented him with a bill for five guineas for three weeks' attendance while suffering from syphilitic ulceration of the mouth. "Doctor," said the manager, "I am surprised at your folly for trying to convert our ship into a hospital for the treatment of venereal disease. You ought to have charged that man 25 instead of five guineas." In "Presbrey's Information Guide for Transatlantic Travellers," published and circulated on all steamers by the Frank Presbrey Company, New York, U.S.A., the following lines appear: "It is an erroneous impression that the ship's physician is provided solely for the accommodation of passengers. Maritime laws require steamship companies to employ physicians on all vessels carrying large crews. Every transatlantic steamer carries a competent physician and surgeon whose services are obtainable by passengers at corresponding rates of remuneration to those paid on shore." This recommendation from such a reputable source is valuable, but, of course, is not "official." Even if companies were to allow their surgeons to send in a bill I know from experience and for reasons already stated that in the majority of cases there would be no occasion to render it. In order to deal with the class of passengers who do not intend to pay the surgeon at all, the remedy I would suggest is *that the bill be sent in not in the surgeon's, but in the company's, name.* This would bring home the obligation to the passenger and the company could deal thereafter with the surgeon on the matter as they considered proper. "The Ship's Doctor" is wise in recognising that no remuneration should be suggested in the case of an injury to a passenger being due to any fault of the ship or carelessness, perhaps, of the crew.

One other point. Passengers often call at, or send to, the surgery for pills, powders, &c., where no attendance or consultation is asked or even necessary. I have known ships' surgeons foolish enough to make a charge for these. This is radically wrong, inasmuch as the drugs being provided by the company, are not theirs to sell. To charge for *professional skilled advice* is quite another matter. The fact that ships' surgeons, isolated as they are at sea, have little chance even of meeting in consultation, urges me to lay this matter before those whom it may concern through the medium of your valuable columns in the hope that they may see that nothing I have stated is either untrue or unreasonable. Perhaps, also, thereby misunderstandings which have hitherto existed may be removed.

I am, Sirs, yours faithfully,

Nov. 27th, 1903. ANOTHER SHIP'S DOCTOR.

THE FUTURE OF ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I am glad to find that Mr. Andrew Motion has not the hardihood to repeat his statement that "the views of the staff have never reached the governors." My object in writing has been attained and I thank you for the opportunity you have afforded me of proving beyond the possibility of contradiction that no one can truthfully say that the staff did not inform e [illegible] fully of their opinions more th [illegible] add that I did not expect Mr. [illegible] isfactory answers to my questions as to what action he has taken in the past, neither do I regret his reticence. My questions have quite satisfactorily answered themselves, for Mr. Motion's silence as to what he did is more eloquent than many words.—I am, Sirs, yours faithfully,

Nov. 30th, 1903. A ST. BARTHOLOMEW'S MAN.

THE ASSURANCE OF UNDER-AVERAGE LIVES.

To the Editors of THE LANCET.

SIRS,—Should a medical officer recommend for acceptance at ordinary rate on a "limited payments" scale a life chargeable with an extra premium on the "whole of life" scale? It seems to me that the practice where it exists must be due to misapprehensions not altogether unnatural as to the relationship of one scale of premium to another and the relative position of a life office with reference to the risks on each scale. Yet it concerns both the medical profession and the life offices that on points common to both clear *general* ideas should be held, whatever may be considered reasonable in isolated and exceptional cases. I therefore venture to ask space in your columns for a discussion of the question I have put.

To take an example. At the age of 35 years the average "with profits" premium payable during life is about £2 16*s.* per cent. for a first-class life, while the corresponding rate limited to 20 annual payments for the same benefit—an assurance of £100 payable at death—is about £3 16*s.* Now, on the "whole of life" scale an under-average life is generally admitted as at an advanced age, or, what is practically the same thing, at an addition to the normal premium of it may be from 5*s.* to 20*s.* per cent. of the sum assured. But suppose such a life were willing to pay on the 20 years scale. It might at first sight seem that the higher premium justified the office in dispensing with extra altogether or at least in accepting at a modified addition. I venture to think otherwise and would offer the following considerations. Both premiums are based on the mortality experience of first-class lives. The difference of 20*s.* between them is the discounted equivalent of the life scale premiums after 20 years. To set it in whole or in part against extra risk is to make it do double duty, for which it is inadequate. It places the under-average life on the same footing as a first-class life, adopting the same scale, and is thus unfair to the latter. If the excess over the life scale rate were adequate for both purposes—for commutation and to meet extra risk—1 [illegible] on the [illegible] rate, [illegible] passes current thereafter as first-class. In a subsequent proposal to another office he may be able to conceal the full truth as to the previous acceptance.

These appear the main objections to the practice. There are other considerations against it but I pass these to answer one or two points that might be urged in its favour. It might be said that if the life survives at least long enough to complete the 20 payments the office is safe. But that does not follow. The office has not merely to receive premiums but to pay the claim and if the claim is accelerated—if, in other words, the normal "expectation of life" on which the premium is based does not hold good for the class of lives in question—the office must lose no matter how many premiums have been received. Again, it might be said, if the life should fail before the premium has ceased then the office will generally have received more than the life-scale rate with a substantial addition and thus be actually better off than if the latter had been charged. No doubt; still the fact remains that the addition had quite another purpose to serve, as already explained. An office must balance losses with gains, and where are the gains in the case of those lives of the same class that survive long enough to be free of premiums and yet by hypothesis fall short of the normal expectation? If all the under-average lives are to fail within the 20 payments period the business cannot be good for the office. And to say that in the case of those that do fail the loss has been minimised is to forget that on life scale with a suitable extra the office would be recouped out of the premiums of those who would survive the 20 years period.

What, then, should be the "limited payments" extra corresponding to a given extra on "whole life" scale? Any investigations of my own point to an *increased* extra, the increase over the "whole life" extra depending mainly on the scale selected and partly upon the *incidence*—whether immediate or deferred, increasing or decreasing—of the extra risk in the particular case. This may read like a counsel of actuarial perfection; nevertheless, I imagine it is one which most actuaries would concur in. I am of course aware that purely actuarial considerations do not alone affect this more than other assurance questions. No one, again, could be more sensible than I am of the services of medical science to life assurance. To those services the results of the recent official mortality investigation bear striking testimony in the light mortality disclosed. But the new tables are being adopted as the basis for the future and just on that account it is important to maintain the same high standard of selection as has hitherto been the rule.

I am, Sirs, yours faithfully,

Nov. 24th, 1903. ACTUARY.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Cooking in the British Army.—A Modified Form of the Liernur System of Drainage for Part of Bombay City.—The Plague Epidemic.—A Proposed Burial By-law for Calcutta.—The Great Improvement Scheme for Calcutta.—The Conservancy Question.

FURTHER steps are about to be taken with the object of banishing the native cook from the kitchens of British troops in India. Over 100 Warren's cooking ranges will be erected at various stations and 22 sergeant-cooks are to be appointed. A school of cookery is to be established at Poona at which non-commissioned officers will be trained to become sergeant-cooks and the soldier-cooks of batteries, squadrons, and companies will also be instructed there. In the plains during the hot weather the actual cooking will be done by natives supervised by British soldiers who will be responsible for cleanliness and the observance of sanitary conditions, but elsewhere and during the cool season the cooking will be done by soldiers. It is contemplated to introduce gradually Warren's cooking range at all stations where British troops are quartered. During field training the school students will be placed at the disposal of companies and a portion of the training will consist in taking a company away from barracks for several days during which individual cooking of rations will be the only manner of preparing food permitted. It is considered that every individual soldier should be trained to cook for himself exactly as he may have to do on service. Instruction will also be given upon the slaughter of animals and the baking of flour.

passed expressing the opinion that it is detrimental to the best interests of public health and the efficient carrying out of the laws relating thereto that medical officers of health should be appointed for limited periods and on a precarious tenure of office, and it is desirable that all medical officers of health should hold office upon the same terms as district Poor-law medical officers. It was also decided to request the council of the association to bring the question of the insecurity of tenure of office of medical officers of health before the divisions of the association.

Incorporated Society of Medical Officers of Health.

A dinner of the Midland branch will take place at the Grand Hotel, Birmingham, on Dec. 10th, at 7 P.M., when it is expected that Dr. Alfred Hill, late medical officer of health of Birmingham, and Dr. Joseph Groves, the president of the society, will be present as guests.

Housing of the Working Classes at Newport (Mon.).

The Newport (Mon.) town council placed itself in a very undignified position at a special meeting held on Nov. 24th, when the question of proceeding with a scheme for the erection of 66 workmen's houses which had received the sanction of the council on August 11th last[1] was again discussed. A proposal to defer the matter for 12 months was defeated, but a proposition to proceed at once with the scheme found 17 supporters and an equal number of opponents and the mayor declared that it was not carried. It is to be regretted that at the same meeting the housing committee was dissolved, for it has done most excellent work not only in preparing the scheme referred to but in the direction of causing uninhabitable houses to be closed or made fit for habitation.

Overcrowding in Bristol.

At the last meeting of the Bristol board of guardians during a discussion as to the adoption of four young girls of ages from eight to 15 years whose father was dead and whose mother was recently charged before the city justices with neglecting her children, a very lamentable condition was disclosed. It appears that the woman in question occupied two rooms and in one of them there slept, in addition to herself and the four girls, her son aged 20 years, her daughter aged 18 years, a child of three years, and a woman of bad character. According to the statements made by some of the guardians this is not an isolated instance and there would seem to be much more over crowding in one room tenements in Bristol than is generally supposed. One member of the board said that it would be a long time before he again subscribed to foreign missions, for it was apparent that there was a great deal to be done by home missions.

Nov. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Epidemic of Fever in Sligo.

WITHIN the past fortnight a serious outbreak of fever has appeared in the district surrounding the town of Sligo and so many patients have been admitted to the County Fever Hospital that it has become overcrowded. Dr. B. MacCarthy, medical inspector under the Local Government Board, attended a specially convened meeting of the hospital committee and his report which has just (Dec. 1st) appeared states that 48 cases of a malignant type of fever have already been admitted to the hospital and he feared that within a few days many more patients would be brought in. The report goes on to say that the hospital was absolutely without drainage and that the building was standing in a mass of sewage which was lapping its foundations. The medical men and nurses were in daily danger of losing their lives from the poisoned atmosphere which had now become so oppressive that the nurses found themselves unable to sleep at night The committee decided to have sewers constructed at once. Dr. MacCarthy also attended the meeting of the board of guardians and reported on the filthy condition in which he found many of the houses in the infected area and as to the necessity of the overplus fever cases being provided for in the workhouse hospital. The guardians decided to leave the arrangements to the inspector and to the medical officer of the workhouse.

Insanity in Ireland.

At a conference of representatives of Irish district asylum committees held in the Richmond Asylum, Dublin, on Nov. 25th, some most alarming statistics in reference to the great prevalence of insanity in Ireland were brought forward. The total number of registered lunatics in Ireland is 22,138, showing an increase for 1902 of 508, which is an advance of 47 upon the increase of the previous year and a higher average than for the past ten years. Not only is there an increase, but an increasing ratio of increase in the total number of the insane. Mr. E. D. O'Neill (Limerick) read the first paper in which he referred to the excessive use among the young of alcohol, tea, and cigarettes as factors in the causation of insanity. The terrible depression and the emigration of the young and the healthy were, he said, directly or indirectly responsible for a large portion of the insanity which existed in Ireland to-day. Dr. W. Graham (Belfast), in the second paper, pointed out that in 1844 the number of registered insane was 4714; in 40 years it was doubled, and in 1902 it was almost quadrupled—17,380. In 1882 the number of first admissions to asylums in Ireland was 2137, in 1901 the number had swelled to 2821. In 1882 there were under care per 100 000 of the population 269, in 1901 it had risen to 487. He regarded alcoholism not merely as a cause of insanity but as an effect as well. He pointed out that in Ireland the gentry and the middle classes (professional man, educated artisan, and farmer) are rapidly disappearing—that is, the country is being depleted of her best and strongest elements, retaining only the weak and the unfit. In the past 40 years 4 000 000 people have left the country. Dr. Thomas Drapes (Enniscorthy) read a communication pointing out that in Ireland the situation was little short of appalling for out of 4 500,000 people 25,000 were mentally incapable. He thought that unless drunkenness could be reduced as one of the chief causes of insanity there was little hope of any diminution. He recommended that children should be brought up in absolute ignorance of the taste of alcohol until they were of age and as long as possible afterwards. An interesting discussion followed.

The Ulster Hospital for Children and Women.

A bazaar in aid of the funds of the Ulster Hospital for Children and Women was opened by the Lord Lieutenant of Ireland in Belfast on Nov. 26th. The object of the effort is to wipe out a debt of £2000 and to form an endowment fund. Mr. H. C Craig, of Sydenham House, Belfast, has given £1000, thus practically liquidating half the debt. From the large number of people who are interested in the bazaar it is expected that a good sum of money will be raised.

Dec. 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Experimental Production of Aortic Atheroma by Repeated Injections of Adrenalin.

AT the meeting of the Biological Society which was held on Nov. 14th M. Josué read a paper upon the above subject. Atheroma is a chronic diseased condition of the economy which is generally attributed to the action of slow poisons; whether endogenous, as those due to defects of nutrition; or exogenous, such as tobacco, alcohol, and lead; or infective, such as the poison of typhoid fever. Some observers have added another factor—namely, arterial hypertension, whether local or diffused. Experiments with the injection of toxic substances have been made by Crocq, Boinet, and Remak, but these have not brought about any atheromatous lesions at a distance from the point of injection, while at that point they have never produced any calcareous plaques but only an occasional abscess. Intravenous injections, however, of adrenalin administered in small doses repeated for a long time have produced in the rabbit calcareous plaques but no actual lesion of the aorta. In rabbits which died after the first injection or even after five or six injections into the marginal vein of the ear no aortic lesion was produced. After eight injections of a very weak (*étendue*) solution spread over a period of five weeks the heart was found to be dilated and there was one calcareous plaque in the thoracic aorta and another lower down. In a rabbit which received 16 injections there were numerous plaques, while the heart was hypertrophied and dilated. Another rabbit which received 20 injections within a period of three months was found to have its aorta profoundly affected and the calcareous plaques were very numerous. Adrenalin, then, would appear to possess a specific action on the arteries and to be capable of bringing about a condition of atheroma, perhaps owing to its raising the arterial tension. If it be remembered that adrenalin is the secretion of the suprarenal capsules it is only reasonable to suppose that these organs may play an important part in the production of atheroma.

---

[1] THE LANCET, August 29th, p. 635.

The Revue de Déontologie and the Corporative Association of Medical Students.

A group of medical students have withdrawn from the general association of students and have founded an association of their own called the Corporative Association of Students in Medicine. This a sociation, the numbers of which are rapidly growing, proposes to publish a monthly journal and has founded the *Revue de Déontologie et d'Intérêts Professionels Médicaux*. The assistant editor of this journal is a student. It is to be feared that from the point of view of medical practice the editorial staff of this journal, being only students, are somewhat lacking in experience. The other medical journals are astonished to see this new review offering to give advice as regards medical practice, since the directors thereof are only at the threshold of their career.

Drinking Water for the Army.

In conformity with a resolution passed by the Senate after the question which was asked in the House relative to the sanitary state of the troops the Minister for War submitted to the Academy of Medicine a number of questions dealing with the supply of drinking water to the various garrisons. The Academy has just sent in its report which was drawn up by the medical inspector, M. Vallin, in the name of the commission. The commissioners were M. Proust, M. L. Collin, M. Brouardel, M. Ernest Besnier, M. Magnan, M. Motet, M. Chantemesse, M. Josias, M. H. Monod, M. Roux, and M. Vallin. The report states that the best measure of protection against water-borne diseases is to insure that all garrisons are supplied with pure spring water of which the source must be well protected. All chance of contamination of the water, both at its source of origin and during its course to the distributing centres, must be strictly guarded against, even if the contamination be only of a momentary nature. If these conditions are fulfilled no sterilisation of the water is necessary except as a temporary measure in the case of an accident. Filters need not be given up provided that they are kept in good order, but the report recommends a trial of sterilisation by means of heat, the sterilised water being carefully guarded against contamination occurring afterwards.

Different Letters of the Alphabet from the Point of View of Rapidity of Reading.

At the meeting of the Academy of Sciences held on Nov. 16th M. André Broca and M. Sulzer communicated a paper upon the above subject, following on some researches which they had carried out. They showed that the different letters of the alphabet are not all apprehended with the same quickness. For instance, the time taken to recognise an E is nearly one-third longer than that taken to recognise a T. They consider that the alphabet is badly designed from a physiological point of view. It should be composed of very simply designed letters such as T or L Rapidity of reading would thus be increased and cerebral fatigue would be notably diminished. It would also be better to have the letters printed in white on a black ground than the reverse which obtains at present. The time taken to recognise a letter printed in black on a white ground was nearly ten times longer than that taken to recognise the same letter printed in white on a black ground. M. Broca and M. Sulzer had also inquired into the best forms of letters, both capitals and "lower case," and they gave examples. They had only made researches into the simple act of reading single letters and the reading of groups of letters and of complete words was still to be inquired into. In the case of words it is very probable that all the letters are not separately analysed by the reader.

The Syndicate of Medical Men of the Seine and the Tramway Company.

The First Chamber of the Civil Tribunal of the Seine has just decided a case in which an action was brought by the Syndicate of Medical Men of the Seine against the tramway company. The complaint of the syndicate had reference to a notice posted in the depôts of the company and the action was brought to obtain the removal of this notice together with the payment of 1000 francs damages. The notice was to the following effect. "In case of serious illness or accident requiring immediate medical aid the patient, in the absence of the company's medical officer, may send for the nearest medical practitioner, but he will have to give immediate information, either verbally or in writing, to the official in charge of his depôt. After having been visited by the company's medical officer the patient will have to pay for every other visit made by an outside medical man." The syndicate maintained that this notice was at variance with the law relating to accidents to workmen, for this law entitles the injured workman not only to choose his own medical attendant but also to recover from his employer a definite proportion of his medical expenses. The workmen would therefore be deprived of a right which belongs to them and the interests of the medical profession of the Department of the Seine would be affected, for they would be deprived of a portion of their patients. The company replied, in the first place, that the syndicate was not entitled to bring the action, which. in fact, did not involve any corporate interest, because several of the medical officers of the company belonged to the syndicate, and, in the second place, that the claim was unjustifiable because the notices only referred to the operation of the company's medical service and its sick fund and did not refer to the accidents to workmen provided for by the law of 1898. The tribunal has found that the syndicate has not made out its claim and is not entitled to take action because it does not act on behalf of a purely collective interest. The syndicate has therefore been non-suited.

Dec. 1st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Emperor's Health.

ALTHOUGH it has been announced that no further reports on the Emperor's health would be necessary an additional bulletin was issued on Nov. 25th by Professor Schmidt, Dr. Leuthold, and Dr. Ilberg. This bulletin is to the following effect. "The wound on the left vocal cord has healed since Nov. 19th His Majesty has been advised to spare his voice till the cicatrix has become stronger. Laryngeal massage and exercises have now been commenced and we hope that His Majesty within a few weeks will be able to use his voice as before." The massage is performed by Dr. Spiess of Frankfort, Professor Schmidt's former assistant. The recent bulletin, though quite satisfactory, is not so distinctly optimistic as the former ones and obviously a convalescence of longer duration than had been anticipated will follow. His Majesty walks daily in the park at Potsdam but has not yet appeared in public. The reports as to a visit to the south of Europe are not denied by the court journals, though, of course, ample information is not given. Professor Schmidt is said to have left Berlin for Frankfort but will return within a week. The rank of Real Privy Councillor has been conferred on him by the Emperor. This rank, with which is associated the title of Excellency, is the highest distinction open to civilians and is held by only a few medical men—namely, Professor von Bergmann, Professor von Behring, and Professor von Esmarch.

German Sanatoriums in Madeira.

Sanatoriums for consumptives will be established on the island of Madeira by a German committee of which Prince Hohenlohe is the president. The committee already possesses a concession from the Portuguese Government on the condition that 20 per cent. of the patients shall be Portuguese who are to be received free of charge. A commission consisting of Professor Fränkel and Professor Pannwitz of Berlin [illegible] the Queen of [illegible] emen advised [illegible] ertain height above the sea but not actually in the mountain region as had been proposed by some. The commission visited one of the highest peaks of the island and considered that sanatoriums situated at this height would have to be closed during the winter, whilst at a lower level they might be kept open all the year round. The sanatoriums will be constructed and managed in accordance with German ideas. In addition to the sanatoriums for consumptives the committee intends to build a vast establishment for sufferers from other chronic diseases and for convalescents where hydrotherapeutics, mechanotherapeutics, and various other systems of treatment will be a principal feature. The institution will be situated close to the beach so that visitors may have ample opportunity for sea-bathing even during the winter months. A fear has been expressed that this establishment might eventually degenerate into a kind of Monte Carlo where roulette and other forms of gambling might be indulged in, but Professor Fränkel, writing to the *Deutsche Medicinische Wochenschrift*, mentions that he is authorised to state that gambling will be strictly prohibited in the sanatoriums.

Hysterical Somnolence.

A remarkable case of hysterical somnolence is reported in the daily press. A woman, now 44 years of age, had an accident about 20 years ago by being thrown out of a carriage. She complained of severe headache and fell into a sleep, from which she only awoke after several months and was apparently then quite well. Two years afterwards, however, she again became somnolent, this second period lasting about twice as long as the first. Prominent medical men were consulted but declared the case to be obscure. She soon fell asleep again and only awoke a week ago, this period of sleep lasting about 17 years. A fire had broken out in the neighbourhood of the patient's residence and she was so much impressed by the general alarm and by the glare of the conflagration that she suddenly rose and spoke to her family. She had a full remembrance of past events. She wanted to speak to her mother, who had meanwhile died, and she recognised her friends. She was, of course, very emaciated and weak but her bodily functions are said to be quite normal. During her somnolence she was nourished by light food, soups, vegetables, and meat and the family noticed that she moved about in bed when meal times arrived. She even refused to eat if she happened to dislike what was offered her. The case must of course be regarded as one of hysteria, although hysterical somnolence of such a duration is very uncommon.

The Behring Institute.

A Behring institute, after the pattern of the Institut Pasteur at Paris, will be established by the Government. The new institute, in addition to its scientific work, will undertake the wholesale production of sera of every kind and especially of antidiphtheritic serum. The *Vossische Zeitung* rightly observes that the decision of the Government comes rather late. About ten years ago Professor Behring asked the Government for financial assistance in his very expensive studies on immunisation. This request being refused he was obliged to apply to the Höchster Farbwerke, the largest chemical manufactory in Europe, which liberally provided him with the necessary funds on the condition that they should have a monopoly of the sale of Professor Behring's serum. The prices charged were rather high and it is to be hoped that serum will become less expensive now that the Government has undertaken its production.

Nov. 30th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Convention of Railway Surgeons in New York.

THE thirteenth annual meeting of the New York State Association of Railway Surgeons was held recently at the New York Academy of Medicine. Dr. Henry Flood, president of the association, was chairman. Among the papers read was one on Car Sanitation by Dr. James A. Exton and one on the Diagnosis of Injuries of the Hip by Dr. Wisner R. Townsend. Dr. C. B. Herrick read a paper on the Diagnosis of Injuries to the Head. Dr. W. B. Coley presented a paper on Traumatism as a Factor in the Causation of Hernia and said that his experience at the Hospital for the Ruptured and Crippled had convinced him that traumatism as a cause of hernia was very rare; out of 15,000 cases he had seen at the above-mentioned institution only four had resulted from external accident. Dr. A. J. Gilbert asserted that hernia had cost the railroad companies more money than had any other form of injury and that "it is a frightful source of fraud, particularly among employés."

Yellow Fever in Mexico.

A considerable amount of alarm exists in Texas owing to the prevalence of yellow fever in Mexico. The statement was made a short time ago that the epidemic of the disease now raging in Mexico has gone beyond the control of the Mexican health authorities. The long spell of warm weather and the negligence exhibited by the lower classes of Mexicans in reporting cases of yellow fever to the health authorities has caused, it is said, the disease to be spread far and wide. The medical officer of health of the State of Texas fully appreciates the gravity of the situation and a few days ago said that he would invite General Wyman, the chief of the United States Public Health and Marine Hospital Service, together with the representatives of the health departments of Louisiana, Mississippi and Alabama, to accompany him to Mexico in January next for the purpose of holding a conference with the Superior Board of Health of that country to decide upon a concerted plan of action which would prevent the occurrence of another epidemic of yellow fever in Mexico and the spread of the disease to Texas and to the Southern States of America next season. Efforts will be made to induce the health authorities of the districts in Mexico in which the disease is epidemic to improve the sanitary conditions therein. The authorities will be also urged to compel the ignorant and superstitious Mexicans to report all cases of yellow fever. Failure to do this has been one of the main factors in the rapid spread of the malady in Mexico during the present season.

Care of Criminal Epileptics.

The Conference of Charities and Correction of New York State is in session at Buffalo. The report of the committee on the Treatment of the Criminal by Frank W. Robertson, superintendent of the State Reformatory, Elmira, was read by Dr. E. V. Stoddard, President of the State Board of Charities. In regard to the care of criminal epileptics the report demands suitable provision for this class, "some of whom," it says, "while not by transfer or otherwise inmates of hospitals for the insane, are yet not fit cases for the prisons." The report makes the suggestion that provision for the care of the insane might be so amended as to insure the transference of those suffering from mental disorders to the Dannemora State Hospital.

Nov. 23rd.

Obituary.

GILBERT KIRKER, M.D., M.CH.R.U.I., M.R.C.S. ENG.,

FLEET SURGEON, R.N.

THE medical department of the Royal Navy, and his many friends in the medical profession, heard with profound regret of the death of Fleet-Surgeon Gilbert Kirker at Haslar on Nov. 24th. Whilst performing an operation, an excision of the hip-joint, on Nov. 14th, he cut his finger. On the following day he amputated a thigh and on the third day noticed a slight inflammation of the wounded finger. The finger was incised and all signs of local trouble quickly passed away. But on Nov. 18th he had rigors and high fever and was placed on the sick list; toxic hæmaturia followed with suppression of urine and six days later he died. Fleet-Surgeon Kirker was an Ulsterman and studied at the Belfast Academy, of which the principal was Dr. R. Bryce, uncle of the Right Hon. James Bryce, M.P., and subsequently at Queen's College, Belfast, where he matriculated in 1872. He greatly distinguished himself as a medical student and in 1876 graduated at the Royal University of Ireland as M.D. In the following year he came to England and after becoming a Member of the Royal College of Surgeons of England attached himself to the Turkish side as surgeon in the Russo-Turkish war. At the end of the operations he returned to England and in 1879 entered the medical department of the Royal Navy. At the entry examination he obtained first place and at the end of the Netley course of instruction he carried off the Parkes prize in hygiene. He was then appointed to H.M.S. *Iris* on the M ation and took part in the Egyptian war of 1882, for which e was awarded the Egyptian medal and the Khedive's ronze star. Later he was appointed assistant professor at [aslar where he worked with unremitting energy until he as appointed staff surgeon in 1891 when he was commissioned to H.M.S. *Phaeton* and gained the Gilbert Blane gold ıedal for the excellence of his professional records on oard that vessel. For some time he was in charge f the Royal Naval Hospital at Esquimalt where he vailed himself to the full of many opportunities for oing good work. He afterwards returned to Haslar, here at the time of his death he held the posts of ıstructor to surgeons on entry at the Royal Hospital and f principal medical officer to one of the surgical sections. . man of fine physique and attractive appearance. Fleet-urgeon Kirker at school, at college, at the Royal Victoria Iospital, Belfast, where he was formerly resident, and ıroughout his distinguished naval career was always reatly liked, his manly character and straightforward ctions making him an especial favourite. Throughout is career he took a keen interest in all hygienic and urgical work, his active brain seeking how he could 'improve," for it was always his idea to get "to he bottom" of everything that he was interested in nd many small inventions were the result, the most *asting being the Kirker ambulance sleigh which is now* ully recognised as the most useful method of transporting he sick and wounded on board ship, having been intro- [illegible] Navy, the Japanese Navy, [illegible] Association he was well [illegible] ›r the Navy, Army, and ımbulance section last year at Manchester and doing much o make it a success. His early death is a very great loss ıot only to his many personal friends but to the whole Vaval Medical Service and *it is to be regretted that his* istinguished career had not placed him in a higher rank han that he held, *for it is* well known that his abilities vere fully appreciated and that if he had been spared hey would have been recognised in promoting him to the ıigher ranks very shortly. He married the daughter of a vell-known solicitor in Dundalk, and his widow and children two boys and two girls) will have the deepest sympathy of ll the friends of their deceased relative in the great and *rreparable loss which they have sustained.*

WILLIAM DINGLEY, M.R.C.S. ENG., L S.A.

WILLIAM DINGLEY of Elm Bank, Camden-road, London, vho died on Nov. 17th, was born on Nov. 9th, 1828, at Sherborne, Dorset, and was educated at the well-known chool of his native town. At the age of 16 years he chose he medical profession as his career in life and was articled o a surgeon in Sherborne for three years. At the end of that ime, in October, 1847, he entered as a student at St. Bartholomew's Hospital when Sir William Lawrence was senior urgeon and Sir James Paget was junior assistant surgeon. After qualifying in 1850 he saw a year's practice at some ron-works in South Wales before starting in general ›ractice. After a short sojourn in Trowbridge he came to London and entered *into partnership with his cousin* and ater with his sons in Bloomsbury and Camden-road. Blessed with a good constitution he stood the strain of a aborious practice for 49 years without a day's illness. His nidwifery practice was large and his help and advice were nuch sought by brother practitioners in difficult cases. He was an earnest Christian with a high standard of conluct. He was much beloved and trusted by his patients, his hatred of pretence and unswerving devotion to duty being ›bvious to them.

Mr. Dingley was a wide general reader, at the same time keeping himself informed on *current medical literature* and ›ractice, and was treasurer of the North London Medical and Chirurgical Society, at the meetings of which body he spoke with quaint force fro [illegible] lf a century. His remains [illegible] me- tery on Nov. 21st. He [illegible] the [illegible] On [illegible] address of the *minister upon* a life which had been so full of human service in all its relations.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. J. Chisolm, formerly professor of ophthalmology and otology in the University of Maryland, Baltimore.—Dr. Brun, surgeon to the hospitals of Paris.—Dr. Francesco Folinea, a Naples surgeon—Dr. Friedrich Goll of Zürich, whose name is known in every medical school in the world in connexion with the columns of the spinal cord. He was born in Zürich in 1829. He studied under Kölliker and Virchow in Würzburg and under Claude Bernard in Paris and then settled down in practice in his native town.

Medical News.

UNIVERSITY OF OXFORD.—At the examination in Preventive Medicine and Public Health (D.P.H.) held recently the following gentlemen were successful:—

[illegible]

In a Congregation held on Nov. 19th the following degrees were conferred:—

Doctor of Medicine.—John Wood, Pembroke College, and Peverell Smythe Hichens, Magdalen College.

In a Convocation held on Nov. 24th the following decree was proposed and carried *nemine contradicente*:—

[illegible] decree.

UNIVERSITY OF CAMBRIDGE.—On Nov. 26th the following degrees were conferred:—

Bachelor of Medicine.—H. A. Cutler, Clare.
Bachelor of Medicine and Bachelor of Surgery.—F. Bryan, King's C. V. Bulstrode, Trinity; and W. H. Fisher, Emmanuel.

Professor Howard Marsh and Dr. D. MacAlister have been appointed members of the State Medicine Syndicate and Dr. J. Griffiths a member of the special board for medicine. Mr. F. C. Parsons has been appointed an examiner in Human Anatomy in the place of Dr. A. Birmingham who is unable to examine this term. The Graces for the appointment of a syndicate to consider what changes are desirable in the studies and examinations of the University were on Nov. 26th adopted by large majorities in the Senate. The examiners in State Medicine for the ensuing year are: Professor G. Sims Woodhead, Mr. J. E. Purvis, Dr. J. F. W. Tatham, Dr. J. Lane Notter, and Dr. R. D. Sweeting.

TRINITY COLLEGE, DUBLIN.—At the Final Examination at Michaelmas the following gentlemen passed:—

Section A.—H [illegible] iam J. Powell, Cyril H. M [illegible]
Surgery.—Th [illegible] C. Hallowes, Philip S. [illegible] Willington, Cecil J. Wyatt, and Thomas J. Crean.

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* Dr. N. Berend has been appointed *docent* of [illegible] moted to the Ordinary Professorship of Pharmacology and Therapeutics and Dr. Troisfontaines to the Ordinary Professorship of Dermatology.—*Marburg:* Dr. Erich Opitz of Berlin has been appointed Extraordinary Professor of Gynæcology.—*Pavia:* Dr. Ercole Pusateri has been recognised as *privat-docent* of Psychiatry and Dr. Tommaso Busacchi as *privat-docent* of Surgery.—*Prague (Bohemian University):* Dr. Alois Velich [illegible] ordinary Professor of General [illegible] Dr. Ottokar Frankenberger, [illegible] Laryngology and Rhinology; and Dr. Emanuel Formánek, Extraordinary Professor of Medical Chemistry.—*Rome:* Dr. Arnaldo Pieraccini has [illegible] Psychiatry.—*Utrecht:* [illegible] cognised as *privat doce* [illegible] Dr. Julius Tandler has been promoted to an Ex [illegible] Professorship of Anatomy; Dr. Ferdinand [illegible]

Extraordinary Professorship of Pediatry; and Dr. Josef von Metnitz to an Extraordinary Professorship of Odontology.

MR J. J. UDALE, M.R.C.S. Eng., L.R.C.P. Lond, has been elected a member of the council for the metropolitan borough of Finsbury.

Donations and Bequests.—Under the will of Mr. George Harwood £500 are bequeathed to the London Hospital; £500 to the treasurer of the City of London Hospital, Victoria park; £500 to the North-Eastern Hospital for Children, Hackney; and £500 to the Metropolitan Hospital, Kingsland-road.

Medical Circulating Library.—It may be useful to announce that Mr. H. K. Lewis, of Gower-street, London, W.C., whose old-established medical circulating library is well known to our readers, is now prepared to undertake the weekly delivery of books at subscribers' residences and to arrange for their re-collection.

A New Method of Sharpening Knives.—The *Engineer* of Nov. 27th states that a German experimenter named Bernhard has discovered that aluminium may be used for putting an edge on fine-cutting instruments such as surgical knives or razors and that it acts exactly like a razor-hone of the best quality. He found that when steel was rubbed on it the aluminium disintegrated with the formation of a powder of a somewhat greasy nature which clung to the steel with great tenacity and assisted in cutting away the hard surface of the metal.

Presentations to Medical Practitioners.—Mr. J. Rowlands Essex, M.R C S. Eng., of Pontypool, Mon., medical officer of health of Panteg, who has recently resigned his appointment as surgeon to the Pontypool town forge tin and iron works, has been presented by the workmen with a marble timepiece and a smoking cabinet. Mr. Essex was for 27 years surgeon to the works with which his father was connected in the same capacity for 51 years.—Mr. William Grant, M.B, C M. Aberd., who for nine years has been assistant surgeon to the Treherbert (Glam.) collieries, has been presented with a gold watch and chain and a purse of gold on the occasion of his leaving the district owing to ill-health.

Irish Medical Schools' and Graduates' Association.—Dr. P. S. Abraham, the President of the Irish Medical Schools and Graduates' Association, took the chair at the autumn dinner on Nov. 25th at the Trocadéro Restaurant, Piccadilly-circus, London. Dr. Abraham, in the course of a reply to the toast of "The Association," proposed by Professor William Graham of Dublin, observed that the association had done good work. It had raised the position of Irish medical men throughout England. It had helped to show those concerned that the attempt to exclude Irish graduates and diplomates from public appointments in England was a failure. Happily at the present time but little of the former spirit of intolerance prevailed. A more liberal view was now taken and the old grievance that candidates with Irish degrees were ineligible for appointments on the honorary staff of English hospitals was being rapidly removed. This improvement was due to a great extent to the influence of the Irish Medical Schools and Graduates' Association. Another interesting matter was touched upon by Mr. J S. Whitaker, organising secretary of the British Medical Association, who replied to the toast of "The Guests." He said it was his duty to pay visits to many parts of England, Ireland, and Scotland. When in Dublin he was told that the best investment John Bull could make was to secure the goodwill of the Irish and that had been recognised by the British Medical Association. That body had decided that assistance should be given to the Irish Poor-law dispensary doctors in their fight against the wrongs to which they were subjected. He pointed out that everyone who heard him at that dinner could be of assistance in the struggle of the Irish dispensary doctors by preventing medical men from filling up the posts vacated by them and in that manner reform would be hastened. Another subject of public concern was introduced by Surgeon-Major W. Moyle O'Connor, second in command of the Royal Army Medical Corps Militia, who, in the course of responding to the toast of "Our Defenders," proposed by Sir J. W. Moore, contended that the Royal Army Medical Corps Militia should be permanently employed in home billets. In that manner, he explained, the officers of the Royal Army Medical Corps would be available for service abroad in their full strength. This, he considered, was the only means by which officers could be encouraged to join the medical service of the Militia. The corps had been increas from 800 to 1600 men and was the largest embodied unit that nature.

Singular and Unsuccessful Claim against Dentist.—At Gloucester county court last week a clai for damages was brought by a carpenter named Freem against Mr Ebenezer Apperley, L.D.S. R.C.S. Eng. T plaintiff claimed £161 in circumstances which had be mentioned in a previous action in October when the ju could not agree and a new trial was decided upon. appears that towards the end of December last the plain was suffering from toothache and went to the defendan a properly qualified dental surgeon, whose son stopped t tooth with cotton-wool steeped in a preparation of cocain When the plaintiff got into the street, according to t evidence, he felt giddy and on Christmas Day while eati some rice pudding the stopping came out of his tooth a he swallowed it with the pudding. After that he becar very ill and the suggestion was that Mr. Apperley, ju had put an overdose of cocaine upon the cotton-wool whi formed the stopping and so had caused the illness. Aft hearing the evidence for the plaintiff his honour agre with the counsel for the defendant that there was no ca to answer and non-suited the plaintiff with costs.

The Open-air Treatment of Pulmonary Tuberculosis.—Proposed Sanatorium for Middlesex.—S Ralph Littler, K.C., presided at a meeting at the Middlese Guildhall on Nov. 27th, held for the purpose of considering the question of establishing an open-air sanatorium fo Middlesex. Sir William H. Broadbent, after remarking that he would do the utmost in his power to promote the establishment of such a sanatorium, pointed out that London was the worst provided with sanatoriums of all large towns in the kingdom, while at the same time it was overwhelming in its demands for the treatment of consumptive cases. It would therefore be no advantage to Middlesex to share a sanatorium with London. On the motion of the Bishop of Kensington, seconded by Mr. Bott, it was decided that a sanatorium should be established and an executive committee was appointed for the purpose of collecting funds and of negotiating with public bodies. This committee wi consist of the following gentlemen: Mr. Montagu Sharpe, Mr. Bott, Dr. Kenwood, Dr. Benjafield, Mr. J. Box, and Mr A. W. W. King. Sir Francis Cory-Wright was appointed treasurer and Colonel Gerard Clarke was elected secretary Lord Rothschild and Mr. Leopold de Rothschild have each promised a donation of 200 guineas towards the proposed building.

Association of Physicians and Surgeons (Society of Apothecaries).—The first meeting of the members of this society since its incorporation took place in the hall of the Society of Apothecaries in Blackfriars, in the City of London, on Tuesday, Dec. 1st. The meeting was advertised to include the Licentiates of the Apothecaries' Hall of Ireland, and the chair was taken by Mr. A. Rivers-Willson (Oxford). The following gentlemen had written wishing to join the Association of Physicians and Surgeons of the Society of Apothecaries: Mr. A. M. Sheild, Mr. C Stonham, Mr. W. Bruce Clarke, Mr. F. J. Steward, Mr. J A. Ryan (Glasnevin), Mr. J. Evans (Dublin), Dr. Alexis Thomson (Edinburgh), Dr. R D. Purefoy (Dublin), and Sir Charles A. Cameron (Dublin). The meeting was attended by about 30 medical men. The proceedings commenced by the Chairman moving the following:—

> That the Association of Physicians and Surgeons, Limited, having for its objects the professional advancement of the Licentiates of the Society of Apothecaries of London and of the Apothecaries' Hall in Ireland, deserves the encouragement and cordial support of all Licentiates of the Corporation.

Turning to the Master of the Society of Apothecaries who was seated near, the Chairman submitted for the consideration of the society the proposal that the Licentiates should have the title "Licentiate in Medicine, Surgery, and Midwifery." The motion was seconded by Mr. George Jackson (Plymouth), one of the Direct Representatives on the General Medical Council, who observed that a Licentiate of the Society of Apothecaries might use the title of physician and surgeon. But that right was not expressed in the letters L.S.A. What ought to have been done was that the Society of Apothecaries should have been amalgamated with the Royal Colleges of Physicians and Surgeons The only alternative that now remained was for the Society of Apothecaries to ask Parliament to consent to an alteration of the title Mr A. Mowbray Upton, clerk to the Society of Apothecaries, spoke in favour of the objects of the Association of Physicians and Surgeons of the Society Dr Clarence Cooper, the Master of the Society, pointed out that it had been contended by many that the Society had the power to grant the title of Fellow or any other title to anyone who had passed their examination for the Licentiateship of the Society The usual votes of thanks concluded the business of the meeting after the motion submitted by the Chairman had been unanimously adopted

MIDDLESEX HOSPITAL.—At a meeting of the court of governors of the Middlesex Hospital, held on Nov 27th a report was submitted which stated that since the last meeting the constitution of the board had been strengthened by the addition of Prince Francis of Teck and the Hon Oliver A. Borthwick. The amount required for alterations and other current expenses had been approximately ascertained to be about £15,000, and in view of the existing depression in the stock market it was thought advisable to obtain a loan of £15,000 from the bankers The new clinical and bacteriological laboratories had been in working order for rather more than 12 months and could already show a satisfactory record of work done The total number of medical, surgical, and obstetrical patients treated during the past half year was 2079 with the following results discharged relieved 1517, discharged unrelieved, 125, left at own request, 29, deaths 136, remaining in the hospital on Oct 1st, 272, total, 2079 In the out-patient [illegible] were treated, the total number of [illegible] giving an average of 2 2 attend- [illegible] an average of 218 patients seen daily The council of the Metropolitan Hospital Sunday Fund had now recognised the cancer wing as a separate institution and had this year made a grant of £325 to the funds During the past half year the number of admissions to the cancer wing had been 69 and the deaths 51, whilst 18 patients had discharged themselves The number of outpatients had been 101, with a total attendance of 382

GLASGOW UNIVERSITY CLUB, LONDON.—Sir William Taylor, K C B, Director-General of the Army Medical Service, presided on Nov 26th at the half yearly dinner of the Glasgow University Club, London, which was held at the Trocadéro Restaurant Piccadilly-circus, London Among those present were Sir George Hare Philipson, Sir Charles B Ball, Sir John Batty Tuke, Surgeon General H Skey Muir, C B, Dr Guthrie Rankin, Dr C O Hawthorne, and Dr. D C McVail The toast of "The Imperial Forces" was proposed by Sir George Philipson who in the course of his remarks paid a high compliment to the Glasgow companies of the Royal Army Medical Corps. These companies originated in the University of Glasgow and were officered by Glasgow graduates Surgeon General A. H Keogh, C B, who was called upon to reply, observed that the Army Medical Service had started on the path of progress and reform Before the reorganisation of the department there were three Glasgow graduates at headquarters After the reorganisation they found that there were three more Glasgow graduates there and in that way the service was specially indebted to the University of Glasgow Sir William Taylor next proposed the toast of "The University and the Club' He said that it was not known perhaps to everyone how the Zachary Boydleian Library became the property of the University of Glasgow Zachary Boyd composed a poetical version of the Bible and the following was a fair example of his talents as a poet "Was not Pharaoh a rascal' That was the first line of a couplet The second line was "He wouldn t let the children of Israel go with their wives and families, their bags and baggage, 40 days' journey into the wilderness for to eat the Pascal" Boyd was anxious to have his book printed and published and after being refused by the Universities of Oxford and Cambridge the undertaking was accepted by the University of Glasgow That institution fulfilled its promise by printing and publishing two copies one was kept in the Boydleian Library and the other was presented to Zachary Boyd After reviewing the celebrated men who had come from the University of Glasgow Sir William Taylor concluded by saying that the Glasgow University Club existed in London because it was the natural result of one of the laws of nature that wherever two or three Scotch were gathered together they stuck to each other and took counsel for the common good of the race The other toasts were those of "The Guests" and "The Chairman" The former was effectively dealt with by Dr Rankin and the latter was proposed in a witty speech by Mr A. A. Jack In addition to the entertainment afforded by the eloquence of the orators those present were treated to Scotch stories by Dr G Ogilvie and to Scotch songs from several talented singers

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions *should be addressed.*

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

The Bradshaw Lecture

ON

CANCER AND ITS ORIGIN.[1]

Delivered before the Royal College of Surgeons of England on Dec. 9th, 1903.

By HENRY MORRIS, M.A., F.R.C.S. Eng.,

SENIOR VICE PRESIDENT AND CHAIRMAN OF THE COURT OF EXAMINERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; SENIOR SURGEON TO, AND CHAIRMAN OF THE CANCER INVESTIGATION COMMITTEE OF, THE MIDDLESEX HOSPITAL.

Mr. President and Gentlemen,—I have chosen cancer, meaning thereby both carcinoma and sarcoma, as the subject of this lecture for several reasons. 1. The discovery of the microbic origin of certain diseases has led to the most painstaking efforts to ascertain, by means of modern bacteriological methods, the cause or causes of cancer. What the result has been I shall endeavour to show. 2. The premature publication of immature and disputable conclusions and of crude and impossible theories has unfortunately aroused false hopes and has attracted the impatient and somewhat too credulous attention of the general public to everything connected with the word "cancer." It would be well, if it were possible, to allay these consequences. 3. No lecture specially on cancer has been given at this College since the last Morton lecture was delivered in May, 1894. 4. This Royal College has for the first time in its history recently embarked upon a great and important scientific inquiry by, conjointly with the Royal College of Physicians of London, undertaking the general direction and control of what may be called a national movement for the investigation of cancer, and it may be of interest to review, although very imperfectly, the general position of the subject at the commencement of this undertaking by the Royal Colleges.

In the 93 years since the foundation of the *Hunterian lectures* cancer, considered on general lines, not simply as it affects some particular organ or part, was never selected, so far as can now be ascertained, as the subject of a Hunterian lecture. In the Arris and Gale series which, like the Hunterian, was commenced in 1810, Sir James Paget is alone, he having taken for his course of lectures Malignant Tumours in 1852. In the Erasmus Wilson series Mr. H. T. Butlin in 1880 and 1881 lectured on the Relations of Sarcoma to Carcinoma. In 1882 Mr. F. S. Eve gave two lectures on the Etiology of Tumours, and last year (1902) Dr. C. P. White delivered three lectures on the General Pathology of Tumours. Of the Bradshaw lectures only one has [illegible] and that was given by Sir William Savory in 1884, th [illegible] hology of Cancer." Through t [illegible] John T. Morton of Caterham [illegible] were instituted in this College with the hope of advancing our knowledge of cancer and the treatment of cancer. The first of these Morton lectures on Cancer and Cancerous Diseases was delivered in 1887 and the last in 1894.

I had thought of prefacing what I have to say to-day on Cancer and its Origin by a short account of the leading views which have been expressed in this country during the last 30 years about cancerous affections. To this end I studied and made epitomes of all the lectures bearing on cancer which have been delivered in this College during that period, as well as [illegible] ancer which have taken place [illegible] in London in 1874 and the [illegible] iese lectures and debates contain all that was known about cancer and of the theories as to its causation up to the date of their publication, but I found that even the briefest *résumé* of them would extend far beyond the limits of an hour's discourse. With regard to the theories of causation of malignant diseases which have been published since the delivery of the last of the Morton lectures even a mere statement of them would occupy much time and any attempt at a complete account would take up several hours.

Several of the views put forward are mutually exclusive of each other. Thus while some persons attribute to arsenic, some to sugar [illegible] neats the increase of cancer [illegible] tive agent and molasses as a [illegible] common salt and the chlorine [illegible] the saccharomycete to which [illegible] due—excess of water and [illegible] articles of diet, climate, soil, cancer houses, occupations, mental worry, nationalities, &c., must be set aside as altogether inadequate to be the fundamental and essential cause of the origin of cancer. They at most are merely predisposing or exciting causes, but not one of them is the true, immediate, and essential factor. Injury, irritation, or inflammation may bring about a condition of the tissues favourable to the extension of cancer and may also excite the real factor into action, but, as we are all daily witnessing, these [illegible] primary tumour, but as a general carcinomatosis or sarcomatosis.

Dr. Alexander Katz of Hamburg in a paper read before the Berlin Cancer Committee in January, 1902, grouped the alleged causes of cancer formation into the entogenous (or intrinsic) and the ectogenous (or extrinsic). By entogenous causes are understood certain spontaneous and anomalous changes within the organism; by ectogenous causes those derived from outside the body. The entogenous embrace, amongst many others, the causes alleged under the two important theories of Thiersch and Cohnheim. Thiersch's theory and all the variants of it may appropriately be called the "lost balance theories" in contradistinction to the "matrix" or "tumour germ" theory of Cohnheim and his followers. According to Thiersch the beginning of a tumour formation is due to a loss of balance between the epithelial cells and the connective tissue. In carcinoma, for example, this loss of balance occurs during advancing age by the degeneration of the connective tissues and results in an invasion of these tissues by the epithelial cells. In other words, the theory supposes that in its origin carcinoma depends on some cause which produces as age advances a local impairment of resistance, a retrograde process in the sub-epithelial structures, whilst the epithelium maintains its activity or, it may be, acquires a special vigour. This view, Katz says, has never gained a foothold and is only of value in that by means of it the age limit of cancer can be explained. Katz's statement is, however, at variance with the somewhat considerable importance which has been attached to Thiersch's theory, at any rate in this country, for it was accepted as probable by Coats and Maylard in the Glasgow debate; it was adopted in his Morton lecture by Sims Woodhead, who corroborated it by what he found on microscopic examination of the tongues of old people; in principle it has been quite recently supported by Foulerton and by Woods Hutchinson; it appears also in the theory of "unstable equilibrium" of Powell White; and its influence is also traceable in certain other modern theories—as, for example, the "anaplastic" theory of Hansemann.

[illegible] to a biological change in the [illegible]

Thiersch's theory and the other "lost balance theories" are all open to the same objections which the "localists" brought against the "constitutional" theory. To hold that the formation of carcinoma is due to a loss of the normal balance between the epithelium and the connective tissue, the result of advancing age, is to imply the existence of an "all-pervading condition" of the connective tissues and yet that this "all-pervading condition" can give rise to a disease which [illegible] at least is strictly localised. A disease so origina [illegible] disease than one due to [illegible] and such a theory of cancer is open to all the same arguments as the "blood theory." Indeed, Paget, after pointing out that there are not many things which do "all-pervade the body" fixed upon the "all-pervading blood," rather than the "all-pervading connective tissue," as the medium of the supposed "virus," merely, as he said, "because at any rate we can then hold to our study by some sort of analogy with things that we recognise as blood diseases." If the theory was correct cancer should commence, not as a solitary tumour, but as a general carcinomatosis or sarcomatosis.

---

[1] The paragraphs in smaller type were those which time would not allow the lecturer to read.

But these "lost balance theories" have to meet the further difficulty that carcinoma is continually progressing laterally as well as downwards by, as it is commonly stated, "the irregular and rebellious growth of the neighbouring epithelium." So that the disease does not consist, as these theories imply, merely in an invasion of the weaker by the stronger tissue, but there is likewise a retrograde and subversive metamorphosis produced in the stronger by the stronger—i.e., in the epithelium by the epithelium. Foulerton by substituting chronic inflammation and irritation for senility as the cause of the epithelium transgressing the limits of the basement membrane (and therefore of the loss of normal balance between the epithelium and the connective tissue) escapes some of the arguments against the constitutional theory; but he does not explain why it is that chronic irritation causes carcinoma in some cases and not in others, and in some parts of an individual but not in other parts which have been similarly and equally irritated; nor does he explain the origin of carcinoma where there has been neither traumatism nor chronic irritation.

Woods Hutchinson, by assigning the origin of cancer to a matrix of mature cells, which cells after becoming "detached" by a process of destructive elimination, revert to their ancestral or embryonic type, is to some degree open to the same objections by holding that whole organs, such as the uterus and mamma, are thus detached from the rest of the organism. Why, for instance, if this theory is correct, do we not frequently meet with multiple primary carcinomata in the female breast? Why, in the uterus do we not commonly find multiple primary carcinomata—one or more malignant neoplasms in the fundus, one or more in the cervix uteri, each one corresponding in structure with the glands of the part of the organ in which the neoplasm has arisen?

There are other entogenous theories as to which I cannot do more than just barely allude. Mr. Jonathan Hutchinson, for example, considers now, as formerly (see Glasgow debate), cancer as simply "a modification of the inflammatory process, which again in its turn is only a modification of that of normal nutrition"; he regards the causes which give proclivity to all malignant new growths as nearly identical, the chief of them being senility, chronic inflammation, and local irritation, and thinks that every human being, nay, every organism possessing tissues capable of inflammatory change, is liable to the different forms of cancerous disease. The late Mr. John Marshall, who delivered the third Morton lecture, and Dr. J. Inglis Parsons have advanced the theory that cancers, and, indeed, all tumours, "are in the first instance composed of cells formed in the normal process of repair, but that, having escaped from the control of the nervous system, they take on an independent life and continue to proliferate and develop without check just as all living cells are capable of doing *ad infinitum* under favourable conditions."[2] Mr. H. L. Lack's theory was that carcinoma formation is due to the migration of normal epithelium, by means of the lymphatics, to various parts and organs where the cells lodge and proliferate indefinitely. One of his experiments, and only one, seemed to support this view—and no similar or corroborating result has ever since been obtained. Dr. Jules Félix and Dr. Robert Bell have each laid great stress in recent works on the sinister influence of uric acid and the gouty diathesis in promoting the condition of the tissues which enables cancer to develop.

I must pass now to a brief consideration of the ectogenous group of conjectural causes. These are: (1) the various forms of injury, chronic irritation, and chronic inflammation, &c.; and (2) micro-organisms. Great importance has been attached by Virchow and many others to chronic irritation as a causative factor in cancer; and it is certainly needful for us all to bear in mind the pernicious rôle played by the clay pipe, the carious tooth, and many and various agencies of the kind in provoking the development of cancer. But not one of them can take rank as the essential and unconditional cause of malignant disease; that is, as the factor, without which cancerous diseases cannot arise, though they are unquestionably amongst the agents which excite the real factor of tumour formation into activity, and as such they must be referred to again in connexion with the "*tumour germ*" theory.

The Microbic Theories.

The theory of the microbic origin of cancer still occupies the very forefront of cancer research. There are not wanting, however, indications that it is on the wane and that it may soon come to be described, as indeed Hansemann in his recent work has already spoken of it, as "belonging to history." The search for a specific micro-organism of cancer dates back to the early days of modern bacteriology. As soon as tuberculosis was removed from the list of diseases due to a so-called diathesis, by the discovery in 1882 of the bacillus tuberculosis, a very large number of scientific workers made it their aim to demonstrate, if possible, the existence of a corresponding micro-organism as the causative agent of carcinoma and sarcoma. Nedopil in a memoir published in 1883 was the first to sustain with conviction the microbic origin of cancer. No sign of a specific cancer organism had, however, at that time been demonstrated. But research soon led to the alleged discovery by different experimental workers of three classes of living agents—namely, bacteria, protozoa, and saccharomycetes and blastomycetes, or yeast fungi

The bacterial or schizomycetic theory.—Bacteria were the first organisms which were thought to be the cause of can Nepveu as far back as 1872 had found them in carcin and Rappin is said to have actually isolated a diploco both from epithelioma and sarcoma in 1886. During there appeared a number of writings by different inve gators who claimed to have discovered—either in cance tumours, or in the blood of cancerous persons—the mic of cancer, and to have isolated and cultivated it; and means of inoculation of the fluid culture to have cau the reproduction of the disease in animals. Scheu claimed to have isolated and cultivated a special bacte from carcinoma. Francke described a bacillus of sar which he differentiated from the bacterium found Scheuerlen in carcinoma. Schill stated that he successfully cultivated a bacterium from both carci and sarcoma. Others subsequently made similar clai whilst, on the other hand, several eminent observers arriving at the conclusion that many of the supposed m organisms were the factitious products of faulty techni and that such micro-organisms as had been actually covered played but a very subordinate rôle, if any, in evolution of malignant tumours.

The protozoic or psorospermic theory.—Before the year attention had scarcely at all been directed to the pres of sporozoa in human pathology, but between that date 1891 coccidia—a group of parasites belonging to class of protozoa—were found in a variety of organs of man, especially in the pleura, the inte epithelium, the liver, and the ureter, as well as in the m from the air passages of persons suffering from whoo cough. In 1889 and the following year a number of des tions were given by several observers of coccidia bodies having a great resemblance to the coccidium of liver of rabbits which they had discovered in carcino the skin, jaw, intestine, stomach, nipple and breast, pe and bladder, and other parts. These bodies were found in the nucleus and protoplasm of cancer cells. In appeared Schueller's monograph with the description of round or oval yellowish-grey or yellowish-brown pr of cancer, showing radiating striæ or cilia in their sur which he had discovered. In 1891–92 Ruffer found described bodies which he regarded as psorosperms in protoplasm of carcinoma cells. In the same and the f ing years other workers described similar results. In Gaylord published an account of certain spherical alleged by him to be cancer organisms, and von described a protozoal organism in the form of motile In a work just published Dr. Ludwig Feinberg argues for the animal nature of the cancer parasite, to he gives the name "histosporidium carcinomatosum." the other hand, many observers have asserted that all alleged cancer organisms are not psorosperms but the ducts of cell degeneration, or cell inclusions of leuco-, red blood discs, or are the result of irregular for indirect division of epithelial cells; and Ribbert br forward, amongst other objections, his ingenious and argument of "symbiosis," against the validity of microbic origin of cancer.

The blastomycetic theory.—The theory that carcinoma to infection by a vegetable parasite belonging to the bl mycetes or yeast fungi was first promulgated by W. R in 1890. Russell found certain small round bodies the cells of carcinoma, which retained the fuchsin stain sections of carcinomatous tumours had been treated carbol fuchsin, then decolourised with alcohol, and counter-stained with iodine green. These "fuchsin he regarded as yeast-like or "sprouting fungi." Pri Russell's paper the yeasts had been considered as in any pathogenic effect, but within a few years after, of yeast infection in man resulting in the formati granulomata, but not of malignant new growths, came recorded. The blastomycetic theory of the origin of has been since pursued chiefly by Sanfelice and who not only confirmed Russell's views but have gone further. Plimmer who was previously a strong support the protozoic theory and had, like Soudakewitch, koff, Ruffer, and others, described the cancer bodies protozoa, became a convert to the views of Russell, felice, and Roncali, whilst Sawtschenko, who was also verted, has recently described as representing yeasts same figures which he had formerly described as protozoa.

As in the case of bacteria and psorosperms, so with yeasts alleged to have been found in cancers, their na disputed by many observers. The "fuchsin bodies" of Russell were regarded by Cazin and Duplay as a certain form of cell degeneration (*globes hyalines*); by Nepveu as being derived from changes in the nuclei of leucocytes or in red blood corpuscles; or still oftener from the endothelial cells of the lymphatics; and by others they were considered to be due to degeneration of protoplasm or to atypical mitosis and phagocytosis; whilst Foulerton and Price Jones have pointed out three possible sources of fallacy as to the presence of yeasts in cultures obtained from malignant new growths, the chief of the three being contamination owing to the presence of yeasts or torulæ in the air of the laboratory.

---

[2] J. Inglis Parsons: Brit. Med. Jour., April 27th, 1889.

The failure of the microbic theories.—From a careful examination of [illegible] for and against the bacterial or blastomycetic nature of [illegible] the alleged bacterial or [illegible] postulates nor with [illegible] in the complete [illegible] alleged organisms in the [illegible] growth of which tumour [illegible] the multiplication of the [illegible] indeed the essential cause [illegible]ns. Apart from the fact [illegible] cultivating and inoculating [illegible] nature of the cancer bodies [illegible]; and even granting that [illegible] no evidence to show they [illegible] or sarcoma.

In short, neither fission fungus, yeast fungus, nor psorosperm—neither bacterium, blastomycete, nor protozoon—has up to the present moment been satisfactorily shown, in spite of years of patient study by many skilled workers, to be in any sort of causal relationship to these diseases. How different was the case of the tubercle bacillus! When Koch [illegible] his great discovery he was able to bring forward [illegible] of the correctness of his claim that [illegible] the most sceptical were forthwith convinced.

THE TRANSMISSION OF CANCER BY GRAFTING AND DIRECT INOCULATION.

Some of the results of grafting and direct inoculation have often been evoked in support of the microbic theories of cancer genesis, though upon very inadequate grounds. For more than a century experiments have been resorted to with the object of testing: (1) whether cancer can be transmitted from man to animals, or from one animal to another of a different species; (2) whether cancer is communicable from man to man, or from one animal to another of the same species; and (3) whether one part of a cancerous individual can be inoculated from another part which itself is the seat of cancer. Clinical observations have also been directed to [illegible] of these questions.

[illegible] made to Cazin[3] for the earlier, and to [illegible] "Cancer à deux," delivered before the Berlin Cancer Committee on April 3rd, 1901, for the most recent information on the second of these questions Macewen in his speech at the Glasgow debate and De Bovis in a recent article in *La Semaine Médicale*[4] have also quoted several cases of the alleged communication of carcinoma from man to man; and my friend and former house surgeon, Mr. W. G. Nash of Bedford, has collected five cases of supposed communication of cancer of the tongue and lip from man to man. Morau's observations seem to prove that cancer was communicated from mice to mice by means of bugs.

Many of the cases in man were instances of what is called "conjugal cancer"; and in these, as well as in the cases other than of the genital organs, the cancer was doubtless excited by chronic or repeated irritation and not communicated by the transmission from one person to the other of the carcinoma cells.

Several instances of auto-inoculation were quoted by the speakers in the London and Glasgow debates.

Hahn succeeded in grafting carcinoma and Cornil sarcoma from one part of a human being with incurable disease to another part of the same patient's body. Some experiments by Morau are of great importance, because they were the first which were made in a systematic manner to show the transmissibility of a malignant new growth from one animal to another of the same species.[5] Quite recently Jensen and Borrel have had successful series of inoculations and graftings in white mice.[6] Jensen[7] had a series of eight and Borrel of six successes.

None of the results of the experiments and none of the clinical cases just alluded to, however, give satisfactory support to the microbic theories; nor do they explain the specific capacity of the cells which enables them to grow and to multiply on new soil.

In the instances in which carcinoma has been developed the results have been due to the irritation excited by the tissue grafting, or to [illegible] implantation of the carcinomatous cells, and not to [illegible] ism. [illegible] bold [illegible]

The tumour products of microbic infection are [illegible] called granulomata formed out of the corpuscular elements of the blood, and the proliferation products of pre existing tissue; they are the results of a chronic inflammatory process, and all the tumours caused by the same kind of microbe are structurally the same, no matter in what part or organ they originate or develop. Not so the tumours of carcinoma and sarcoma. In endothelioma and spindle-celled sarcoma the cells of the secondary tumours are, as in carcinoma, histologically identical with the cells of the primary neoplasm. It is only in round-celled sarcoma that we cannot be sure whether the cells of the secondary growths are derived from the cells of the primary tumour or from the tissue in which the secondary growths occur. The round-celled sarcoma more closely resembles the chronic inflammatory processes than does spindle-celled sarcoma, and still more so than does carcinoma.

The primary tumour of carcinoma varies in structure according to its location and to the type of epithelial cell which is normal to the part affected. The secondary tumours are also composed of epithelium which has the same form and the same arrangement as that of the primary tumour; and the secondary tumours have, moreover, all the same delicacy of construction as to stroma, blood-vessels, and lymphatics, as well as other points of similarity with the primary tumour. All this was strikingly, if quaintly, put by Moxon at the London cancer debate when he remarked, "You find that rectum cancer is rectum tissue ...... whose structure is that of the Lieberkuhn follicles of the mucous membrane of the gut"; and as to the metastatic growths you do not "find rectum cancer in the rectum and liver cancer in the liver. But instead of that I have repeatedly seen rectum in the liver." Coats in the Glasgow debate told how the delicate structure of the blood-vessels which had led to fatal hæmorrhage from a primary growth was repeated in the secondary growths in the form of extensive extravasations of blood throughout the tumours. Stewart has recorded a case in which growths in the liver and lung secondary to carcinoma of the pancreas, besides having the racemous glandular structure of the primary tumour of the pancreas, had also a chemical resemblance, for upon analysis the secondary growths were proved to contain a high percentage of trypsin.

The definite establishment of these facts has proved that the secondary growths are produced by the migration of cells from the primary seat; that the development of these growths is solely by the multiplication of their own cells, and that there is no transition of the parenchyma of the part invaded into the tissue of the carcinoma. So with reference to sarcoma. The typical sarcomatous tumour element is the connective tissue cell and the secondary tumours resemble the primary in every respect.

[illegible] existing connective tissue [illegible] later removed and [illegible] What look like [illegible] every other theory which predicates that carcinomatous new growths are produced from anything else than epithelial cells, or that they are the result of changes in the pre existing mature cells, of the part or organ affected. Rindfleisch's theory, adopted also by Gussenbauer, while it grants the epithelial origin of the carcinomatous cells, attributes the local extension of the disease to a "spermatic influence" of these cells upon the adjacent connective tissue cells, as well as upon [illegible], and ascribes to them the power of con- [illegible] cells into epithelial elements. [illegible] that carcinomatous cells are derived from [illegible] hat carcinomatous tumours are primarily connective tissue growths. Other theories attribute the *original focus* and the local extension to retrograde changes in mature cells, either as the result of "over nutrition of the cells" (Maylard) or of atrophy and "reversion to their ancestral type from being worsted in the struggle for existence" (Woods Hutchinson), or of senile decay (Thiersch), or of inflammation, chronic irritation, or injury. Nor is the theory of Loeb that the penetration and migration powers of carcinoma are due to the dissolving effect of some ferment, probably allied to trypsin and secreted by the cancer cells, at all necessary to explain the general pathological anatomy of either carcinoma, endothelioma, or sarcoma. Considering the inherent capacity of a cancer cell (as of every primitive cell) for rapid breeding and self-maintenance, for abundantly proliferating in any part of the body to which it migrates, the wonder is that cancer is not readily transmissible from one subject to another. Instead of that, transplantation and direct inoculation of cancer from man to animals or from animals to animals have hitherto almost invariably failed. But had it been otherwise the success would not in itself have furnished the slightest proof that cancer genesis is due to a microbe; unless Koch's postulates had been complied with. In the successful transplantations and inoculations quoted by Cazin none of the experiments were controlled by trying if the resulting tumours could be reproduced in series in fresh experimental animals. Even in more recent experiments, with the exception of the few instances referred to above, this requirement has not been fulfilled.

[5] Morau: Archives de Médecine Expérimentale [illegible]

[6] Annales de l'Institut Pasteur, [illegible] 1903

[7] For still later report by Jensen see [illegible] June, 1903. Jensen's work extends over [illegible] concerns 19 generations.

From nothing that we know up to the present time of the action of micro-organisms can the microbic theory throw the least light upon the cases of alleged transplantation and direct inoculation of cancer from one person to another. How can we on the microbic theory explain a glandular-celled carcinoma producing in another person a squamous-celled carcinoma, or a squamous-celled carcinoma of the tongue giving rise to a spheroidal-celled carcinoma of the mamma or to a columnar-celled carcinoma of the stomach or rectum? Such alleged cases are at total variance with what occurs in auto-inoculation and with all the knowledge we have of the local, regional, and general infection of cancer, as well as with our experience of the action of microbes upon living tissues.

While transplantation and direct inoculation, as well as contagion, of cancer from person to person stand so far absolutely unproved, auto-inoculation, *on the other hand*, undoubtedly occurs and cases have been reported by de Morgan, Sir W. Jenner, and others. An ulcerated carcinoma frequently rubbed against or continually in contact with a cracked, excoriated, or abraded surface finds a favourable soil therein for the development of any of its cells which are deposited there. Sarcoma, in the same way, may be inoculated. *This occurred in a man, aged 62 years, under my care.* He had a mixed-celled sarcoma of a diverticulum of the bladder. On post-mortem examination this growth had caused a local infection, by direct implantation, with the result that a similar growth had formed on the opposite wall of the bladder. But in auto-inoculation just the same sort of process goes on as is witnessed in a lymphatic gland when the carcinoma cells have migrated to it from the primary tumour. It is simply "a metastasis of epithelial cells," as Klebs has described it.

Auto inoculation is strictly comparable to, if not identical with, the recognised mode of regional and metastatic infection of carcinoma and is as unlike microbic infection as those processes are admitted to be.

THE "TUMOUR GERM THEORY"—COHNHEIM'S THEORY.

There is one theory which is more consistent than any other with all that we know about malignant diseases, which fully explains the origin of very many non-malignant tumours, and is, I believe, destined to be accepted as the true explanation of the genesis of malignant new growths. It is the theory which was put forth by Durante of Rome about the year 1874 and a year or two later by Cohnheim (1877).

Thiersch, Ecker, Mayo, Lebert, Billroth, Klebs, Rindfleisch, and others had said that carcinoma is the result of the proliferation of [illegible] thus breaking away from the doctrine [illegible] Cornil and Ranvier, and others who [illegible] metaplastic products of the connective tissue.

Cohnheim went a step further and referred the origin of carcinoma to the proliferation not of mature but of *embryonic* epithelial cells. He taught that all tumours originate from a matrix of embryonic cells which during fœtal life are cut off from their proper connexions, remain in an undeveloped state, are surrounded by developing and ultimately developed tissues, and thus become, so to speak, "embryonic inclusions." According to Cohnheim these groups of cells, or "tumour germs," are portions of the germinal layers which, through not being utilised in the growth of the embryo, or by becoming displaced from their proper relations during the process of cell differentiation in the embryo, remain in a quiescent or latent state until excited into activity by one or other of several causes at some indefinite period after birth

Cohnheim insisted that a tumour never had its origin directly or indirectly from mature tissue. And herein lay the difference between Durante and Cohnheim, for whilst the latter regarded the matrix of embryonic cells or "tumour germ" as always of congenital origin, Durante thought that the elements from which arise all neoplasms, and especially the malignant, are either those "which have preserved in the adult organism their embryonic [illegible] characters, or which *have acquired them aga* [illegible] *weakening of their chemical and physiological* [illegible] Obviously Cohnheim's doctrine is insufficient b[illegible] explain the formation of malignant new growt[illegible] tissue, in immature callus, in unabsorbed inflammatory products, and in parts after injuries and operations of various kinds. This deficiency is met by extending the theory so as to include groups of cells which become isolated beyond their own natural boundaries by post-natal processes. Nicoladoni in 1881, in a paper on "Epithelioma in Sequestrated Wounds" ("*les plaies à séquestre*"), attributed the origin of these new growths to shreds of skin which had become displaced into fistulous tracks and had there proliferated under the stimulus of an accidental inflammation of the part or of an operation. Ribbert has indicated the possibility, during an inflammatory process, of a group of newly formed epithelial cells becoming completely detached from their natural parent tissue; and of the cell or cells so withdrawn from the control and growth-regulating influence of normally surrounding cells, assuming an exalted independence and power of proliferation whereby a tumour becomes developed. He also recognises that a *fragment* of sequestrated tissue detached by trauma of any sort may in the same way become a "tumour germ."

It was to meet this deficiency of the Cohnheim theory that Senn added to it this corollary: "The tumour matrix may be composed of embryonic cells, *the offspring of mature cells, which have failed to undergo transformation* into higher tissue, and which may remain in a latent, immature state for an indefinite period of time, to become under heredity or acquired exciting causes the essential starting point of a tumour." Senn expresses this extension of the "tumour germ" theory in his definition of a tumour thus: "A tumour is a localised increase of tissue, the product of tissue proliferation of embryonic cells of congenital or post-natal origin, produced independently of microbic cause" We thus see how Durante, Nicoladoni, Ribbert, and Senn embrace and supplement the incomplete theory of Cohnheim by recognising a post-natal origin of a cell matrix.

By these theories metamorphosed mature cells, as well as pathological microbes, are excluded as etiological factors in tumour *formation*, and a well-defined line marks off malignant and simple tumours alike from the inflammatory swellings, or granulomata, which are the products of the action of micro-organisms. If it can be proved that epithelial and connective tissue cells can be displaced as well as isolated, after birth as well as during the development of the embryo, we can understand how carcinoma may spring up not only in parts where epithelium normally exists but also as a primary growth in bones, lymphatic glands, or other mesoblastic structures and organs. *Primary* carcinoma may also take origin, in situations unusual *for* epithelial new growths, from a vestigial structure, a rest, or an accessory *organ*. [illegible] or post-natal But if all kinds of tumours arise from [illegible] matrices of embryonic tissue, what is it whi[illegible] matrix shall in one case develop into an innoc[illegible] malignant new growth? The answer is that the simple or malignant nature of the tumour depends partly on the stage of differentiation of the cells of the matrix at the time when they are arrested and isolated and part[illegible] so-called physiological resistanc[illegible] If the cell growth is arrested [illegible] differentiation and the resulting matrix consists of epithelial cells the tumour will be an adenoma or a papilloma; if the arrest of the development of the same cells takes place at an earlier stage the tumour would be a carcinoma. The same applies to sarcoma and the benign connective tissue tumours. The nature of the tumour thus depends upon the embryonic layer from which a matrix is derived and upon the stage of cell differentiation at the time when the cell growth is arrested.

I propose now to examine, as well as the time will permit, the evidence in favour of the separate parts of "the tumour germ theory"—namely, (1) the existence of congenital matrices of embryonic cells; (2) the existence of matrices of post-natal formation; (3) the continuance of these matrices for a time in a dormant state; and (4) the causes which arouse the matrices into activity.

1. What proof do we possess of the existence of congenital matrices of embryonic cells? It is hardly necessary to enumerate the many instances of "vestiges" and "fœtal

rests" which are found in the human body, as they now form a brief chapter in the latest text-books on anatomy. Tracts of embryonic epithelium are well known to occur in the tongue, gums, face, scalp, neck, brain, eye, testicle, broad ligament, ovary, and along the lines of coalescence *of the trunk.*

Many matrices are derived, we know, from portions of embryonic skin becoming buried in the mesoblast in the process of closure. According to Ebstein it is not uncommon to find in newly born infants isolated pearls of epithelial cells buried in the connective tissue by [illegible] the product [illegible] tissue or [illegible] connective [illegible] of the epi- [illegible] Matrices of [illegible] s for such tissue or in abnormal; when in abnormal the matrix is said to be "*misplaced.*" *Bodies identical in structure with the suprarenal* gland are found not only in connexion with the capsule, the cortex and the hilum of the kidney, and in the perinephric tissue, but also beneath the capsule of the liver, in the broad ligaments of a fœtal uterus, in the inguinal canal, and in some fatty tumours of the spermatic cord. That they have not more frequently been met with than is the case is probably due to the fact that they have not been looked for, and Bayard Holmes states that remnants of the adrenal [illegible] the genito-urinary tract in [illegible] n discovered in the renal [illegible] They probably represent [illegible] to come into relationship [illegible] yma. *The occurrence of* [illegible] ditional mammæ is by no [illegible] s of additional mammary [illegible] to 30 per cent.[8] *In many* [illegible] ed as thickened ridges of [illegible] groins. *Subsequently the* [illegible] ch of which is capable of [illegible] gh such embryonic ridges [illegible] embryo, yet it has been shown that al [illegible] tions of cutane [illegible] sebaceous glands.

Roux discovered isolated columns of cells in the inner embryonic layer of frogs' embryos; once he saw as many as 13.

For many other instances of vestigial and abnormal structures reference may be made to Professor Arthur Robinson's article in Morris's "Treatise on Anatomy." Dr. John Beard in a lecture on the Embryological Aspects and Etiology of Cancer[9] states that in elasmobranch fishes (and he implies that the same conditions exist in man) a considerable percentage of the primary germ cells fail to reach their normal position, *the germinal ridge; that many of* these vagrant germ cells degenerate and disappear, but all do not; and that the common situations for the origin of cancer are the very ones in which vagrant germ cells are usually met with.

2. The occurrence of matrices of embryonic tissue of post-natal origin is capable of completely satisfactory explanation. Leo Loeb[10] has described how in the healing of a superficial wound the epithelium of the skin on either side of the wound was seen to have fused itself into a cell mass which sent off branches not only across the wound but down into the blood clot and the connective tissue, especially if the connective tissue had been injured, and these branches of the cell mass even burrowed through cartilage. It is intelligible enough, therefore, how in the cicatrisation of ulcers and wounds generally some of the epithelial buds become "isolated," and being thus shut off *from* their proper anatomical relations and from their normal function may, under suitable stimulation, develop into carcinoma. Epithelial cells not utilised in the process of epidermisation and becoming buried in the scar tissue may when brought under the influence of the needful exciting cause give rise to carcinoma This sequestration of unused cells may occur during healing after burns, chronic ulcers, lupoid and syphilitic sores, fissures, sinuses, fistulæ, compound fractures, cracked lips, the excoriations from soot, tar, or paraffin, and after lacerations and ulcerations of the cervix uteri; also after the alternate *breaking down* and *healing in such diseases* as ichthyosis of the tongue, cheek, vulva, vagina, and after ulcers caused by carious teeth, as well as after wounds, whether operation wounds or otherwise.

In like manner a matrix may be produced from which sarcoma may arise. In parts which have been the seat of chronic inflammation and in scars, unspecialised connective tissue cells may be buried, and will be there ready to grow into a sarcoma under the influence of a sufficient exciting cause. Some of the embryonic cells during the process of repair of a fracture may fail to attain to the perfection of their parent cells and will thus remain in the part in a latent condition, like the congenital matrix of embryonic cells predicated by the original theory of Cohnheim.

3. What proof have we that a matrix of embryonic tissue, whether of congenital or post-natal origin, can remain for a length of time in a quiescent state and then suddenly start *into active growth under the inflence of some stimulus?* This is actually witnessed in the growth and development of the teeth, the bones, the skin and its appendages, the larynx, the mammæ, and the organs of generation, the cells of which remain for years in a state of incomplete differentiation and then normally, under the physiological stimulus which occurs at puberty, take on rapid proliferation. Pathologically the same suddenly aroused activity is seen in certain epithelial tumours which are rarely noticed before puberty, such as dermoids, branchial cysts, and mammary adenomata. Rudimentary organs and accessory organs which hitherto as to growth had been stationary as well as functionless become the starting points of tumours, more especially at and after puberty.

Puberty is the time of life characterised by the highest degree of tissue activity, and it is at this time that a matrix of embryonic cells *is prone to* [illegible] a tumour [illegible] with the ca [illegible] adequate [illegible]

Vestiges and rests lie dormant for years, often throughout life; but they are "tumour germs" all the same which under suitable conditions would undergo active cell proliferation and rapidly develop into tumours. *The same latency, followed by activity of growth, is seen* in those excesses of embryonic tissue which give rise to local or general hypertrophies or giant growths; the excess of the embryonic tissue is present at birth, though it may not take on activity until comparatively late in the life of the individual.

4. The causes which arouse a matrix into activity are numerous. For a matrix of embryonic cells to be transformed into a tumour it must be aroused into activity by some exciting agent. We must now inquire what these exciting agents are and in what relation the commonly ascribed causes of cancer stand to the "matrix" or "tumour germ" theory. The stimuli which arouse the cells of the dormant matrix to active proliferation are either general or local, congenital or acquired, and the chief amongst them are the alleged common causes of cancer. Let us consider four of them in some detail—namely, heredity, age, traumatism, and chronic irritation.

(*a*) *Heredity.*—A case like that of Friedreich, where a woman with carcinoma gave birth to a child affected with carcinoma, is altogether exceptional.

In a case in which I performed Cæsarean section on account of [illegible] uteri and the vagina, both [illegible] *apparently quite healthy.* [illegible] later, the child being still [illegible] lost sight of. There are possibly not a few of such cases and it would be well if in future the lives of these children could be followed.

Statistics hitherto have given insufficient and inaccurate information concerning *the frequency with which the off*spring of parents carcinomatous at the moment of conception or delivery have been affected with carcinoma. There is, however, no more reason to doubt that an aptitude is transmitted from parent to child for the development of carcinoma and sarcoma than for denying an hereditary disposition to various other diseases. This aptitude, or predisposition to malignant disease, has been appropriately described as "a diminution of the physiological resistance of the tissues" which permits of their being invaded and destroyed by the proliferating cells of the tumour matrix. In the great majority of cases (in Cohnheim's view in *all* cases) the matrix itself is of congenital origin, but though congenital, it may never be excited into activity. In others, the matrix is of post-natal origin, and if the necessary stimulus arises and the tissue resistance is weak cancer will occur, *even in persons* in whose family cancer had hitherto been absent.

In a sense, then, all tumours are congenital or hereditary, except such as are derived from a post-natal matrix, and even in these cases [illegible] iological resistance [illegible] at least of those [illegible] *enital or acquired.* [illegible] ed, not inherited.

---

[8] A. Robinson: Morris's Anatomy, third edition.

[9] THE LANCET, June 21st, 1902, p. 1760.

[10] Johns Hopkins Bulletin, January, 1898

If it be granted that there is a family tendency to vestiges, rests, or matrices of embryonic cells it is at once intelligible how such an hereditariness may lead to mammary carcinoma in one member, uterine carcinoma in another, squamous-celled carcinoma in another, and sarcoma in a fourth member of the same family.

(*b*) *Age.*—Carcinoma is admittedly a disease of middle-aged and elderly persons and of senile tissues or organs like the uterus and breast after the child-bearing age. But on the "tumour germ" theory there is no difficulty in explaining the occasional occurrence of carcinoma in very early life or at any period of life if the physiological resistance is especially weak in the individual and the matrix irritant or exciting cause is very considerable. Sarcoma occurs in much younger life than carcinoma and is most frequent in children and young adults, but no age is exempt from it.

There may be in the same person several congenital matrices, one or more of which may be of the epithelial type, one or more of the connective-tissue kind. During childhood and young adult life the exciting cause, or matrix stimulus, will start into activity a connective-tissue "tumour germ," but during mature life and in advanced age the same stimulus will arouse by preference a matrix of embryonic epithelial cells because the epithelium is more active and vigorous than the connective tissue at the later periods of life.

Assuming the presence of a matrix of each kind in the same individual and that middle life has been reached without the occurrence of any matrix-arousing stimulus but that after this period some *general* exciting cause comes into existence, the matrix of epithelial cells will most likely be the one to respond and a carcinoma, not a sarcoma, will result; but there may be the simultaneous appearance of different kinds of tumours. Should the stimulus be a *local*, not a general one, the matrix upon which alone it acts will be aroused and a carcinoma or a sarcoma will be developed according to the type of cells forming the matrix which is stimulated.

With advancing age, or senility of tissue, come impaired vitality and lessened power to resist the effects of injury, hence the diminution of the physiological resistance of the tissues and the increased proneness to the formation of cancer. Little is known, it must be admitted, of what this "physiological resistance" really consists; what this power is which holds in check altogether, or for a long time, the proliferating tendency or force of a tumour matrix, as it does for years the growth and development of the mammary glands, the organs of generation, the larynx, the teeth, and the beard. The existence of such a force was, however, demonstrated by Cohnheim and Maas who introduced pieces of young periosteum into the jugular veins of animals. The periosteum produced bone which was always limited in size to the lumen of the vessel in which the periosteum embolus became impacted; the bone never extended beyond the vessel walls, a physiological resistance restricted it, no further growth ensued, and in time the ossified periosteal graft was absorbed. The same investigators showed that transplanted grafts of embryonal tissue succeed, whereas grafts of mature tissue are invariably removed by absorption in a short time. Embryonic tissue—fœtal cartilage, for example—taken from animals before they are born and engrafted into rabbits proliferated abundantly; grafts from benign tumours only grew to a very limited extent, if at all, and were then removed by absorption. Grafts of malignant tumours have almost, without exception, failed, though composed as they are of embryonic tissues. This seems to show that the physiological resistance to malignant cell proliferation is, happily, more effective than against fœtal embryonic tissues or against the embryonic tissue of benign tumours. The weakness or want of this physiological resistance, besides being sometimes inherited and often a consequence of age, can be acquired through injury, irritation, inflammation, and other pathological, general or local, causes.

(*c*) *Traumatism* is often said to cause malignant disease just as it used to be said to cause inflammation and suppuration. But just as no amount of injury will of itself excite suppuration without the presence of pathogenic and pyogenic organisms in the injured tissues, so no amount of injury will give rise to a tumour without the presence of a matrix of embryonic tissue of either congenital or post-natal origin. No so-called exciting cause will produce cancer or sarcoma in the absence of the "tumour germ" of epithelial cells or connective-tissue cells respectively. But given the presence of such a matrix then injury of any kind, irritation of any kind—mechanical, chemical, thermal, or microbic—may excite cancer formation both by arousing the matrix into activity and by diminishing the physiological resistance of the surrounding or adjacent tissues. Whether the cancer follows the injury quickly or tardily depends upon the intensity of its effects upon the matrix, or upon the degree to which the physiological resistance or, what is probably the same thing, the nutrition is affected, or upon both these conditions.

(*d*) *Prolonged irritation and inflammation* may (1) excite a matrix of congenital tissue to proliferate; (2) may diminish physiological resistance of the tissues around it; or (3) may provide a post-natal matrix of embryonic epithelial or connective-tissue cells and thus originate the essential factor of malignant disease as well as stimulate it into proliferative activity. Carcinoma of the breast following eczema of the nipple is an instance of malignant disease aroused by chronic irritation and inflammation. Epithelioma of the tongue following long standing ichthyosis of that organ is another. They are typical illustrations of agents which act in each of the three ways just mentioned. Yet that neither of these pathological irritants is of itself the true and essential cause of carcinoma is proved by cases in my own practice. In 1880 I published two of the earliest reported cases of chronic eczema of the nipple (Paget's disease). Out of 305 cases of mammary diseases which up to that time I had seen in my hospital cancer out-patient practice, eczema of the nipple was met with in eight cases, in six of which there was no cancer present in the mamma. In only two cases then out of eight did carcinoma of the breast follow the chronic eczema of the nipple and areola. It is certain, therefore, that something more than the long-standing irritation of chronic eczema is needful for the development of mammary cancer, and this something is a "tumour matrix" in the breast. If due to irritation alone, why did not carcinoma occur in all the eight cases equally?

If during a stage of cicatrisation of part of the eczematous area a local post-natal matrix had formed, the carcinoma, beginning as it might then have done in the skin, would have been a true squamous-celled epithelioma, not a glandular carcinoma. In one of these two cases there was a wart in close proximity to the eczematous areola, but though a wart is apt in certain circumstances to become an epithelioma, it was the breast, not the wart, we must assume, which contained the tumour matrix most readily provoked into riotous epithelial proliferation. It can hardly be maintained that the carcinoma was due to the prolonged irritation of the eczema upon a breast in which the senility of the organ had very specially diminished physiological resistance (or the "tissue tension") of the part, because one of the women referred to was hardly 30 years old and the other was only just 40 years of age.

Ichthyosis of the mucous membrane affords similar proof against the sufficiency of chronic irritation *per se* to excite carcinoma. In 1883 I published a paper on Ichthyosis and Epithelioma of the Tongue. In 13 out of 36 cases of epithelioma of the tongue ichthyosis of the tongue had been a precursor of the carcinoma. In 11 cases of ichthyosis of the tongue and three cases of ichthyosis of the buccal and labial mucous membrane (14 in all) carcinoma *did not* occur. The inference from these cases also is that in the 13 cases in which carcinoma supervened there was in the corium, or submucous structures, a matrix of embryonic epithelial cells which was stimulated into malignant growth by the long-standing ichthyosis. In the 14 cases in which carcinoma did not supervene the presumption is either that there was no matrix, or that the exciting cause was inadequate to arouse the matrix into activity, or that the physiological resistance of the surrounding tissue was sufficient to prevent its growth.

If it be granted that for cancer to form a matrix must exist and that without such [illegible] however prolonged, can cause the formation of a [illegible] ve can at once explain how it is that a carcino [illegible] mate near a lupoid or syphilitic sore not in it, near an ichthyotic patch not in it, near an ulcerated nipple and areola not in them. A tumour matrix within the limits of an inflammation receives an increased blood-supply and this of itself is an incitement to active cell pr[illegible] has shown by experiments that inflammation [illegible] so that persons born with, or acq[illegible] are more likely to become the s[illegible] adjacent structures become the seat of inflammation [illegible] the consequent loss whereas without [illegible] the tumour matrix of power of resist[illegible] undoubtedly attacks might remain lat[illegible] longed and repeated parts and organs [illegible] irritation.

It is unnecessary to dwell on the several other alleged causative factors of canc[illegible] mental worry, and so on can [illegible] more than secondary or s[illegible] timulating a pre-existing [illegible] sistance of the structures, [illegible] or of doing either we do not know and we must await the compilation of more accurate statistics than have hitherto been made.

5. The validity of the premisses of the "tumour germ" or "matrix" theory being assured, let us see whether the conclusion to which the theory leads can be established by actual facts. This conclusion is that cancerous as well as benign tumours spring from "inclusion masses"—some of which are "displaced" masses—of embryonic cells either of congenital or post-natal origin. A large variety of benign tumours which are well known to arise from congenital matrices might be quoted.

[illegible] supplied.

(a) We now know that accessory spleens, accessory ovaries, accessory thyroids, accessory suprarenals, accessory mammæ and outlying portions of the mammary gland, and remains of the Wolffian body are all responsible for tumour formations. All that is known of teratomata—endogenous and exogenous—lends support to the Cohnheim theory. All endogenous teratomata or teratoid tumours, including branchial cysts, and the simplest as well as the most complex forms of dermoids, undoubtedly arise from congenital embryonic matrices. Skin dermoids are the most frequent form of fœtal inclusions and consist of portions of embryonal skin isolated and buried in mesoblastic tissues; dermoids which contain mucous membrane are derived from a matrix of hypoblastic origin; whilst dermoids with complicated contents, such as bone, cartilage, and portions of organs, can originate only from a displaced matrix representing different tissues and organs. Or, conversely stated, [illegible] cysts are derived from the remnants of branchial clefts and these remnants, like the "inclusion" matrices of dermoids, may remain [illegible] growth [illegible] nces at [illegible] y some [illegible] s of the [illegible] certain [illegible] and also remains of the Wolffian body, are the source of origin of certain paranephric tumours. Grawitz traced tumours of the kidney to islets of separated and displaced renal tissue. Outlying portions of the mamm[illegible] occasi[illegible] gland[illegible] now a[illegible] is it [illegible] occur [illegible] they [illegible] present held that such sequestrated and encapsuled portions of the glands are the source of fibro adenomata, adenomata and small cystic tumours found in the liver, parotid, kidney, and other organs, as well as in the mammary glands.

By far the larger number of cartilaginous tumours appear near the epiphysial lines of the long bones where it is common for islands of embryonal cartilage to persist embedded in the bone tissue. Odontomes are believed to be due to misplaced and isolated buds or islands of embryonic tissue The vast majority of angeiomata and lymphangeiomata are now regarded as survivals of the embryonic vascular and lymphatic structures respectively and, as such, unquestionably [illegible]

[illegible] of the ovary, according to Waldeyer and [illegible] the majority of cases starts from an embryonic tubular matrix of Pflüger's [illegible]

[illegible] which are in reality adenomyomata—true tumours [illegible] partly of glandular but in greater part of muscular tissue—are [illegible]

(b) There is no lack of evidence, either, that tumours are formed from matrices of post-natal origin. We know that tumour germs arise as the outcome of surface epithelium, hair follicles, or portions of skin forced into the deeper tissues by punctured and other wounds. From such sequestrated fragments of tissue "implantation cysts" are formed—a group of small tumours allied in character to the sequestration dermoids derived from matrices of congenital origin. These "im- [illegible] material. Cysts of the iris following mechanical injury have been found to contain sebaceous matter and in one recorded case an eyelash. Cysts lined with layers of cells like those on the anterior surface of the conjunctiva have been known to form in the cornea after gunshot and other accidental wounds, as well as after operations for cataract, and are almost certainly derived from conjunctival epithelium forced into the deeper layers of the cornea.

[illegible] formed during the repair of wounds.

(c) It has been unquestionably proved that the "tumour germ" theory correctly accounts for the origin of many varieties of benign solid tumours and of dermoids and other cystic tumours, and we must now try to answer the question with which we are especially concerned: Does it not afford the true explanation of the etiology of malignant tumours also? In attempting to reply to this question it may first be pointed out that regions and organs in which embryonal inclusions are specially likely to occur are also common situations of primary malignant diseases. To realise the truth of this statement we have but to recall the frequency of sarcoma near the ends of long bones, the occurrence of myeloid and periosteal sarcoma and epithelioma in the mandible and upper jaw, of carcinoma of the uterus, œsophagus, stomach and rectum, and tongue and mouth. In the lip the commonest seat of origin of carcinoma is along the line of junction of the skin and mucous membrane. In the rectum the parts at or near the junction of the skin and mucous membrane, and those near the union of the proctodæum (cloaca) and the hind gut, are the *areas of the* greatest liability to carcinoma. In the stomach the pylorus and its immediate region are the chief seats of carcinoma, and it is here, as Cohnheim has pointed out, that the anatomical structure of the organ varies most; it is here also that there is the greatest liability to pathological changes and thus to the development of post-natal as well as of congenital matrices. Such anatomical areas as those just mentioned, like the cervix uteri, are zones of transitional epithelium and are provided with glands not always of normal functional perfection; in these so-called "cancer belts" we may expectantly look for "tumour germs" *in the form* of isolated congenital nests of embryonic cells.

In a thesis for the Doctorate of Toulouse in 1902 Guillaume Cargue has written on the occurrence of epithelioma in the old sites of osteomyelitis. Cargue quotes 44 *cases* collected from literature, together with five cases observed in the clinic of Professor Jeannel of Toulouse. In all these cases epithelioma of the bones was due to fragments of skin which became invaginated or to detached epidermis cells which became implanted in the bones. The carcinoma appeared either in a *diffuse form* or completely inclosed in the tissue of the bone. Cargue refers to other cases of primary epithelioma of bones after fractures and in connexion with necrosis. *He also quotes from* a communication on "Tumours of Bone" made to the Congress of Surgery in 1899 by Polosson and Bérard of Lyons to the effect that epithelioma *occurring* in the maxilla is always due to the proliferation of epithelial cells of the mucous membrane which have become included in the bones with the *dental* germs. *He refers* also to Nicoladoni's work on the formation of epitheliomata in sequestration wounds. Several observers are mentioned by Cargue as having contributed to medical literature cases of epithelioma which have developed in old scars, ulcers, *callosities*, fistulæ, and such like affections of the soft parts, and he concludes that the paucity of these and of similar recorded cases of primary epitheliomata in connexion with bones is due to surgeons not having recognised the real nature of the disease or of having failed to ascertain the actual seat of it.

Various *forms* of malignant tumours of the kidney are attributed to fœtal rests, such as adrenal inclusions and aberrant renal tubules, embedded in the capsule of the kidney and capable of being stimulated into epithelioma. Dr. Charles Creighton has described malignant tumours as arising in and near the mammæ, and in the axillæ from certain sweat glands situated under the skin, not usually in it, but between it and the axillary fascia. These sweat glands sometimes occur also along the lateral and anterior regions of the chest and as appendages of the milk sinuses scattered through the mammæ. They must be regarded as survivals or rudimentary organs, and as being subject to all the risks of such survivals or rudiments. Dr. Creighton also describes coiled tubular glands and a rudimentary mammary lobule consisting of a branched tube without real acini as being the starting points of carcinoma within the mammary gland, and he considers that the proper mammary structure takes really no part in the morbid growths of the organ. Volkmann described deep-seated primary carcinoma originating in the neck from the branchial clefts under the name of "carcinoma brancheogenes," and Guttmann refers to similar cases starting from accessory thyroids as "struma carcinomatosa accessoria." In the cases of multiple tumours in bones of the nature of thyroid tissue recorded by myself and others the conclusion was irresistible that the tumours were metastases from accessory thyroids or from matrices or "inclusions" within the substance of the thyroid gland itself. It is doubtless due to the fact that in these cases, as in some instances of carcinoma, the metastatic growths so far exceeded in size and conspicuousness the primary tumour that the nodule in the thyroid gland from which the tumour cells had migrated has been overlooked. I am indebted to Dr. E. F. Bashford for the details of a case recently published by von Oderfeld and Steinhaus which is a strong confirmation of this opinion. A nodule slightly differing from the normal thyroid tissue and surrounded by a connective-tissue capsule was found in the right lobe of the thyroid of a female, forming a primary tumour from which metastases in the cranial bones, the clavicle, and the sternum were derived. The pernicious growth of the chorion, known as deciduoma malignum, which occurs in the human uterus when the embryo is aborted or dies before the asexual generation has been suppressed, was pointed out by Marchand in 1895 to be of a carcinomatous character, and is quoted by Beard as affording "the key to the problem of the nature of cancer," and as making the cause of cancer "clear as the light of day."[11]

The remnant of ovarian tissue occasionally left behind after an ovariotomy may become pathologically active, serve as a post-natal matrix, and develop into malignant disease. Roger Williams[12] attributes the extraordinary frequency of malignant disease which follows the removal of one or both ovaries, and which in Spencer Wells's experience amounted to 36 per cent. of the known causes of death of those who had recovered from the operation, to the excessive formative activity aroused after the operation in the aberrant accessory ovarian structures which are so frequently present in the broad ligament and its vicinity.

Primary carcinoma originating in a situation where no epithelium normally exists sometimes springs from a previously undetected dermoid cyst or dermoid-cyst matrix. A displaced matrix of epithelial cells isolated from its own blastodermic tissue and buried in the mesoblast, if it becomes a tumour, will develop into one of an epithelial character. Tumour cells, like normal cells, always breed true. Connective-tissue cells cannot produce epithelial cells, and epithelial cells invariably produce their own kind and no other. Virchow when he met with a primary carcinoma in the tibia, not recognising this physiological law, believed the cells of the carcinoma were produced from the connective tissue at the spot where he found them and called them epithelioid. The knowledge of this law as applied to a carcinoma developed from a displaced or misplaced epiblastic matrix which has been roused into proliferative activity by some exciting agent corrects such a histological error and explains the occurrence of the heteroplastic tumour. It also explains how an "endothelioma," which resembles carcinoma in its characters, is developed as a primary new growth in serous membranes and lymphatic glands—structures which are of mesoblastic origin and in which, therefore, no epithelium normally exists; it likewise explains how a glioma, which in its anatomical and clinical characters is a sarcoma, can occur in the brain or retina which are derived from the epiblast.

6. We must next inquire whether the "tumour germ" theory can account for the transformation of a benign into a malignant new growth. We need not stop to inquire what evidence there is that this transformation ever takes place. The fact of its doing so is no longer, as formerly it was, disputed. Warts, moles, dermoids, fibromata of the skin, uterine myomata, and papillomata in various situations might be quoted in proof of benign tumours passing into malignant.

The change to malignancy may originate in a matrix of tissue derived from the organ or part affected and which has become sequestrated and inclosed within the structure of the benign tumour during the process of the growth of the tumour. Or in the process of its growth some of the daughter cells within the benign tumour itself may fail to attain the degree of differentiation of the parent cells and may subsequently develop on their own account into a malignant neoplasm. A woman under my care some years ago was the subject of an intramural uterine fibro-myoma which became the seat of colloid carcinoma. The case was published by Mr. W. Roger Williams[13] who mentions that a few cases of carcinoma originating in uterine fibroids had been recorded by Virchow and others. It is probable that in my case the carcinoma, which was clearly glandular, was developed from the deep extremity of one of the utricular glands sequestrated in the process of the growth of the fibro-myoma and which thus came to form an epithelial tumour germ—just as glandular elements have been observed in the analogous new growths of the prostate.

OTHER EVIDENCE IN FAVOUR OF THE "TUMOUR GERM" THEORY.

A. The matrix theory escapes equally the objections raised against the local and the constitutional theories of cancer.

We have only to suppose the presence in the same person of two or more matrices, or "tumour germs," of which there are many instances, and to bear in mind that these matrices are generally of congenital origin, and that other causes besides senility can both arouse into activity the cells of a matrix and weaken physiological resistance of the adjacent tissues, to dispose of the following chief objections to the local doctrine: (1) that malignant tumours occasionally occur simultaneously on the two sides of the body; (2) that malignant disease if it were really local ought to be completely cured by early and free excision; (3) that malignant disease frequently attacks several members of the same family; and (4) that carcinoma occurs in its most virulent forms in very early life before the tissues have become debilitat[illegible]

Again, [illegible] an exciting cause is necessary to arouse [illegible] to active cell proliferation, and that in th[illegible] stimulus the "tumour germ" will continue quiescent throughout life, the following objections against heredity are easily answered: (1) cancer, as a rule, shows no sign of development in the parent until after the birth of the offspring; (2) that it is not in accordance with the laws of heredity that a disease which, as a rule, does not show itself in the parent till long after the birth of the progeny should manifest itself in the progeny; and (3) that cancer is often seen in the offspring of parents who are still living and free from any cancerous disease.

Such objections as these to the constitutional theory are in reality rather quibbles than arguments. As to the third, I may here remark that I have known several instances of parents, themselves in good health at the time, losing a child from carcinoma, but subsequently one or other of them has likewise died from the disease. And as showing a ge[illegible] ritance of "tumour germs" we must all hav[illegible] lipoma, nævus, fibro-adenoma, dermoid, and [illegible] in the children of parents who have died from cancer or in parents who have lost a child or children from cancer.

B. The matrix theory enables us to understand the long intervals which occur after removal of cancer by operation before recurrence takes place, for just as the "tumour germ" of the primary growth remained for years unaroused, so a single cell or a few cells migrated to a lymph gland or duct or into the areolar tissue some distance away may continue quiescent owing to the efficiency of the physiological resistance of the surrounding tissue. The cell or cells are the "tumour germ" of the recurrent growth as the original matrix was of the primary, and are subject to the same kind of restraint and respond to the same kind of stimuli.

C. The "tumour germ" theory also explains the so-called recurrences, after either short or very long intervals, in parts or organs away from the original site and out of the line of direct lymphatic infection. It explains, too, the development in the same person of two malignant tumours of different blastodermic sources and of their existing simultaneously, or of one occurring after the other has been excised.

I will quote two instances in which the very early removal of a primary growth and the wide extent of its removal and the many years of freedom from any fresh outbreak of disease seem to make the idea of ordinary recurrence more than improbable. Two ladies of about

D. Lastly, the "tumour germ" theory affords a better explanation of the local extension of carcinoma than any other which has been put forward. It ascribes it to cell *proliferation of the margins of the matrix; the growth of* the tumour to the multiplication of the matrix cells, not to the "reversion" or conversion of the pre-existing mature epithelium into tumour tissue.

These cells penetrate *deeply beyond the basement membrane into*

The foregoing are some of the reasons for regarding the "tumour germ" theory as the most, indeed in my opinion as the only, probably correct theory of cancer origin which has ever been put forward—as the only hypothesis which is consistent with all the known facts of cancer. Hitherto, what would seem to be the strongest evidence against the "*tumour germ*" theory is that which seems the strongest evidence in favour of the microbic theory—namely, the successful serial experiments upon mice with cancer tumour tissue which were carried out by Moran in 1893 and have been recently repeated by Jensen and Borrel But Borrel admits that his successful series was only obtained by treating at each "*passage*" a number of mice, varying from 12 to 15 This is of much importance, because many mice were found to be unaffected. The proportion of successes to the total number of animals experimented upon at each "*passage*" in the series ought to be given by each experimenter. The tendency to the development of cancer in mice would seem to be strong, judging from what is stated in Borrel's paper as to the frequency of cancer in certain caged mice not operated upon.

Up to the present time the microbic theory has not advanced our knowledge of the cause of cancer one iota in spite of all the talent and skill which have been employed upon it, whereas every year facts in support of the "tumour germ theory" are discovered almost without being sought for. Excepting for these aforesaid recently discovered facts our knowledge of the causation and nature of cancer would be no greater now than it was 30 years ago; indeed, the very facts about cancer which were recognised and established a generation ago are to day the strongest *a priori* arguments against the microbic origin of cancerous diseases. The truth is that for the last 10 or 15 years cancer research has been too exclusively directed to microbes and too little to cancer. The attention given to cancer research by many able workers has been too restricted to the search for the problematical "cancer organism" to allow of much thought being directed to the other factors in cancer. The "high power" lens and the fine adjustment—so to speak—have put into the background for the time being the binocular field-glass with its adaptability for focussing the various features of an extensive perspective It is, however, well that all these bacteriological observations and experiments have been made; indeed, others are still necessary if only to clear up certain difficulties respecting the nature of the so called "cancer bodies" and how they come to be present in the cancer cells. But what is wanted, also, is that some equally skilled research work should be directed to other questions—embryological, morphological, chemical, and functional—to such subjects, for example, as those to which Marshall drew attention *in his suggestive Morton* lecture, namely, the chemistry of cancer tissue, the structure and changes in the stroma, the minute anatomical relation of nerves to the cancer cells, and of the effect of the loss of control of the nerves over them. We want more information respecting the state of the arteries in cancerous new growths.

Thiersch called attention to degenerative changes in the arteries in cancer and Senn states that proliferative endarteritis was found as a rather *frequent accompaniment of carcinoma* where there was no indication of the coexistence of the same condition of the arteries in any other part of the body.

The arterial changes in cancer tumours have not so far been sufficiently studied. They may, however, prove to be of importance in connexion with treatment, with the clinical effects and histological results of the x rays upon cancer, and also in relation to the rate of growth and to the tendency to metastasis, to the various degenerations, and to ulceration and sloughing of cancerous tumours.

All questions of this kind possibly might be worked out in private or hospital laboratories, but there are numerous other important questions to be answered, *e.g.*, as to the agencies which excite into action the invariable and unconditional cause of cancer. These never yet have been properly investigated and they can only be so by some organised scheme such as that which has recently been undertaken by the two Royal Colleges. Questions as to the geographical and racial distribution of cancer, of climate, soil, articles of diet, occupations, cancer houses, and many others, can only be settled after statistical and other investigations have been made *and checked and cross checked, controlled* and *re-controlled* by each other. Such investigations are beyond the means and powers of individual science workers or of medical institutions; they need to be undertaken by an organised body with relays of workers and sufficient funds at its command to provide for the uninterrupted pursuit of the inquiries

Katz of Hamburg, whom I have previously quoted, remarked "it is to be deplored that Cohnheim's *doctrine has so long found an extended acceptance, for the further* development of cancer research would have, *through it, no* value A standstill would result from the fatalism which underlies this theory. The *same may be said with regard to* Ribbert's theory, which, though of far later date than Cohnheim's, is in pursuit *and continuation of it.*" But a theory if it has the evidence of truth must be minutely and impartially examined, even though it seems to lead to a conclusion which we might wish to escape. There is, however, no occasion for so pessimistic a view as that of Katz. The "tumour germ" theory, at least does this; it convinces us of the local origin of cancer and of the positive curability of it if removed quite early and completely. Of course, it does not guarantee one against the *formation* of another malignant new growth any more than the repair of a broken bone guarantees one against the occurrence of another *fracture.* It should also encourage the early and more frequent removal even of benign growths Future researches may *reveal a method whereby a special inhibitory* influence *may* be brought to bear upon the cells of the "tumour matrix" on the lines tried by Foulerton, or a restraining, *even a strangulating,* effect upon the tumour cells by the tumour matrix may be produced, as suggested by *Marshall. But in any* case we can reasonably hope and expect that the organised researches now commenced by the Royal Colleges will in time yield much information as to how to prevent cancer by teaching us what are the real agencies *which stimulate it into existence.*

In bringing these remarks to a conclusion I will borrow the *description recently* given by Mrs. Crawford of the mind *of the late* M Thiers and apply it to the theory founded by Durante and Cohnheim. "It has searchlight luminosity. Like *radium,* it keeps burning brightly without consuming itself." And I would add, it will not only remain active and *brilliant to the end* but it will, I believe, shed more and more light on the etiology of cancer with every fresh addition *made to the science of* embryology and to our tumours.

ANTITUBERCULOUS SERUM AND "VACCINE."[1]

By Dr. ALEXANDER MARMOREK.

As soon as tuberculin began to be practically known by its effects a question forcibly presented itself—namely, What is the rôle played by this toxic substance as regards the essence of the disease? Is it the real toxin, is it the poison particular to each microbe the action of which is the exclusive, or at least the principal, cause of the pathological lesions? In searching for an answer to these problems we were, above all things, struck by the singular inequalities which a similar dose of tuberculin produced when injected into different subjects—to wit, those who were healthy, those who were affected with tuberculosis in a moderate degree, and those who were practically being poisoned by the bacillus of Koch. In a case of tuberculosis of a mean intensity the explanation commonly given suffices eventually—that is to say, the animal becomes increasingly sensitive to the action of a toxin which it has been itself for some time previous producing in the lesions in its own body. But all the same this explanation leaves untouched the reason for the lighting up of the bacillary foci, which symptom constitutes the local reaction. But, further, it is almost impossible to apply this explanation to cases in which the typical symptoms are very feeble or even absent, as, for instance, after an injection of tuberculin in a cow which is simply stuffed with tubercles. In place of the reaction which the above-mentioned explanation would lead us to expect we see marked insensibility. We therefore have a right to ask why this sensibility (*sensibilisation*) disappears just at the moment when it should be most accentuated. The obscurity of the problem increases when we consider the very marked disproportion which exists between the violence of the reaction and the small dose of tuberculin on the one hand, and on the other hand the very slight degree of lesion existing in individuals so little affected by their chronic intoxication that they can hardly be considered to be ill. It is difficult to suppose that these few bacilli, finding themselves in a focus where the fires of infection are slumbering and almost imperceptible, can be sufficient to transform the indifference of a healthy organism to tuberculin into an almost excessive sensibility. But it is still less easy to understand how an organism which is thoroughly tuberculous, with its innumerable bacilli, all in full working order and of great activity, does not respond with greater energy to the stimulus of tuberculin than is seen, for instance, in the case of a bovine animal that has passed through all the stages of the formation and evolution of its infective centres, one in which everything testifies to a chronic intoxication and which is not sensible (*sensibilisé*) to the action of tuberculin. And yet, according to the above-mentioned theory, a poison should in such an animal have been in process of formation for a long time and the animal should therefore be markedly sensible to the injection.

Contradictions such as these forced us to conclude that the explanation given above must be erroneous or defective. There remained only to find a new explanation which should be more in accordance with observed facts and which would lead us to a new method of research. To attain this end let us consider the situation of the bacillus of Koch in its usual habitat. Surrounded by leucocytes or in the giant cells it apparently secretes so little toxin that the addition of an infinitesimal number of microbes brings about an appreciable change in the affected organism. All of a sudden we stimulate the bacilli by a minimal dose of injected tuberculin which disseminates itself through all the foci of infection. The tuberculous organism, which it is asserted is sensible to the effects of tuberculin, allows many hours to pass before exhibiting any new symptom. It is only after the lapse of a fairly long period of time that the foci of infection inflame and that the whole body resents the effects of the poisoning. Moreover, a tuberculous man after a time ceases to give the typical reaction and if the injections of tuberculin be continued the sensibility diminishes instead of increasing, as it should do were the above-mentioned theory correct. We refuse in face of such contradictions to admit that tuberculin can be the direct cause of the reaction brought about by its injection, that it is a substance identical with that which the bacilli principally form in the sick organism, or that in consequence it is the final chemical reason for the wasting and for the destructive march of the bacilli. But all these difficulties disappear if we replace the current theory by an hypothesis—viz., tuberculin would seem to be in truth a preparatory substance, a reagent which acting on the bacilli stimulates them and induces them to secrete in great abundance a toxin altogether different.

Let us now consider the facts in the light of this hypothesis. Reaction does not commence until a sufficient quantity of time has elapsed to allow a sufficient quantity of toxin to accumulate in a focus of infection. We are present (*assistons*), in fact, at the hatching of the local reaction. When at the end of some hours the toxin secreted by the bacilli begins to be reabsorbed into the circulation the intoxicated organism responds by exhibiting fever. We can formulate our idea as follows. The "tuberculin reaction" is due to the formation of a toxin which the bacillus secretes by reason of, and subsequently to, its stimulation by the tuberculin. It is easy to understand that by this specific effect of the tuberculin on the bacillus (it may almost be compared to a key opening its lock) the most deeply seated collections of tuberculous matter are transformed into a regular furnace for the production of toxin which can be made known by investigation. We can equally understand how it is that every little tubercle containing a few scattered bacillary units will react promptly to a dose of tuberculin which represents a thousandth part of the quantity which is without effect in a healthy individual or even less. We can also understand the almost mathematical accuracy of the axiom "tuberculin reaction means tuberculous focus" Moreover, all the other phenomena which the old theory left uncertain or doubtful to our understanding become perfectly clear.

This explanation of the part played by tuberculin is particularly useful when we consider the two extreme cases of perfectly healthy individuals and of individuals who are highly tuberculous. In the first case, the tolerance exhibited even to a very large dose of tuberculin is due to the absence of the bacilli which are the sole producers of the true toxin so that the presence of bacilli is indispensable to intoxication and from their absence arises the impossibility of the tuberculin being able to produce an effect. In the second case, take, for instance, a cow which is very deeply affected with tuberculosis. The whole sum of the toxins newly produced by the injection of Koch's reagent is quite a negligible quantity compared with the amount of the real toxin which has already accumulated in the many foci of infection and throughout the entire economy of the animal. The bacilli are already at work with extreme activity (do not let us forget that we are speaking of the case of tuberculosis which is very advanced) and are already practically soaked in the toxin. We may well ask ourselves if tuberculin is sometimes able to stimulate the work of the bacilli and to augment it, but in any case the increase of toxin, if indeed there is an increase produced by the tuberculin, is infinitesimal compared with that which has already been secreted owing to the natural evolution of the disease and it is by no means sufficient to cause a new intoxication which will betray itself by reaction. The result, therefore, is identical with the case of a healthy person. In neither case is there any reaction, but the reasons are diametrically opposed to one another.

Other facts which have been ascertained in the study of tuberculin reaction fall in well with our hypothetical explanation. For example, it is quite easy to understand that substances having a similar composition to tuberculin will equally stimulate the bacillus to its secretion. We know well the feeble reactions produced by an injection of extract of lymphatic glands and, on the other hand, it is easy to understand that an organism invaded by the bacillus of lepra, which is so similar to the bacillus of Koch, will give the reaction after injection of tuberculin and, finally, the treatment with tuberculin which was given to the world by the illustrious Koch finds its explanation so far as regards both the undoubted cures produced, and also the checks and the dangers of this method, in the true rôle of tuberculin—viz., the successive production of the true toxin which is poured *out from the bacillary foci into the general circulation.* By tacking carefully between the shoals of this general poisoning and the maintenance of the necessary intervals of time for the formation of an antitoxin which is destined to counterbalance the *intoxication we may sometimes* be able to modify favourably the morbid process, but we can easily see how risky and how prone to dangers is such a proceeding.

---

[1] A paper read before the Paris Academy of Medicine on Nov. 17th, 1903.

Serums have been prepared by the aid of tuberculin and are still being so prepared. As, however, these *serums* attack a substance which only plays a fortuitous rôle, if not, indeed, one which has absolutely no effect in the pathology of tuberculosis, we must not be surprised if these serums, which are wrongly called antituberculous although they are simply antituberculinous, should have no influence upon either the lesions or the progress of the disease.

If our hypothesis is correct—and everything which has been previously said supports the idea that it is so—the principal part in tuberculosis belongs to the hypothetical toxin. Experiment, therefore, should furnish a positive proof both of its existence and of its action. It appeared to us that if the bacillus hitherto has not produced this toxin outside the organism when grown in vitro, it was because it was not grown under conditions which faithfully reproduced those which exist in its habitual environment in the body. We therefore arranged some experiments to reproduce these conditions as far as possible and we proceeded as follows.

In a small communication which I read before the [illegible] Medicine held at Paris in 1900, I [illegible] different phases of the life-history [illegible] bacillus. The young microbes which we designated under the name of "*primitifs*" having different colour reactions should also exhibit different biological *qualities. We then, however, lifted only a corner* of the veil which hid the matter. There appeared to us every indication to employ these young microbes, which are covered with a very delicate shell of a waxy or fatty substance, in the delicate work of producing a toxin, and another reason was that in liquid medium they produce only a very small quantity of tuberculin and that very slowly, for the presence of tuberculin could not be otherwise than disturbing in the research for another toxic matter. We soon saw that these *primitifs*, which within ten or 12 days almost completely covered the surface of the liquid medium in which they were sown, secrete no toxin in their ordinary culture mediums. It remained, therefore, to reproduce more natural conditions. As the bacilli undoubtedly form the substance for which we were searching in the organism—that is to say, within the interior of the leucocytes or after having come out from them—the idea struck us to put them in contact with freshly extracted white blood corpuscles. The experiments made in this direction were long and laborious but with no appreciable result. Convinced, *however, of the accuracy of our hypothesis we were slowly brought to find a proof of it by another* road. We thought, can it be possible that within the bacillary foci the leucocytes do their work not so much by being biological entities as by some substance which is derived from them? We therefore replaced the leucocytes in our experiments by a leucocytic serum obtained in the following manner. We injected into calves, whose receptivity of tuberculosis is well known, the leucocytes of a guinea-pig which is also an animal extremely sensitive to the action of the bacillus of Koch. To obtain these leucocytes was a very simple proceeding. From 10 to 15 cubic centimetres of peptonised bouillon were injected into the peritoneal cavity of a guinea-pig and 48 hours afterwards this was washed out with 20 cubic centimetres of normal salt solution (*eau physiologique*) which came out with a milky appearance, being full of leucocytes. This was injected as soon as possible into a calf. At least 30 injections have to be made, each containing the *leucocytes de* [illegible] *to bring* about the production o[illegible]ucotoxic properties. The primiti[illegible] medium with great difficulty, but [illegible] a process of patient selection and [illegible] quantity of glycerinated bouillon. The great object is to avoid for as long a time as possible the loss of the primitive character of the bacilli, for our observations have taught us that the secretion of tuberculin marches step by step with this transformation of the primitive bacillus which can be recognised by a change in the aspect of the waxy and transparent enveloping membrane, which becomes warty and opaque, and also by the appearance of a specific odour.

The filtrate made from cultures of bacilli grown in this leucotoxic serum medium does not contain tuberculin for a long time, but another toxic substance is discoverable in it. Contrary to what is found in the case of tuberculin, tuberculous animals were no more sensitive to this substance than were healthy ones. When this feebly toxic substance was injected into horses it produced general œdematous patches which in some cases were of considerable size. To increase *the toxic power of this* substance we tried all the culture mediums known and we have also experimented with some new substances, always mixing them with the serum, but without getting any result to satisfy us. One important point, however, was decided. The bacillus *can* be rendered more toxigenous and a more *active producer of true* toxin. Our task was therefore to keep the bacillus in its primitive stage as long as possible in order to permit it to secrete abundantly.

In the course of our researches one fact attracted our attention more and more strongly—viz., a certain degree of immunity which the liver possesses with regard to the invasion of the bacillus. We constantly observed that the animals in the laboratory which were attacked by general tuberculosis showed extreme slowness as regards the infection of the liver, and that very often the liver remained perfectly free from tubercles although all the other organs were stuffed with them. To explain this condition of resistance the anatomical conditions are certainly insufficient and we must, therefore, seek for causes of some chemical nature which are capable of arresting for a certain time the development of the bacillus. If then, we argued, we could force the bacilli to live and to grow in a culture medium containing liver substances it might be possible to obtain a strain of bacilli particularly fit to fight against these hinder*ing (empêchantes) substances. The struggle for life which* would be forced upon the bacillus would augment all its vital qualities and by so much the more would its toxigenous power be increased.

As might have been expected difficulties were at first experienced in accustoming the bacillus to an environment apparently unfavourable to its successful culture. But once we had succeeded we found that the bacillus grew more quickly and with greater freedom than in the control cultures and it remained "primitive" for a longer period. It also became markedly more virulent and when injected into animals rapidly brought about a generalised tuberculosis. Moreover, after passing the bacillus a certain number of times through this new culture medium we were struck by the absence of tuberculin, but we recognised the presence of another toxic substance *wanting the characters of the* Koch reagent. It would almost seem that these two substances *exclude each other from* the *same medium* and that the bacilli are incapable of producing one of them simultaneously with the other. It is possible that in this fact lies the *explanation* of the feeble and tardy appearance of tuberculin in those infected with bacilli (*bacillaires*). The toxin which is formed in the liver bouillon passes easily through a filter. *If a fairly* large dose, say from 12 to 14 cubic centimetres, be given it kills small animals, but this effect is not constant.

Each of the two new culture media which we have described favours the formation of toxin in small quantities. By mixing the leucotoxic serum with the glycerinated liver bouillon a great improvement is obtained. The toxin forms *more quickly and is much more virulent.* The smallest fatal dose for a guinea-pig weighing from 300 to 400 grammes was five cubic centimetres of the filtrate, but in general we prepare a toxin which will kill a rabbit or guinea-pig *of* mean size in eight days' time by a dose of from eight to ten cubic centimetres injected subcutaneously. Tuberculous animals injected with the same dose do not die so quickly and have a more defined power of resistance. This degree of toxic power does not resemble that of other known toxins. We do not disguise that the strength of ours is far from being satisfactory and all our efforts are towards bringing to perfection its preparation which we do not consider yet as definitely settled.

Two experimental courses are now open to us whereby we can prove that this substance is in truth the toxin so long sought. The first is that of immunising animals by means of this toxin against an ulterior bacillary infection. We have done this. From 25 to 30 cubic centimetres of actual toxin are required, given in several injections of from four to five cubic centimetres at proper intervals, to render guinea-pigs resistant to the subcutaneous injection of from one to two drops of a feebly opalescent emulsion of bacilli. This result is the most exact confirmation of the identity of our toxin with that which the bacillus secretes in a tubercle. But there is yet the other course which supplements this proceeding. By immunising animals with filtered cultures we obtain an antitoxic serum. We have experimented with horses in this direction. They reacted very strongly to the increasing injections of toxin. Large swellings were formed; the temperature mounted to 40° C. and more; the animals were very highly tested and the absorption of the swelling was slow. It is not easy to obtain tolerance of the toxin in horses. Every new injection is followed by the same symptoms though manifested with declining virulence and we must therefore allow at least seven or eight months for the preparation of an efficacious serum. It is with the serum of an immunised horse that we have attempted by neutralising the effects of the tuberculous toxin to treat at first with a view to prophylaxis laboratory animals, guinea-pigs, and rabbits. Such a serum prepared without any injection of bacillary bodies, but only by means of injections of the filtrate of the culture, is a new proof of the existence of the action of the tuberculous toxin.

Before giving the result of our experiments with this serum upon the laboratory animals and upon the tuberculous human subject we will return to the consideration of the bacillus rendered assimilable after having been subjected to the influence of leucotoxic serum. Hitherto we have not been able to inject an animal with the bacillus of Koch without causing an abscess. Even when exposed to high temperatures or destroyed by powerful antiseptics the bacilli were never digested by the leucocytes, although these would absorb (*englobent*) them at once. The result is quite different when bacilli are used which have been a long time in contact with the leucotoxic serum. The following is the process. The bacilli are submerged for from ten to 15 days in the leucotoxic serum, which is then replaced with normal salt solution (*eau physiologique*) and brought to a temperature of 100° C. The bacilli thus prepared were transferred to leucocytic serum first, some days later being placed in antituberculous serum. It is then seen that these bacilli injected in weak doses into animals disappear quickly without leaving any trace. Rarely a little infiltration remains but in no case does the inoculation cause any general infection.

As soon as we were able to prove the digestion of the tubercle bacilli the idea came into our minds that the bacillus truly assimilated would be able perhaps to confer a certain immunity on an animal. It is quite possible, in fact, that the absence of a stage of resistance in men or animals proceeds from the absence of digestion of the bacilli. Finally, when we were able to see guinea-pigs and rabbits tolerate without the formation of abscesses repeated injections of strong doses of bacilli thus prepared we inoculated them with living bacilli; and we have been able to prove that even some particularly dangerous inoculations, as, for example, abdominal injections in the guinea-pig and intravenous injections in the rabbit, had no effect, while grave lesions took place in the control animals. The
"vaccine" requires from forced seven days to that the
xplanation given above must be erroneous or defective.
'here remained only to find a new explanation which should
e more in accordance with observed facts and which would
ead us to a new method of research. To attain this end let
s consider the situation of the *bacillus of Koch* in its usual
abitat. Surrounded by leucocytes or in the giant cells it
pparently secretes so little toxin that the addition of an in-
nitesimal number of microbes brings about an appreciable
hange in the affected organism. All of a sudden we
timulate the bacilli by a minimal dose of injected tuber-
ulin which disseminates itself through all the foci of infec-
on. The tuberculous organism, which it is asserted is
ensible to the effects of tuberculin, allows many hours to
ass before exhibiting any new symptom. It is only after
e lapse of a fairly long period of time that the foci of
fection inflame and that the whole body resents the effects
f the poisoning. Moreover, a tuberculous man after a time

03.

later because the immunisation of the horses was not pushed sufficiently far. For these reasons the earlier results are not comparable with those of to-day. The serum, moreover, is capable of improvement and in the future will be made more efficacious.

What can we learn from experiments upon the lower animals? At first we confined our attentions exclusively to guinea-pigs. These animals are extremely sensitive to Koch's bacillus and are difficult to immunise. Strong doses of serum are required to protect them against weak bacillary injections. And how are we to arrive at the measure of efficacity of the serum, allowing that its efficacity is not yet absolute? The test employed in acute diseases—the survival of the animal treated and the death of the control animal—is of no value here. The guinea-pigs display too great differences of individual sensitiveness: the cachexia and the duration of life vary so often in two animals which have been injected under identical conditions. The invariable factor is the regular sequence of anatomical lesions. These were our sole guide in proving the influence, even when slight, of the serum. For these reasons we prefer the rabbit for experiments. Certainly it is less sensitive but effects of injection are more constant. With the rabbit the serum acts in a definite manner upon the artificially produced condition, even at a moment, when its curative influence upon the guinea-pig is only slight. We always produced in the rabbit the severest form of infection by intravenous inoculation. The serum has both a preventive and a curative "action." From 15 to 20 cubic centimetres of serum injected three days before the infection definitely protect the rabbit.

The following oft-repeated experiment is still more interesting. Rabbits of a medium size receive from one to two drops of an emulsion, feebly opalescent, of virulent bacilli in the marginal vein of the ear. Some hours after the infection a group are injected with 20 cubic centimetres of our serum subcutaneously; the next day a second group similarly receive 25 cubic centimetres, and two days afterwards a third group are injected with the same dose. The last groups we inject once again with 20 cubic centimetres. We keep a fourth group for control. 20 days after the infection the control animals exhibit in the lungs countless tubercles as large as a pin's head. At the death of each control animal we kill an animal out of each group They are all found free from tubercle. Those that we do not kill survive in perfect health. For the preventive immunisation of guinea-pigs and rabbits we have proved it very useful to give many small doses, while for treatment we can content ourselves with one large dose. The doses for the two animals are always practically the same, the large size of the rabbit in comparison with the guinea-pig being compensated in the latter by its greater sensitiveness to the bacillus of Koch. A serum not sufficiently active to cure a guinea-pig, although arresting in it the progress of infection, can be efficacious for the rabbit, so it is with the rabbit that the use of the serum should be begun At present we have only the empirical method for testing the serum It is considered sufficiently active if it can prevent the tuberculous process of the lung in a rabbit infected by intravenous injection.

It thus experimentally proved to-day that the serum
it, cts the bacillus of Koch. We admit willingly that
there is an doses have to be used. But we ought not to lose
finitesimal the fact that we have experimented with animals of
secreted owi and excessive sensitiveness and whose natural means
it is by no are certainly insufficient. The rabbit, in com-
which will betra the guinea pig, requires less curative power in

t the whole organism must be under

a powerful toxic influence; among these are included patients having extensive pulmonary lesions (with cavity and persistent fever) and sufferers from meningitis. The second group comprise those affected with severe local tuberculosis which, however, did not seriously interfere with their general health. The order of this grouping corresponds also with the succession in relation to time of the cases treated.

We first treated a comatose child suffering from meningitis and administered small doses (two cubic centimetres) of serum. Even in the cases of meningitis which since that time we have treated with more appropriate doses of serum (40 cubic centimetres per day) the results were equally negative. Sometimes there was hope that the little patient might be saved. Some symptoms, as the increased pulse and respiration, improved distinctly, the paralysis seemed to diminish, the coma disappeared, the meningitis [illegible] this [illegible], was [illegible] veral [illegible] uberculous toxin, in like manner with that of tetanus, for example, is firmly established in the cerebral cells at the time of the manifestation of the definite symptoms, i[illegible] impossible to dislodge the toxin [illegible] act on the meningitis even with a [illegible]e which is now at our disposal. On the other hand, it must not be forgotten that we always appeared on the scene too late, for we were never asked to give injections of serum before the seventh or eighth day, even on the tenth and twelfth day, after the beginning of the illness when all the symptoms of meningitis were fully displayed. There is reason to suppose that treatment commenced much sooner, during the long period of incubation or at the very beginning of the attack, might in some cases have succeeded in averting the fatal result.

We continued our endeavours with very advanced forms of pulmonary tuberculosis presenting large cavities, hectic fever, very extensive infiltration, and histories of many years' duration. In this way proceeding from the most severe cases associated with secondary infections and going on to those which were less advanced, less complicated, and not as yet in the stage of irreparable destruction of tissue, we have passed in review all the forms of tuberculous infection. We soon formed the opinion that the duration of the malady was a feature of the greatest importance. The courtesy of the physicians and surgeons of the Paris hospitals provided us with patients—a favour for which we are deeply indebted to them—and in the course of treating these patients our observations on the influence of the serum led us to the conclusion that the area of the lesion is much less important than its duration. Other things being equal, a lesion which although extensive is recent may be recovered from more quickly and easily than one which is much smaller but of long standing. Almost all the cases of pulmonary tuberculosis which we had to treat were in an advanced stage, with profuse expectoration, with numerous bacilli, very often with feverishness and general ill-health, and sometimes even with cavities.

The forms of tuberculosis which appear to us to be the most appropriate for these trials of a new method of treatment are the forms with which the surgeons have to deal. Being at the outset almost free from troublesome mixed infections the combination of obvious symptoms which they present is such that the results are hardly controvertible. Moreover, these forms are exceptionally favourable for the continuous observation of the effects of the serum treatment, for although we have not had the opportunity of treating many cases in the first stage we consider that as regards the importance of the lesions relatively to the whole organism very advanced cases of surgical tuberculosis correspond fairly well to the initial manifestations of pulmonary and laryngeal tuberculosis. It is for this reason that we attach some value to the results obtained in tuberculosis of the bones, the joints, the glands, and the bladder. With few exceptions all the cases treated by us were of long standing and had for the most part been subjected to a variety of remedial measures. The recovery of such cases after the administration of injections of serum apart from any other form of treatment almost gives to each case the force of a scientific demonstration and an experimentally verified fact.

In several cases of advanced pulmonary tuberculosis which we have had under our care there occurred a manifest and favourable influence not only on the patient's general condition, which improved greatly under the new treatment, but also on the lesions themselves. The amount of the expectoration and the number of the bacilli decreased progressively, the dyspnœa disappeared, and auscultation and percussion revealed a diminution of the areas of infiltration and softening. These cases justified us in predicting that patients in a less advanced stage of pulmonary tuberculosis and treated more perseveringly than the time at our disposal permitted would benefit still more by the serum treatment. Some recoveries which have occurred since that time have proved that this is so. We shall not at present do more than merely mention the important subject of mixed infection in which the streptococcus plays a leading part and in which the prognosis is evidently much less favourable. We are now engaged in endeavouring to elucidate this question.

Pleuritic effusion is a form of bacterial infection which may be considered as intermediate between pulmonary tuberculosis and so-called surgical tuberculosis. This acute disease shows by unmistakable signs the influence of the treatment. In seven cases of this kind (two of which occurred in little children) we found in six cases a rapid diminution of the effused fluid accompanied by very marked diuresis. We think it may be said that in these patients the serum produced a rapid and obvious improvement.

It remains for us to give a concise summary of the permanent recoveries which we have obtained in surgical tuberculosis. We have succeeded in effecting a complete cure of several cases of Pott's disease complicated either with fistula, with abscess, with intestinal perforation, or with palsy of the lower limbs. We have been able to bring about progressive diminution of glandular masses in the neck, the groin, and the true pelvis, as well as to procure the closing of fistulæ which had been open for a long time. In several cases we have observed that the pus at the seat of caseation was re absorbed without any surgical treatment. Multiple granulomata (*gommes*) of the skin, refractory for years to every remedial measure, rapidly dried up and closed. Several times on the obstinate refusal of fistulæ to close we were able to diagnose the presence of a sequestrum as the only cause of the persistence of the suppuration after the cure of the tuberculous process. This diagnosis, based on circumstantial inferences, was always confirmed by the results of operation.

One word on the practical application of the new treatment. It must not be forgotten that this is the first time that a serum has been employed as a remedy for a chronic disease. The serum must be injected in a sufficient quantity divided into several doses. The highest number of injections administered was 52; the lowest was seven in a case of tuberculous glands in the neck and six in a case of sternal fistula. With respect to the occasional inconveniences incidental to serum treatment those due to our serum are the same as, and not more frequent than, those produced by any serum of whatever kind. In about 2000 injections we have only observed a local abscess three times. The serum does not ordinarily give rise to either pyrexia or any disturbance, local or general. On the contrary, the hectic fever, especially that form which is due principally to absorption of tuberculous toxin and in a less degree to mixed infection, declines after several injections of serum. Pyrexia is in no instance a contra-indication for its use. We have even sought out such cases for the purpose of demonstrating on them the antipyrexial action of the serum. As for technical details we propose to give a full account of them on a future occasion.

Such are in brief the results of our work. And here I ask the Academy to allow me to refer to a personal matter. Attached to the Pasteur Institute for many years I find myself in a scientific sense out of harmony with the official heads of the institute in respect of several points in these researches. In order, therefore, to relieve the Pasteur Institute I have felt it to be my duty to resign my position as *chef de laboratoire* so that I may be alone responsible, morally and scientifically, for my work. We are quite aware that for the giving of a definite opinion on the value of our serum experimental evidence on a far larger scale than ours will be required. Investigations in this direction are being carried on in many places, even in foreign countries, under the control of competent clinical observers and some very encouraging results will be published immediately. Taken together with those obtained by us in the laboratory and those observed in many of our patients during more than a year they may justify the presentation of this memoir.

Paris.

injections of from four to five cubic centimetres at proper intervals, *to render guinea-pigs resistant to the subcutaneous injection of from one to two drops of a feebly opalescent emulsion of bacilli.* This result is the most exact confirmation of the identity of our toxin with that which the bacillus secretes in a tubercle. But there is yet the other course which supplements this proceeding. By immunising animals with filtered cultures we obtain an antitoxic serum. We have experimented with horses in this direction. They reacted very strongly to the increasing injections of toxin. Large swellings were formed; the temperature mounted to 40° C. and more; the animals were very highly tested and the absorption of the swelling was slow. It is not easy to obtain tolerance of the toxin in horses. Every new injection is followed by the same symptoms though *manifested with declining virulence and we must therefore* allow at least seven or eight months for the preparation of an efficacious serum. It is with the serum of an immunised horse that we have attempted by neutralising the effects of the tuberculous toxin to treat at first with a view to prophylaxis laboratory animals, guinea-pigs, and rabbits. Such a serum prepared without any injection of bacillary bodies, but only by means of injections of the filtrate of the culture, is a new proof of the existence of the action of the tuberculous toxin.

Before giving the result of our experiments with this serum upon the laboratory animals and upon the tuberculous human subject we will return to the consideration of the bacillus rendered assimilable after having been subjected to the influence of leucotoxic serum. Hitherto we have not been able to inject an animal with the bacillus of Koch without causing an abscess. Even when exposed to high temperatures or destroyed by powerful antiseptics the bacilli were never digested by the leucocytes, although these would absorb (*englobent*) them at once. The result is quite different when bacilli are used which have been a lo
time in contact with the le oxic serum.

later because the immunisation of the horses was not pushed *sufficiently far. For these reasons the earlier* results are no comparable with those of to-day. The serum, moreover, i capable of improvement and in the future will be made more efficacious.

What can we learn from experiments upon the lower animals? At first we confined our attentions exclusively to guinea-pigs. These animals are extremely sensitive to Koch's bacillus and are difficult to immunise. Strong doses of serum are required to protect them against weak bacillary injections. And how are we to arrive at the measure of efficacity of the serum, allowing that its efficacity is not yet absolute? The test employed in acute diseases—the survival of the animal treated and the death of the control animal—is of no value here. *The guinea-pigs display too great differences of individual* sensitiveness: the cachexia and the duration of life vary so often in two animals which have been injected under identical conditions. The invariable factor is the regular sequence of anatomical lesions. These were our sole guide in proving the influence, even when slight, of the serum. For these reasons we prefer the rabbit for experiments. Certainly it is less sensitive but effects of injection are more constant. With the rabbit the serum acts in a definite manner upon the artificially produced condition, even at a moment, when its curative influence upon the guinea-pig is only slight. We always produced in the rabbit the severest form of infection by intravenous inoculation. The serum has both a preventive and a curative "action." From 15 to 20 cubic centimetres of serum injected three days *before the infection* definitely protect the rabbit.

The following oft-repeated experiment is still more interesting. Rabbits of a medium size receive from one to two drops of an emulsion, feebly opalescent, of virulent bacilli in the marginal vein of the ear. Some hours after the infection a group are injected with 20 cubic centimetres of our serum subcutaneously; the next day a second group

ducing im-
munity. Its effect is distinctly lasting. We have been able
to prove already that in the rabbit the resistant state pro-
duced by the injection of six to eight cubic centimetres of
"vaccine" lasts two months.
We do not yet know if the immunity thus acquired can be
prolonged beyond the period experimentally determined.
If it were possible to extend the period of immunity to a
year it would be very interesting to apply the "vaccine"
to cattle, which we propose to do. One point only is to be
remembered. As the identity of bovine and human tuber-
culosis no longer is in doubt it probably will be sufficient to
use for experiments the same "vaccine" that we have
employed for smaller animals and which was derived from
human bacilli. But nothing would be easier if it became
necessary than to prepare according to the same method a
"vaccine" derived from the bacilli of bovine tuberculosis.
We wish now to give an account of the effect of anti-
tuberculous serum upon animals and of the trials made with
it upon human subjects during more than a year. The first
samples of serum at our disposal were much less efficacious
than those which we employed during the last month. This

ov. 17th,

the worst state of the epidemic. These points are shown in Table V.:—

TABLE V.—*Showing in the 50 Villages the Period of the Epidemic when Inoculations were Performed.*

Months.	Number of villages declared infected.	Number of villages inoculated for the first time.	Number of inoculations performed.
October	5	0	0
November... ...	6	2	2386
December... ...	6	2	166
January	4	19	5363
February	17	22	3630
March	13	5	1341
Totals... ...	50	50	12,886

None of these villages had been declared to be free from *infection at the end of March, 1903. They have a total* [illegible] latest census returns of 44,760 [illegible] 1902, to March, 1903, inclusive [illegible] rformed, distributed as to time as shown in Table V.

Thus the total population may be divided into the two classes of uninoculated, numbering 31,874, and inoculated numbering 12,886, both classes living approximately under the same conditions as regards surroundings and risk of infection.

In Table VI. the relative behaviour of these two classes towards plague is set down.

TABLE VI.—*Showing the Relative Behaviour of Uninoculated and Inoculated Persons towards Plague.*

Classes	Number in each.	Cases of plague.	Attack-rate per cent.	Deaths.	Death-rate per cent.	Case mortality per cent.
A. Uninoculated	31,674	1457	4·5	659	2·06	45·2
B. Inoculated ..	12,886	171	1·3	29	0·22	16·9

The percentage of the inoculated to the total population was 28·7. *A slight error lies in the fact that some few persons* were inoculated twice; these were certainly under 1 per cent. of the whole. From this it is evident that Class B (the inoculated) have a decided advantage over Class A (the uninoculated. In Class B the attack-rate of plague is over one-third—nearly one-fourth—of the attack-rate in Class A, the death-rate is one-tenth, and the case mortality is reduced by nearly 30 per cent. In this series of cases the usefulness of the measure would appear to be established and as to its freedom from ill-effects it may be stated that in the whole number of 30,609 inoculations no serious consequences came to light. To speak more exactly abscesses developed in 16 cases at the site of inoculation. 15 of these were traced to one particular bottle of the prophylactic which had become contaminated in some unknown way. The remaining abscess was the only accidental one reported. It may be said with some safety that there were no others, as the people are not at all backward in reporting anything of the kind, and beyond these few septic complications, none of which were ever serious, there were no ill-effects known. The technique recommended by M. Haffkine was adopted throughout, with some little variations suggested by local circumstances, and the almost complete absence of communicated sepsis is, indeed, surprising as well as satisfactory when one considers the very unclean habits of the majority of the people dealt with. In estimating the amount of good done by the prophylactic it must always be assumed that a dose had been given sufficient to insure a good reaction. The utmost importance of this is a matter of firm belief with the writer. The mere inoculation of a number of people exposed to plague with an uncertain small dose of prophylactic gives no criterion of its usefulness. It must be given in a dose that may be reasonably expected to protect against possible infection. The only test of this is the production of a distinct reaction with a temperature of probably at least 102° F. in each individual inoculated. Stress is laid upon this owing to the small attention actually paid to it in the carrying out of the Punjab scheme. [illegible] recommen [illegible] personally [illegible] percentage of cases as possible—10, 20, and 30 hours after inoculation—with a preference to the ten-hour record and the future dose modified accordingly. This is undoubtedly the right course and all the more important in that the prophylactic itself can be only imperfectly standardised, but in my experience at least it was found impossible to carry it out except in a very limited way. This was always a matter of regret, but it was not possible to do more than was done with the allotted staff owing in large part to the number of inoculations performed and to the distance that had to be covered daily.

The plan followed by me to obtain approximate results for future guidance was to get personal reports from each village as to the general state of the people after inoculation. This method, though scientifically useless, was practically of great value in aiding the determination of a dose satisfactory in its reaction but still not powerful enough to make the people afraid of coming forward. It should be recognised how very important it is to educate the people not only to accept inoculation, but also to be dissatisfied with it unless it produces a pronounced reaction. Though the first point is being surely gained—true, in the writer's experience at least—the second is scarcely understood at all. The people come for inoculation, but naturally, in their ignorance, are glad to escape with the minimum of discomfort. This being so, and so long as the individual dose remains uncertain, just so long will Haffkine's prophylactic fail to give the very great protection against plague which it undoubtedly does give under proper circumstances. With perseverance in inoculation and common-sense methods of disinfection and segregation properly and correctly carried out the disease in India would be stayed. The curiously spasmodic and half-hearted measures unfortunately so common [illegible] ean failure. Acknow- [illegible] M.S., for access to his [illegible] to obtain the plague figures in Table VI.

Albion-road, N.

SOME OBSERVATIONS ON OVER 6000 INOCULATIONS AGAINST PLAGUE.

BY J. W. MILLER, M.D. VICT., D.P.H. CANTAB.,
LATE PLAGUE MEDICAL OFFICER, PUNJAB, INDIA.

THE above inoculations were done in the Punjab during 1902 and 1903. Haffkine's prophylactic was used throughout and was supplied in bottles containing 30 cubic centimetres, the maximum dose being from 5 to 7·5 cubic centimetres. A 20 cubic centimetre syringe was used and this as well as the needles used were first sterilised by drawing up oil heated to a temperature of 160° F. into the syringe and leaving the heated oil in contact for a few minutes; the oil was heated by a spirit lamp and this method of sterilisation was found to be very useful as it was rapid and did not take as long as disinfection by boiling. The needles were left in a vessel containing the heated oil for a few minutes; a little of the prophylactic was drawn up into the syringe to wash the oil away before filling it.

The left arm was chosen for inoculation for the sake of convenience and as causing less pain and inconvenience afterwards to the person inoculated. The arm could easily be kept at rest and did not necessitate the patient being kept in the recumbent position, which would have been the case had inoculation been performed in the abdomen or the groin. In some cases inoculation was performed in other situations at the request of the person to be inoculated, a common site being in the situation of the knee, the hip-joint, and shoulder-joint, the idea being that rheumatism and other pains would be cured, and there is no doubt that the counter-irritation produced by the inoculation does in many cases relieve pain. Before inoculation the upper and outer parts of the arm were washed with soap-and-water. This was especially necessary, as a large number of individuals came straight from their work in the fields to be the West Indies. Not only in children but even in adults toxæmic symptoms are not infrequently produced by the presence of these worms which, presumably from the large quantity present, sometimes die and putrefy in the bowels, giving rise to a condition of blood poisoning closely resembling the typhoid state. This condition of ascarides is extremely common in these parts in children varying between the ages of two and ten years. So, therefore, it is always wise in treating children to start by administering a worm powder even if the disease is recognised to be some other, for the presence of worms in the intestines contributes in no small degree to the great irritability to which patients of tender age are prone in all diseases. Round worms are not always easy to expel, for often the large number present are knotted together and not infrequently give rise to symptoms of slight obstruction; at other times they are deeply embedded in mucus and no amount of santonin can get at them, so that the bowels are required to be freely active before the worms can be exposed and acted on by the vermifuge. In reading the letters published in THE LANCET[1] concerning this matter I recalled to mind a case of ascarides once under my care, the notes of which I have by me.

The patient was a fairly well-nourished boy, aged eight years, who was admitted to a hospital on July 27th, 1897, for fever and "bad bowels." He was unconscious; his pupils were widely dilated and the conjunctival reflex was present. The eyes were protruded and deviated upwards and to the right; his teeth were clenched. His bowels were loose and the motions were extremely offensive. The surface of the body was cold. The breathing was free; no abnormal sounds could be detected in the lungs. The heart beats were rapid but otherwise normal. He had several fits and on admission there were noticed twitchings of the right side of the face, the right arm and leg, and the left side of the mouth. The abdomen was much swollen and tympanitic. The pulse was quick and regular. His temperature on admission was 102·6° F. A rectal tube was passed but no flatus came away; a calomel and santonin powder was given and turpentine stupes were applied to the abdomen. Later in the day he was given three grains of acetanilid. At 5 45 P.M. his temperature registered 100·6° and he rallied somewhat, the teeth being less clenched, while the abdominal walls seemed to have become softer, but he was still in a stuporous condition. At 8 P.M. he passed a foul motion and was perspiring freely. The bowels were then washed with weak Condy's fluid—half an ounce in a quart of water. Ice was applied to the head. On the 28th there was some improvement since the previous day. The stupes were discontinued. The pulse and respirations were respectively 160 and 60 per minute, the skin was moist, and the temperature was 100·4°. At 6 P.M. the temperature registered 101·4°. The boy was still unconscious. There were constant movements of the head from left to right. The abdomen was less distended. One-eighth of a grain of calomel with sugar of milk was given every quarter of an hour for eight doses. On the 29th the patient was conscious in the morning and his temperature was normal but he was still very weak. The pulse was 140 per minute and regular. He passed a large and very offensive motion. Another large motion, black in colour, was passed about 11 P.M. The abdomen was flat and no tympanites was present. His aspect was dazed, the lips were dry, and there were sordes on the tongue and the teeth; the left thigh was flexed on the abdomen. He vomited and showed some restlessness. On the 30th he had two dark loose motions and was very restless. On the 31st he was rather poorly in the morning; there were sordes on his lips and teeth and his temperature was 103·8°. He had occasional twitchings of the right half of the body at intervals of four or five minutes; there was spasm of the right arm, the right hand being brought constantly towards the right iliac fossa and vigorous scratching movements were made as if to remove some great irritation. He was given a mixture containing four grains of hydrochlorate of quinine, four grains of bromide of potassium, five minims of infusion of digitalis, and five minims of dilute phosphoric acid to one ounce of water every three hours. Stimulants were prohibited at this juncture. He never rallied but died at 1 A.M. on August 1st.

At the necropsy the body was found to be emaciated and there was peeling of the epidermis over the abdomen. The lungs were normal, as were all the abdominal organs. Round worms were found in the intestines two—were in the ileum, one was occupying the vermiform appendix like a gloved finger with the hind end projecting into the cæcum, and six dead ones were in the large bowel. The mucous membrane of the bowels was in no wise diseased. On examining the brain the meninges were found to be normal, there was the usual quantity of cerebro-spinal fluid, and no gross pathological lesion could be discovered anywhere in the brain substance. The case was at first taken to be one of acute meningitis and it is interesting inasmuch as no explanation could be found to account for the symptoms with the exception of worms found in the bowels. The twitchings of the right arm and the scratching movements which were so marked were suggestive of great discomfort in the region of the iliac fossa, a symptom which, I think, is fully explained by the round worm found occupying the vermiform appendix where the irritation must have been very considerable.

DEFORMITY OF THE HEART IN THE MONGOLIAN IMBECILE.

By CHARLES H. FENNELL, M.A., M.D. OXON., M.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER, DARENTH ASYLUM.

IN a paper read before the Clinical Society of London in 1898 and published in vol. xxxii. of the Transactions Dr. Archibald Garrod described five cases of Mongolian imbecility in which evidence of congenital malformation of the heart was present. All the patients were under three years old and Dr. John Thomson's wide experience was quoted as not including a child of more advanced years showing cardiac deformity. The suggestion was made that Mongolian imbeciles thus affected probably died in very early years. I have therefore thought it of interest to record three cases, varying in age from nine to 27 years, met with in the detailed examination of 23 of these imbeciles at Darenth Asylum.

CASE 1.—Male, aged 27 years, a very definite specimen of the type. He is a low-grade imbecile, in good health, and not at all anæmic. The area of cardiac dulness extends one and a half fingers' breadth to the right of the sternum; on the left side it reaches the nipple line. A to-and-fro murmur is heard in the upper three intercostal spaces on each side of the sternum, but best in the second left space and better along the left sternal border than the right. There is no cyanosis or clubbing and the patient has had no syncopal attacks; his heart works adequately and he is a useful ward helper.

CASE 2.—Female, aged nine years, a low-grade imbecile of well-marked Mongolian type. She is in fair health but subject to catarrh. The area of cardiac dulness extends one and a half fingers' breadth to the right of the sternum; its left limit is half a finger's breadth inside the nipple line. There is a diastolic bruit at the left base, replacing the pulmonary second sound and best heard in the second left intercostal space. No systolic bruit is audible. The child shows no cyanosis or clubbing but the circulation in her extremities is poor. She is rather torpid and inactive and has shown no signs of cardiac failure.

CASE 3.—Male, aged 13 years, whose imbecility is definitely Mongolian in type. He is a medium-grade imbecile in good health. The area of cardiac dulness is not increased towards the right; on the left it extends beyond the nipple line by a finger's breadth. A double murmur is present at the base and is heard better on the left side. There is a loud apical systolic murmur heard also all over the left chest and to a less extent over the right chest also. A systolic thrill is felt at the apex. There is no cyanosis or clubbing and the heart acts well. The boy is a poor walker but is learning to make himself useful.

It is well known that the presence of malformation of the heart is often hard to determine during life. I have twice encountered it in necropsies on infant Mongolian imbeciles when it had not been suspected. Probably, therefore, it exists unrecognised in a larger percentage of adolescent cases than my figures would indicate.

Darenth.

A CASE OF TRAUMATIC ANEURYSM OF THE FEMORAL ARTERY IN HUNTER'S CANAL.

BY JOHN CROPPER, M.D., B.C. CANTAB.

THE following case well illustrates many of the difficulties likely to be met with in a large traumatic aneurysm.

A man, aged 25 years, a peasant, was admitted to the English Hospital of the Church Missionary Society Medical Mission at Nablus, Palestine, on June 22nd, 1903, for traumatic aneurysm of the right femoral artery. It had been caused by a punctured wound inflicted four months before. The patient, who was considerably under five feet in height, was otherwise strong; though unable to do his work he had walked to the hospital from his village (Hawârah), several miles distant. He had a good deal of pain.

On admission the aneurysm was found to occupy the inner aspect of the middle third of the thigh; pulsation was well marked, a loud bruit was present, and thrill was easily felt. There was nothing to show whether the aneurysm arose from the main vessel or from a small branch in close contiguity with it. Chloroform having been administered an incision was made down to the sac through the cicatrix which was over the inner border of the sartorius, the sac was opened and clots of blood were turned out to the amount of about a pint. On exploration with the finger, the tourniquet being relaxed, the mouth of the sac could be felt to communicate directly with the main vessel under the muscle and hæmorrhage was easily controlled by the finger. A second incision was then made to the outer side of the sartorius, where by pushing up the sac from the former incision the femoral artery was with some difficulty made out owing to the matting of the tissues. The artery was of comparatively small size from establishment of the collateral circulation but it had the usual relations; it was tied in two places an inch apart, above and below the mouth of the sac, which latter was excised. On finally relaxing the tourniquet the vein was found to have been wounded and, being difficult to secure, hæmorrhage was controlled by firm packing with iodoform gauze. The sac was drained from below. At no time after the operation was there any coldness of the leg which was well raised during the first four or five hours and, indeed, until the patient complained of a good deal of discomfort. The temperature did not at any time exceed 99° F. On the fourth day, feeling quite well, he got up and walked to the lavatory when no one happened to be looking but in spite of this he made an uninterrupted recovery. The gauze was removed on the sixth day; there was then slight discharge from the sac but at no time was there any fever and he went home on the twenty-ninth day from the operation

Nablus, Palestine.

VENTILATION.—On Tuesday, Dec. 8th, the directors of Spiers and Pond, Limited, invited a numerous company to dinner at the Criterion Restaurant to inspect alterations and redecorations of certain of the rooms of the building, and more es[illegible] test the effect of the ventilation of the "[illegible] took place. The system [illegible] igned by Dr. T. Glover Ly[illegible] ready been fully described and commented on in our columns (see THE LANCET, March 1st, 1902). The result appeared to give general satisfaction, there being plenty of air diffused throughout the room during dinner, and although some 80 persons were present in a room 52 feet in length by 24 feet in width the after-dinner tobacco smoke was certainly very much less noticeable and aggressive than it would have been under ordinary conditions. The occasion was a pleasant one, the conjunction of an excellent dinner, a menu which declared in bold type "No speeches," and a well-ventilated room not being an every-day experience [illegible]

ROYAL FREE HOSPITAL.

A CASE OF PYÆMIA (SEPTICÆMIA) SIMULATING ACUTE RHEUMATISM.

(Under the care of Dr. H. SAINSBURY.)

FOR the notes of the case we are indebted to Mr. John A. West.

A lad, aged 16 years, was admitted into the Royal Free Hospital on Jan. 13th, 1903, complaining of pain in the right knee and in the left side of the chest. He had been an out-patient since the 3rd with pains first in the right and then in the left knee. The pain subsequently disappeared from the left knee to return to the right. Before the 3rd he had been quite well. The pains had not been entirely confined to the joints but had extended somewhat along the limbs. There [illegible] history of chill and none of rheumatic fever. [illegible] 102·6° F.; the right knee [illegible] tenderness extending [illegible] the leg; the tongue was [illegible] urates. Examination of the chest gave no explanation for the pain complained of in the left side of the chest. There was a systolic bruit at the apex of the heart which was conducted into the axilla, but no evidence of dilatation or hypertrophy. There was no urethral discharge. In spite of salicylates (including aspirin) the fever persisted; it was very broken in type, remittent or intermittent, the maxima reaching from 102° to 103°, and on one occasion 104°. There were no rigors and no sweatings. Slowly the fever subsided, the temperature reaching the normal about the 31st. On Feb. 5th a recrudescence of the fever occurred, but at a lower level, except on the 5th when the temperature reached 105°. The left knee now became affected. Again the fever subsided till the 10th, when a fresh recrudescence appeared with a return of pain and swelling in the right knee. 14 days of irregular pyrexia followed, during which the left ankle became painful. From the 28th to March 9th the temperature was nearly normal. It then began to oscillate up to from 100·5° to 101°. Between March 10th and the 13th a swelling gradual[illegible] inner side of the right thigh [illegible] prolonged pyrexia, examinat[illegible] diazo reactions gave negative [illegible] blood gave no cultures. No enlargement of the spleen was detected. Mr. E. W. Roughton diagnosed an abscess under the muscles of the thigh and on opening it was able to trace it to a sequestrum in the lower end of the femur. After the operation the boy slowly recovered.

Remarks by Dr. SAINSBURY.—With so definite a local cause it is of interest to note the multiple and shifting arthritis (both knees and the left ankle), and to note, moreover, that the swelling in the left knee was quite as severe as that in the right. In each knee, indeed, the swelling was on occasion considerable with well-marked fluctuation. The diagnosis of acute rheumatism made on admission was strengthened by the presence of a systolic bruit at the apex, but the resistance to salicylates made one suspect that the case might prove to be septic. In the absence of a urethral discharge or of any obvious site of infection, in the absence also of a blood culture, it was impossible to make a more definite diagnosis. Quinine in full doses made no impression and the only treatment which seemed to influence the joints was blistering. This appeared on more than one occasion to lessen the pain and the swelling. The case resembles closely Dr. Moxon's case of pyæmia simulating acute rheumatism recorded in 1877 and described in Fagge's[1] and in relation to modern views as to the dependence of the rheumatic group on sepsis of one kind or another it is not without interest.

ROYAL ALBERT HOSPITAL, DEVONPORT.

PAROVARIAN CYST WITH TWISTED PEDICLE.

(Under the care of Dr. ALONZO G. RIDER.)

FOR the notes of the case we are indebted to Mr. H. M. Major, assistant house surgeon.

The patient, a multipara, aged 40 years, was admitted into the Royal Albert Hospital, Devonport, on Oct. 29th, 1903, with the following history. About 2 A.M. on this date she was suddenly seized with violent pain in the right iliac region, accompanied by bilious vomiting and faintness. She was sent to the hospital and on admission her temperature was 101° F. The pain was paroxysmal, starting in the right iliac region, spreading over the lower part of the abdomen, and extending into the right groin over the hip and down the outer part of the thigh. Vomiting ceased soon after admission. Examination revealed a globular swelling situated a little to the right of the median line evidently containing fluid and reaching a finger's breadth above the umbilicus (it simulated exactly a distended urinary bladder). Vaginal examination showed that the uterus was drawn up and that the swelling sprang from the neighbourhood of the right tube.

Three years previously the patient had noticed some enlargement of the abdomen on the right side and tenderness over a similar area. About three weeks later, while at her house work, she had a sudden attack of pain in the right side which lasted two or three days. There was no vomiting and the bowels were regular in their action. Since then there had been several similar attacks at various intervals but with increasing severity and frequency. The attacks did not coincide with menstruation. In May, 1902, an attack occurred of much greater severity which lasted seven days. Frequent vomiting occurred during the attack. In the following June she was delivered at term of a child—a breech presentation. She had another severe attack in November, 1902. In April, 1903, she had another child at term, again with a breech presentation.

On opening the abdomen through the right rectus a quantity of blood-stained fluid escaped from the peritoneal cavity. The peritoneum showed signs of old inflammation and was very much thickened. The cyst was emptied of about one and a half pints of bloody fluid. On tracing it down to its pedicle it was found to be twisted twice (the rotation having taken place from left to right). The right tube and ovary were lying on its anterior surface at the lower portion. The tube was filled with recent clot and the fimbriæ were glued to the cyst wall by a large clot. There was a considerable clot of recent blood in the right mesometrium. The cyst was unilocular and its wall, which was over one third of an inch in thickness, was composed of laminated blood clot. Microscopic examination of the wall showed it to be (according to the report of the Clinical Research Association) "chiefly composed of blood clot which is undergoing organisation on one side and has a fibrous capsule on the opposite side. There are no traces of ovarian tissue or of unstriped muscle." Dr. G. F. Blacker, University College Hospital, London, very kindly examined the specimen and reported it as "an interesting case of parovarian cyst with twisted pedicle—a rare thing." The abdominal wound healed by first intention and the patient made an uninterrupted recovery.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The annual meeting of the governors of the Royal Albert Hospital, Devonport, was held on Oct. 30th, under the presidency of Admiral Sir E Seymour. The annual report stated that for the 12 months ended Sept. 30th 659 in-patients had been admitted, an excess of 60 compared with the preceding year. The average daily number of patients was 42·64 There were 85 women treated in the lock ward up to May 1st, on which date the ward was closed, as the Admiralty declined to continue further their contribution to its support 164 patients and nurses had been sent to the Pearn Convalescent Home. The financial statement showed that the total cost of maintenance was £4389 compared with £5240 in the previous year, and the unfavourable balance of £1866 with which the year commenced had been reduced to £537.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Artificial Respiration in the Human Subject.

A MEETING of this society was held on Dec. 8th, Mr. A. WILLETT, the President, being in the chair.

In Professor E. A. SCHÄFER'S absence the secretary read a description of a Simple and Efficient Method of performing Artificial Respiration in the Human Subject, especially in cases of Drowning, to which were appended instructions for the treatment of the apparently drowned. The mechanical methods of performing artificial respiration in the human subject which had been most in use up to the present time were: (1) the Marshall Hall method, which consisted in placing the subject upon his side and rolling the body alternately into the prone and back again into the lateral or latero-supine position; (2) the Silvester method, in which the capacity of the chest was increased by raising the arms above the head and thus dragging upon and elevating the ribs, the chest being emptied by placing the arms against the sides of the chest and exerting lateral pressure on the thorax; the subject was throughout in the supine position; and (3) the Howard method, which consisted in emptying the thorax by forcibly compressing the lower part of the chest with a slight upward push so as to raise the lower ribs; on relaxing the pressure the chest again filled with air. The subject was throughout in the supine position. It had been shown that all these methods were efficacious in effecting a normal amount of air exchange in the healthy living human subject, but each one of them was attended by certain disadvantages which became accentuated when the subject was in an asphyxiated condition and especially when the asphyxia was due to drowning. For in these circumstances all the muscles were in a limp relaxed condition; when the head was thrown back, as when the subject was supine, there was a tendency for the tongue to fall back into, and to block, the pharynx; there might be water in the air passages, and an abundance of mucus was usually secreted, which becoming churned up into a froth with the air and water tended to block the air passages. There was also an enormous congestion and swelling of the liver, combined with, and caused by, great distension of the heart, especially of the right cavities This last-named circumstance—viz., the congestion of the liver—rendered the application of the Howard method extremely dangerous in cases of drowning, since forcible pressure upon the lower chest under these conditions was apt to produce rupture of the liver, an accident which occurred on several occasions in the dogs experimented upon by Dr. Herring and Professor Schäfer in their investigations into this subject for the committee of the Royal Medical and Chirurgical Society. The supine position was strongly contraindicated (1) on account of the tendency which there was in this position for the tongue to fall back, and (2) because this position did not facilitate but rather hindered the escape of the water, mucus, and froth from the air passages, throat, and mouth. The Marshall Hall method had not these disadvantages but it involved a large amount of physical labour, and the rolling of a heavy inert body over upon hard ground or upon the planks of a boat might easily produce bruising and superficial injuries which it should be their endeavour to avoid. The Silvester method, besides the objection that it involved the supine position, an objection which was peculiarly applicable to drowning cases, also demanded a considerable amount of physical exertion, and the dragging upon the humero-thoracic muscles tended to strain and otherwise to injure them. From the physiological point of view there was a fundamental difference between the Silvester method on the one hand and the Howard method on the other, since the Silvester method was active in producing inspiration while expiration was passive, whilst in the Howard and other pressure methods expiration was produced actively and inspiration was passive. Since the former appeared more exactly to imitate the normal conditions of respiration it might at first sight be supposed on that account to be preferable, but there was another element to take into consideration—*viz.*, the part which was played by the nervous centre of respiration. For it had been shown (by Herring and Brener and by Head) that a main factor in exciting inspiration was the emptying and concomitant collapse of the lungs, so that if they were mechanically caused to collapse the inspiratory centre was stimulated through fibres of the vagus nerves distributed to the lungs and when the centre was acting a normal inspiration was the result of such stimulation. On the other hand, mechanical inflation of the lungs had a tendency to inhibit inspiration and to depress the activity of the respiratory centre. During complete asphyxia the activity of that centre was in abeyance, but as the subject began to pass out of the asphyxial condition it tended to resume its functions and it was therefore clearly preferable to employ a method of artificial respiration which would stimulate the centre to activity rather than one which would depress its activity. Hence any pressure method was on physiological grounds to be preferred to a traction method—apart altogether from the greater simplicity of manipulation. Further, for the reasons above given, the prone position was to be preferred to the supine, especially in cases of drowning. The method about to be described presented none of the disadvantages which had been enumerated in considering the older methods. It was safe, efficient, and involved a minimum amount of labour on the part of the operator. It consisted in laying the subject in the prone posture, preferably on the ground, with a thick folded garment underneath the chest and the arms laid forward. The operator put himself in a position athwart the subject, facing his head and kneeling upon one knee with the other knee and hip flexed, and placed his hands on each side over the lower part of the back of the chest. He then slowly threw the weight of his body forward to bear upon his own arms and thus pressed upon the thorax of the subject and forced air out of the lungs. This being effected he gradually relaxed the pressure by bringing his own body up again to a more erect position but without moving the hands; as he did this air was drawn, by the removal of pressure from the chest walls and by their elastic reaction, into the lungs. This process was repeated quite regularly and without manifest intervals between the movements at least once every five seconds—i.e., not less often than 12 times a minute; it might be done somewhat more rapidly, but 15 times a minute would in any case be sufficient. By this means it was easily possible in an average man to effect an exchange of nearly 500 cubic centimetres per respiration—an amount which was more than enough to maintain complete aeration of the blood. The advantages of this method might be thus enumerated: 1. The ease with which the physical operations necessary to carry on artificial respiration might be performed; hardly any muscular exertion was required. 2. The efficiency of the gaseous exchange produced by it between the outside air and the air in the lungs. 3 The extreme simplicity of the procedure; no complex manipulations were required. 4 The impossibility of the air passages being blocked by the falling back of the tongue into the pharynx. 5. In cases of drowning the readiness with which water and mucus were expelled from the air passages through the mouth and nostrils. 6. It involved no risk of injury to the congested liver or to any other organ. The following instructions for the treatment of the apparently drowned were given. Immediately on removal from the water, place the patient face downwards on the ground with a folded coat under the lower part of the chest. Not a moment must be wasted by removing clothing If respiration has ceased artificial respiration is to be commenced at once; every instant of delay is serious To effect artificial respiration put yourself athwart the patient's body in a half-kneeling posture and facing his head. Place your hands flat over the lower part of the back of the chest, one on each side and gradually throw the weight of your body forward on to them so as to produce firm pressure—which must not be violent—upon the patient's chest. By this means the air and water are driven out of the patient's lungs. Immediately thereafter raise your body slowly so as to remove the pressure but leaving your hands in position. Repeat this forward and backward movement (pressure and relaxation of pressure) about every five seconds. In other words, sway your body slowly forwards and backwards upon your arms about 12 times a minute, without any marked pause between the movements. This course must be pursued for at least half an hour, or until the natural respirations are resumed. (If they are resumed and, as sometimes happens, again tend to fail, the process of artificial respiration must be again resorted to as before.) Whilst one person is carrying out artificial respiration in this way others may, if there be opportunity, busy themselves with applying hot flannels to the body and limbs and hot bottles to the feet; but no attempt should be made to remove the wet clothing or to give any restoratives by the mouth until natural breathing has commenced.

Dr. R L. **Bowles** regretted Professor Schäfer's absence. He said that there were but few points in which he did not agree, for the method which Professor Schäfer described was almost exactly that which he (Dr. Bowles) had advocated for the last 45 years and had been described as the Marshall Hall method. He only took exception to the method because it was not sufficient and it was necessary in many cases to supplement it by turning the patient into the position which he had described—viz., on to one side, and it was important that the patient should always be rotated on to the same side. To emphasise the importance of this point he said that in cases of apoplexy he had found that the lung on the side on which the patient was lying might present all the signs of consolidation and that when the patient was turned on to the opposite side an alarming increase of the dyspnœa had resulted, and it was only by turning the patient again on to the same side that a fatal issue was averted. He had noticed the same condition in hæmorrhage from the lungs. After the first and second movements had been repeated in succession for ten minutes it was advisable to pass to the third movement in which each time the patient was rolled from the stomach on to the right side; the uppermost arm was raised above the head in a line with the body. The movement expanded the chest and allowed more air to enter the uppermost lung. He thought that there was considerable danger in treating patients in the supine position Professor Schäfer's method was good but it was not sufficient.

Dr. H R. **Silvester** said that the method advocated and described by the author as 'simple and efficient" had the merit of being extremely ancient, having been practised in principle from time immemorial down to the eighteenth century and might be called the simple compression method. Before the importance of the function of respiration was fully appreciated it was probable that the object sought was the removal of the water from the body of the drowned person which was believed to be the cause of danger, and there was no doubt that water when swallowed could be by this simple means removed from the stomach, although not from the lungs, which seldom or never contained any great amount. Dr. Silvester then quoted the earliest recorded cases in which the rolling method was used. With regard to respiration he said that the directions given by Professor Schafer would generally be admitted to be faulty in principle, for expiration was made to precede inspiration, whereas expiration was second in order and not the primary act. In stillborn infants whose lungs had never been inflated, forced expiration at first was impossible and a similar remark might be applied to the Marshall Hall method. With regard to inspiration, after quoting the instructions given by Professor Schafer, he said that the natural expansion of the chest was dependent on little more than the elasticity of the costal tissues and could only take place feebly and inefficiently unless it received some active mechanical aid, but when the unconscious patient was lying with the weight of a heavy body resting on the most mobile part of the thorax he was under the most serious disadvantage. In order to avoid this the plan of rolling was to be preferred, for by rolling the patient backwards the natural resiliency of the ribs was allowed full play and air was drawn into the lungs. The rolling method was, therefore, in this particular decidedly preferable, but the advantage of the rolling method was unfortunately somewhat neutralised by the danger of fracturing the cervical vertebræ and the fatigue of turning the almost lifeless body alternately on the chest and on the back 15 times in a minute for some hours. The congested condition of the heart and thoracic viscera also rendered the pressure of the prone position quite inadmissible in the treatment of asphyxia. Free elevation of the ribs in the supine position and the consequent tendency to a vacuum was much more calculated to remove the state of congestion. The next point considered was the amount of air respired by this method. It was found that the amount of air inspired was exceedingly small and compared very unfavourably with the amount obtained in the Silvester method. With regard to the amount of pressure likely to be exerted in following out the instructions given by Professor Schäfer when carried out by a seafaring population he said that the pressure on the patient's chest would not be less than from 30 to 40 pounds. He thought that another great objection to this form of treatment was that it could not be carried out in a hot bath. In conclusion, he said that the disadvantages of the suggested treatment were: first, that expiration was made to precede inspiration when the condition of the chest was already in a state of expiration; secondly, that inspiration was opposed by the weight of the patient resting on the front of his chest when every encouragement should be given to the re-establishment of the respiratory functions; thirdly, that pressure on the thorax must be injurious when the heart and thoracic viscera were already in a state of congestion; fourthly, that the prone position was objectionable on account of its limiting the expansion of the chest and also by allowing the contents of the stomach to pass into the wind pipe; fifthly, that the amount of air inspired was much smaller than by other methods; sixthly, that a dangerous pressure might be exerted on the costal parietes; and seventhly, that the employment of the hot bath was impossible.

Mr. J. WARRINGTON HAWARD said that there were certain advantages and certain disadvantages in the various methods which had been advocated, but by a combination of the various methods in the manner suggested by Dr. Bowles he thought that the greatest advantage could be obtained. He thought that the patient in the first instance should be placed in the prone position, for it was of no use to draw air into the lungs until the fluid had been expelled as it formed an obstruction to the entrance of air. The position which was suitable for a person drowned was not suitable for a patient under an anæsthetic. The prone position placed pressure on the thoracic viscera, as Dr. Silvester had pointed out, and this was certainly an objection to the maintenance of the position. He emphasised the importance of keeping one lung clear and stated that no attempt should be made to relieve the congestion of the lower lung by turning the patient on to the opposite side. He considered that the method suggested by Dr. Bowles was to be preferred to any other and was of opinion that the society should now come to some definite conclusions on the subject and should publish the result of those conclusions.

Dr. F. W. HEWITT said that in cases of asphyxia arising from anæsthesia he considered it bad treatment to place the patient into a prone position and he had frequently noticed that faulty positions such as had sometimes to be assumed in operations embarrassed respiration. He referred to the case of a child, aged two years, to whom he had given an anæsthetic and during recovery breathing became difficult. He had compressed the chest and with each compression the inspiration became less and less till at the fifth compression no air entered the chest. It seemed that air was forced out but the mucus acted as a kind of valve and prevented the ingress of air. He thought that inspiration should be at once assisted and not only expiration.

Dr. M. S. PEMBREY said that he did not think that the experiments of Hering and Breuer could be used by Professor Schäfer in support of his view, since in the case of a person drowned the nerve centres were in complete abeyance. Respiration would go on after section of both vagi and the important factors in the mechanism were the deficiency of oxygen and the excess of carbon dioxide. He considered that respiration was of especial importance, as it favoured the circulation of the blood through the lungs and hence the centres in the medulla would be better supplied and the distension of the right side of the heart would be relieved. He considered that the method advocated by Professor Schäfer was absolutely useless in the case of an infant and suggested that the method of blowing air into the chest would be more effective. He then dealt with the difficulty met with in artificial respiration in patients with a rigid thorax. He considered that warmth was of great importance, since cold depressed the activity of the nervous centres.

Dr. NEWTON PITT alluded to the statement made that rupture of the liver might be produced by the use of Howard's method. He thought that it would be of great importance that any such case should be put on record.

The PRESIDENT said that the matter had been most thoroughly investigated by the committee and the society had now reached a stage when it would be possible to formulate rules for the treatment of the apparently drowned.

OBSTETRICAL SOCIETY OF LONDON.

Hydatidiform Mole.—Fate of the Ovum and Graafian Follicle in Premenstrual Ages.—Exhibition of Specimens.

A MEETING of this society was held on Dec. 2nd, Dr. EDWARD MALINS, the President, being in the chair.

Mr. J. D. MALCOLM and Dr. R. HAMILTON BELL contributed a paper on a case of Hydatidiform Mole with Bilateral Cystic Disease of the Ovaries and invasion of the muscular wall of the uterus by chorio-epithelioma, the patient being quite well two years after removal of the parts. The patient came under the care of Dr. Malcolm Mackintosh on April 10th, 1901. She had a rapidly enlarging uterus, from which there were free hæmorrhages on April 9th, 14th, and 19th. The patient asserted that if pregnant she must have conceived on Feb. 17th. Mr. Malcolm saw her in consultation on April 29th and she was admitted to the Samaritan Free Hospital on the 30th. The first diagnosis was that the patient had a soft rapidly growing fibroid tumour. Subsequently it was thought that the condition might be one of ordinary pregnancy. Dr. Bell suggested that there might be a hydatidiform mole. Delivery of the uterine contents being imminent on May 8th Dr. Bell, after a consultation, emptied and curetted the uterus, the fundus of which was above the navel. A large quantity of hydatidiform material was evacuated. The uterus was again curetted on May 12th. On the 29th the conditions were unsatisfactory and the diagnosis was uncertain. Mr. Malcolm opened the abdomen and removed two ovarian tumours, the right one having a twisted pedicle. The condition of the uterus did not seem normal and it also was removed, the cervix being taken with it. The patient recovered and had remained well.—Dr. CUTHBERT H. J. LOCKYER said that the pathological interest of this specimen lay, first, in the discovery of two metastatic deposits of chorio epithelioma in the muscular wall of the uterus three weeks after the removal of a hydatidiform mole; secondly, in the concurrence of bilateral ovarian cysts and malignant vesicular disease of the chorion; and thirdly, in the type of cystic ovarian disease. In regard to the latter point the question whether the cysts arose from corpora lutea had not yet been definitely settled. No lutein cells had been discovered in the walls of the few loculi examined, but it was Dr. Lockyer's intention to extend this investigation to other loculi before excluding the possibility of corpora lutea being the source of origin of the cysts. The literature bearing on the etiology of vesicular mole was referred to, Marchand's view being that cystic ovarian disease might influence the development of the ovum, whilst Veit regarded the endometrium as accountable for ovular degeneration and Findlay disallowed an etiological association between ovarian degeneration and vesicular mole. Other instances where vesicular mole and chorio-epithelioma had been associated with bilateral or single ovarian cysts were mentioned, some of these cases being recorded in full.—Dr. PETER HORROCKS congratulated Mr. Malcolm and all those concerned in the happy issue of the case and laid stress on the great superiority of the finger over the curette in the removal of a hydatid mole.—Dr. HERBERT R. SPENCER agreed with Dr. Horrocks that curetting was a dangerous method of removing a mole and thought from an examination of one of the specimens that the growth had been insulated by the curette. He did not approve of Mr. Malcolm's intention to remove the uterus by the supravaginal amputation. Whatever views might be held as to the relative advantages of amputation and total hysterectomy in the case of fibroids he thought that in suspected malignant disease, and especially in chorion-epithelioma, in which growths were known to occur in the cervix, total hysterectomy should be performed.—Mrs. SCHARLIEB gave a short account of a case of vesicular mole complicated with double multilocular ovarian cysts.—Dr. BELL, in reply, admitted that the use of the curette was not usually advisable in cases of hydatidiform mole and in the only other two cases which had come under his own care he had been able to evacuate the uterus with the ovum forceps and the finger. This case, however, was exceptional. After removing the bulk of the tumour with the ovum forceps he put in a finger to scrape away the rest but it proved very tough. The hæmorrhage was considerable and the condition of the woman, bad before the operation began, was now very serious. It was in these circumstances that it was determined to use the flushing curette which checked the hæmorrhage and was more expeditious. The special circumstances of the case, he thought, had not been made sufficiently plain in the paper and it had appeared as if he advocated the use of the curette in all cases. This was not the case and after the remarks of Dr. Horrocks and Dr. Spencer he would probably hesitate still more in the future than he had done on this occasion.—Mr. MALCOLM supported Dr. Bell's view that in this particular case it was impossible to remove all the hydatidiform material with the finger; indeed, it was thought that at the first operation all the disease was not removed by the [illegible] was not likely that the new [illegible] digital examination because [illegible] eply placed in the uterine muscle. The suggestion that a wound made by the curette might have allowed the disease to gain access to the tissues might be correct but it did not seem necessary to assume the existence of a wound if a new growth were adherent to the interior of the uterus. As regarded the removal of the body of the uterus first and the cervix afterwards it would have been better to remove both at once, but the removal of the body was undertaken rather as a precaution than on account [illegible] and the cervix had always [illegible] spicious parts were observed [illegible] he cervix also, and this was done.

Dr. T. G. STEVENS gave a lantern demonstration on the Fate of the Ovum and Graafian Follicle in Premenstrual Ages.—Dr. T. W. EDEN said, in expressing admiration for Dr. Stevens's work, that the latter could claim the credit of being a pioneer. The most interesting part of the demonstration consisted in the method by which the ovum was disposed of in the contracting follicles. If Dr. Stevens's view were correct, the normal protective and nutritive functions of the cells of the membrana granulosa became suddenly suspended when the follicle had reached a certain stage of development and destructive functions were exercised by the same cells instead. This reversal of the direction of physiological activity was, to say the least, very remarkable and it had no analogue in any other part of the body. He felt bound to say that he was not absolutely convinced that the destructive cells were really cells of the membrana granulosa. He thought it possible, notwithstanding Dr. Stevens's arguments, that they might be leucocytes. The weak point in Dr. Stevens's case consisted in the fact that his material was all post-mortem material. No importance could therefore be rightly attached to the absence of signs of diapedesis; this was a vital [illegible] not be studied in dead tissues. [illegible] that the staining reactions of [illegible] entirely different if they could be obtained in the living state.—Dr. HORROCKS, who congratulated Dr. Stevens on the scientific spirit and admirable manner of his address, asked if the slides as shown on the screen represented not merely different degrees of development of the ovum, but also different ages of the children from whom the ovaries had been taken? Thus, was the most fully developed ovum from the oldest child and the most immature from the youngest? He thought it very strange if Dr. Stevens's observations were correct that the ovaries should develop ova up to a certain degree of maturity and then develop cells to devour them. It would be of great scientific value if Dr. Stevens would continue his researches into the condition of the ova developing in ovaries of girls right up to the establishment of puberty.—Dr. C. HUBERT ROBERTS having added his testimony to the excellence of the paper, asked for further information with regard to the origin of the liquor folliculi. He did not think Dr. Stevens had made it at all clear what was the exact [illegible] membrana granulosa and that the [illegible] phagocytosis to a considerable degree.—Dr. G. F. BLACKER thought that there were several difficulties in the way of accepting Dr. Stevens's views as to the part played by the cells of the membrana granulosa in the destruction of the ovum, and the phagocytic action which he wished to assign to them. Nagel in his work on the ovum had held that the zona radiata was really a part of the innermost layer of the cells of the membrana granulosa. If this was so then the theory that the cells of the membrana granulosa burst through the zona radiata and then invaded the ovum could hardly be correct. Further than this these cells were degenerating and such cells did not as a rule take on such important functions as phagocytosis. He thought that the cells found lying within the ovum were probably more of the nature of cell inclusions.—Dr. W. F. V. BONNEY thought that Dr. Stevens's specimens showed very clearly that in premenstrual life the cells of the tunica granulosa retrograded *pari passu* with the ovum, whilst in adult sexual life they continued to grow after dehiscence of the follicle and formed the lutein layer of the corpus luteum. He had examined Dr. Stevens's specimens attentively and could find in them nothing at all resembling a lutein layer. Seeing that much recent work by various observers tended towards a conception which allotted to the luteum layer the function of producing the internal secretion of the ovary, and seeing further that the most striking point of difference between the generative organs of the child and adult respectively lay in the fact of the latter possessing a corpus luteum and the former not possessing it, he thought that Dr. Stevens's work suggested strongly that it was to the persistence and continued growth of the cells of the tunica granulosa after the disappearance of the ovum from the follicle by dehiscence that we owed that development of sexual characteristics which marked puberty.—Dr. STEVENS replied.

Dr. BONNEY *showed a specimen of a Myoma undergoing* Red Degeneration.

Dr. H. RUSSELL ANDREWS exhibited a Specimen of Bilateral Extra-uterine Pregnancy; (1) Lithopædion, full *term, which had been eight years in the abdomen; and* (2) a fresh Three Months Fœtus.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Patients and Specimens.—Gout.—Radium.—Open air Treatment of Broncho pneumonia in Whooping-cough.—Bennett's Fracture of the Thumb.

A MEETING of this society was held on Dec. 2nd, Professor JOHN CHIENE, the President, being in the chair.

Patients and specimens were shown by Dr. DAWSON F. D TURNER, Dr. W. ALLAN JAMIESON, Mr. J. W. STRUTHERS with Mr A. MILES, Dr. G A. GIBSON, Mr. DAVID WALLACE and Dr. A HILL BUCHAN.

Dr. D. CHALMERS WATSON gave a demonstration on the Comparative Pathology of Gout. The tissues were taken from a young adult fowl which had succumbed after a short illness to naturally acquired gout. Such cases were rare in the records of the disease and, so far as Dr. Watson was aware, no cases had been submitted to a complete histological investigation. The naked eye appearances found at the post-[illegible] the synovia to a cream-[illegible] eaction, deposit of uric [illegible] cular tissues round the [illegible] idespread thrombosis, and smaller [illegible] Microscopic examination areas of [illegible] exudation blocking the showed [illegible] catarrh,' especially in pancrea [illegible] in the large intestine; the ile [illegible], (3) the collecting tubules of the kidney filled with granular leucocytes; (4) pronounced congestion of the liver, the spleen, and the kidneys; and (5) a localised deposit of urate of soda in a lymphatic gland. The appearances were regarded as characteristic of bacterial infection and Dr. Watson emphasised the importance of further attention being devoted to comparative pathology as the line of investigation most likely to advance [illegible] knowledge of the disease; it was specially important to [illegible] but at an earlier period, [illegible] eriological examination of [illegible] d in the intestine recalled [illegible] old-time theory of gout as [illegible] infection which was revived [illegible] pearances in the pancreatic [illegible] having significance in con-[illegible] symptom—gouty glycosuria. [illegible]—Dr. G. L. GULLAND and Dr. T. F S. CAVERHILL made some remarks and Dr. WATSON replied.

Dr. DAWSON TURNER read a paper on Radium. After recalling the steps which led to the discovery of radium he said that the forms of radiation which had been more or less recently made use of in medicine and surgery might be divided into five groups: (1) radiant heat rays; (2) ordinary light; (3) ultra-violet light; (4) Roentgen rays; and (5) radium emanations and rays. The *effluve* or brush discharge produced by high-frequency currents or by static electricity combined some of the properties of the last two. Dr. Turner then described the properties of Finsen and ultra-violet light and Roentgen rays. Radium gave off three kinds of rays as well as a radio-active emanation. It maintained itself constantly at a higher temperature than its surroundings and constantly emitted heat at an estimated rate of about 100 calories per gramme per hour, and was thus in its behaviour in outstanding antagonism to some of the fundamental physical laws. The emanation was of the nature of a luminous gas which could be condensed by intense cold and which imparted radio activity to objects in its path. More than two-thirds of the heating effect of radium were due to this self-produced emanation and one cubic centimetre of it would probably instantly melt down the glass tube which contained it. Pfeiffer and Friedberger had made experiments to determine the germicidal activity of radium. A three days' exposure to 25 milligrammes of radium bromide killed the organisms of cholera, typhoid fever, and anthrax. Though such result was not very encouraging it must be remembered that the Roentgen rays had no bactericidal effect though their beneficial effects in certain diseases could not be doubted. Dr. Turner then referred to the strong action which radium rays had on the human body and to the intractable ulcers which they produced. E. S. London has tested the effect of the rays on mice. Reddening of the ears and blinking of the eyes appeared on the third day; general torpor and paralysis followed with death on the fourth or fifth day. The skin and brain were the parts most affected. The chief physiological effects of radium, so far as at present known, might be arranged in three groups: (1) effects on the skin, producing inflammations and ulcers; (2) effects on the nervous system, producing paralysis and death; and (3) luminous effects produced in the partially blind. The radiations of radium had been tried in various diseases (chiefly those in which the Roentgen rays or Finsen light had been found useful)—e.g., cancer, rodent ulcer, and with distinct benefit in certain cases. The effects produced appeared to be similar to those produced by the Roentgen rays. If it could be obtained in larger quantities it might be employed in practical medicine and so do away with the bulky and costly x-ray installations; patients would be provided with a fragment of radium sealed in a tube which they could themselves apply to the affected part as directed. Radiographs of the teeth or bony walls of cavities could be taken by introducing a fragment of radium inside and placing the negatives outside. Deeply seated growths could be attacked by introducing into them by operation a small tube with the radio-active substance. A few grammes of radium would light up an x-ray screen brilliantly through an inch or more of lead. Dr. Turner also indicated how in many other ways radium might be employed and hoped that further investigation might result in great benefit to mankind. Several photographs taken by the radium rays were shown and specimens of radio-active pitch-blende and bromide of radium were exhibited.

Dr. C. B. KER read a communication on the Open-air Treatment of Broncho-pneumonia complicating Whooping-cough. He said that when he first took charge of the Edinburgh City Hospital seven years ago Sir Henry D. Littlejohn had drawn his attention to the very large death-rate from whooping-cough both in the city and in the hospital, and had expressed the hope that something might be done to reduce it. From that time Dr. Ker had had this object steadily in view and although he had not attained the success that might be desired he had at least had the satisfaction of making a considerable reduction in the death-rate of this most serious complication. Those who only saw whooping-cough in good general practice might not realise how serious it was liable to be in the children of the poor. For the five years ending 1900 the mortality in Edinburgh was 0 48 per 1000 persons living, or, in fact, nearly one-third of the whole zymotic death-rate was due to this disease and was chiefly confined to the lower classes. To endeavour to reduce the death-rate, however, the practical point was to find some method of successfully treating the broncho-pneumonia. It was obvious that in the treatment of an acute or subacute pulmonary inflammation, due almost certainly to the action of micro-organisms and in which toxæmia played a prominent part, everything should be done to maintain the patient's strength and to secure rest. In whooping-cough this was the great difficulty. Dr. Ker had at first tried nearly every remedy in whooping-cough. Belladonna was the only drug which he had much faith in and when pushed freely he thought it of great value in both ordinary and complicated cases of whooping-cough. Inhalations of creasote or eucalyptus he had found to be very disappointing. As regarded the broncho-pneumonia itself leeches were of undoubted value in cases with bad cyanosis. The ultimate routine was to rub the chest with stimulant oils and to apply a jacket of Gamgee tissue. In simple cases a little ipecacuanha wine was given and to the worst belladonna was administered freely. Under such treatment the death-rate still remained appallingly high and roughly speaking two children out of three who developed broncho-pneumonia died. The death-rate of broncho-pneumonia was 71 per cent. in the Edinburgh City Hospital and compared favourably with that of Glasgow—76 per cent. When the idea of putting the patients as far as possible in the open air occurred to Dr. Ker two facts influenced him. One was that he had often seen children who had struggled through a broncho-pneumonia succumb to phthisis or acute tuberculosis, and the other was that a certain number of patients used to contract broncho-pneumonia after admission. He had every reason to believe that the disease was infectious and to put the patients in the open air could hardly increase the death-rate. It would, indeed, probably diminish it by preventing the occurrence of pulmonary tubercle and also by lessening the number of cases which developed in hospital. Although he knew well that many, especially continental, writers had recommended the open air for children with pertussis, the occurrence of a pulmonary complication had been stated to be a special contra-indication of this treatment. Dr. Ker, however, decided to risk this method of treatment and he started with four cots which were placed in a sheltered position but completely uncovered and near the whooping-cough wards. The children were carried out and left for about six hours daily provided it did not rain. The cases were selected from the worst in the wards and indeed were regarded as hopeless. No bad results were noted and there was a very marked improvement in some of them. These cases had been under treatment for some time previously and so had not the advantage of the open air from the start. They therefore did not show the same recovery-rate that was reached later. At a subsequent period Dr. Ker was able to get all the cases in the wards out into the open air for several hours daily and cases admitted with broncho-pneumonia had the benefit of the new treatment from the time of admission. There was no contra-indication to the treatment except convulsions, but these latter patients were seldom kept indoors more than one or two days. The children were warmly covered and the chest was carefully protected with cotton-wool. Screens protected the windward side of the cots which were otherwise well sheltered. The main effects of the treatment were briefly as follows. The whoops were unaffected in number or severity. The appetite was ravenous, the general strength was much improved, and the children slept much better. If from wet weather they were kept indoors for one or two days (which seldom happened) they rapidly lost both appetite and sleep. Convulsions did not markedly decrease, but the whole nervous tone of the children seemed better and they were much less irritable. The temperature was not affected so rapidly as might have been imagined but there was usually a steady improvement in all the symptoms from the day they were first taken out. The improvement was very gradual but both temperature and respirations were considerably lower after a week's treatment. A minor advantage was the rest given to the wards for several hours daily so allowing them to be thoroughly ventilated. Lastly, notwithstanding that one patient developed broncho-pneumonia though out daily and that several had relapses it might be said broadly that broncho-pneumonia of hospital origin became extinct and tuberculous patients did better. The first trials of the treatment commenced in May, 1901, and were continued until Nov. 15th when, although the patients did not suffer, the nurses did on account of the continual dampness. To continue the treatment the sashes of all the windows in a ward of six beds were removed and several new windows were made so that two sides of the room were practically open. In this ward, heated by a good stove, most of the cases of broncho-pneumonia were treated during the winter. During the next summer this formed a convenient room for the worst cases to sleep in, the patients being carried daily into the open air. This treatment was continued till the late autumn of 1902 and again resumed in the summer of 1903. Dr. Ker then gave statistics as to cases and death-rate during the period under review and concluded by saying that of all those treated in the open air of 63 cases death occurred in 19, the percentage rate being 31·1, a great contrast to the 71 per cent. with which the treatment was started. The conclusion arrived at was that whereas two out of three of the patients used to die, now in the open-air treatment two out of three were saved.—Dr. JAMES CARMICHAEL, Dr. CAVERHILL, and Dr. H. HARVEY LITTLEJOHN having spoken, Dr. KER replied.

Mr. MILES and Mr. STRUTHERS contributed a paper entitled "Bennett's Fracture of the Base of the Metacarpal Bone of the Thumb" They stated that it was in 1881 that Professor E. H Bennett of Dublin had directed attention to this common form of injury to the thumb and he maintained that this was the most common simple fracture of the metacarpus. When the end of the thumb was struck the force was transmitted along the phalanges and metacarpal bone and the base of the latter was driven against the trapezium. Inspection of the metacarpal bone showed that there was a marked palmar projection at the base of the bone which carried a large part of the articular surface An antero posterior section through the joint between the metacarpal and the trapezium showed that the articular surface of the metacarpal did not bear equally in the whole extent on the trapezium. In full extension the metacarpal bore on the dorsal part of its articular surface while in full flexion it bore on the palmar part. Further, as the articular surface of the trapezium was convex from before backwards, a force acting in the long axis of the metacarpal would tend to drive the bone on to the back of the trapezium. When, therefore, the metacarpal was driven forcibly against the trapezium, as in a fall on to the point of the thumb, strain must be thrown on the prominent palmar basal projection The trapezium was firmly supported by the scaphoid, trapezoid, and second metacarpal bones and they in their turn by the radius, &c. Consequently the anterior basal projection of the metacarpal bone being relatively weak and badly supported, broke off when a fracturing force was applied in the long axis of the thumb. A continuance of the force would drive the metacarpal on to the back of the trapezium, leaving the anterior fragment with the portion of the articular surface which it carried *in situ*. The signs and symptoms of the injury were: (1) pain along the metacarpal of the thumb, most marked at the base; (2) swelling round the base of the bone and along the shaft, filling the hollow between the extensor tendons of the thumb; (3) very marked limitation of the range and strength of movement of the thumb, complete abduction and complete opposition being impossible; (4) a characteristic abnormal prominence at the base of the metacarpal bone of the thumb posteriorly; and (5) in recent cases the deformity could be readily reduced by extending and abducting the thumb while pressing the base of the metacarpal towards the palm. There was usually marked crepitus associated with this reduction. The deformity returned at once when extension and pressure were removed. In old-standing cases complete reduction might be impossible but grating was often felt due to irregularities in the articular surface. When seen early, or even in old-standing cases when possible, reduction must be effected and the thumb fixed in the reduced position for two or three weeks. A poroplastic splint moulded to the wrist and thumb might be applied for this purpose or the spécial splint recommended by Professor Bennett. Passive movement should be carried out very carefully at first and caution must be given to the patient not to put any strain on the thumb as the anterior fragment might very easily be detached. Manual workers should be forbidden to use the thumb for five or six weeks from the date of the accident. When efficient treatment was carried out early complete recovery was to be expected. Deformity must always remain when patients did not present themselves for some weeks after receipt of the injury. The ultimate results as regards power and range of movement of the thumb, even in cases where considerable deformity remained, were good, though, perhaps, the grip of the affected hand was slightly weaker than was that of the sound side. Mr. Miles and Mr. Struthers recorded 14 cases in all, two being in females and 12 in males; the ages varied from 19 to 60 years. In six of the cases the left thumb was affected, in seven the right, and in one case the side was not stated. Seven cases were due to falls against the thumb, two to striking blows while fighting, one to striking the thumb against a wall in a struggle, one to striking the thumb against a door in the dark, one to heavy bags of sugar falling on the thumb, while in two the cause was not stated. Numerous specimens of the fracture were shown as well as radiograms of the cases exhibited earlier in the evening.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN —A meeting of this society was held on Nov. 20th, Dr. H R. Hutton (Manchester) being in the chair.—Dr. James Taylor showed an anomalous case of Diplegia. A child, aged four years, soon after an operation for an abscess on the right side of the neck, became altered mentally and lost the power of walking Additional symptoms found on examination were occasional regurgitation of fluids through the nose, squinting, absence of knee-jerks, and marked incoördination. Most of the symptoms had passed off under treatment but the degree of intelligence was not yet quite up to the normal standard. The diagnosis made at first was one of diphtheritic paralysis, although there was no history of sore throat. He was now inclined to look on the condition as some other form of toxæmia which had led to alterations in the cerebral cortex.—Dr. G. E Shuttleworth had never seen mental deterioration follow immediately on diphtheria but he recalled one case in which an attack of diphtheritic paralysis was said to be the precursor of mental impairment In the present case he thought that some previous mental weakness had been aggravated by the acute illness —Dr Fletcher Beach regarded the case as one of cerebral diplegia rather than diphtheritic paralysis —Mr. Francis Jaffrey showed a child, aged 18 months, suffering from Multiple Subcutaneous Tuberculous Nodules. The history of the case was that these nodules first appeared when the child was vaccinated at the age of three months. Several of the nodules had softened and burst. He found that vaccination was usually assigned as the cause of these nodules by mothers and therefore advised the postponement of vaccination if any nodules were present. —Dr. C W. Chapman had had a case of similar nodules in an adult which was completely cured by the internal administration of iodoform.—Dr E Cantley recalled a case in a baby ten months old, who died ten weeks later from tuberculous meningitis —Mr. J. P. Lockhart Mummery suggested the excision of one of the nodules to determine whether it was a pure tuberculous affection or a mixed one. —Dr. G E C. Pritchard had seen a case in a woman which had lasted for two years and which was finally cured by arsenic.—Dr. G. A Sutherland showed twin sisters, aged five years, who were the subjects of Idioglossia.—Dr. Leonard G. Guthrie remarked on the strong family likeness which such cases showed, although the particular defects were not the same —Dr. F. Parkes Weber referred to a case under his own care where idioglossia had followed on brain disease in early life. He thought that certainly the motor centres had been affected.—Dr. Henry Ashby (Manchester) did not like the word "idioglossia" and preferred to describe the condition simply as defective speech. Such a condition was common in the special schools for backward children. He thought that one factor which was present was want of attention and that this was coupled with a certain amount of mental backwardness. —Dr. Shuttleworth agreed with the last speaker as to the frequency of defects of speech in backward children. There was an element of laziness about the condition.—Dr. Hutton thought that the trouble was due to defective hearing and defective observation, coupled with a general lack of energy.—Dr. George Carpenter showed: (1) a case of Premature Greyness of the Hair in a female child, aged 11 years; the condition was not inherited and she was in other respects a perfectly healthy child; and (2) a case of General Paralysis of the Insane in a girl, aged 11 years The symptoms dated back more than a year.—Dr. Fletcher Beach had collected notes of 200 cases of this affection and in the majority of these syphilis was present. In children general paralysis usually developed at the time of the second dentition.—Dr. Taylor said that in his experience such cases commenced with gradual dementia and had associated fits, tremors, inactive pupils, and excessive or absent knee jerks. In the majority there was the definite association with hereditary syphilis. The physical conditions in children were the same as in adults but the mental conditions were different—namely, simple dementia in the former without delusions of grandeur.—Mr. Douglas Drew gave an account of three cases of Sarcomata operated on.—Dr. Pritchard showed an infant, aged five months, suffering from congenital heart disease with dysphagia. The difficulty in swallowing appeared to be due to incoördination of the muscles of deglutition. The child was gradually sinking into a marasmic condition although the cardiac murmur was diminishing.—Dr. Cautley read a paper on an Unusual Case of Congenital Hypertrophic Stenosis of the Pylorus. The patient died at the age of 14 weeks and the pylorus presented the usual characteristics but both small and large intestines contained a considerable quantity of normal fœces. While under observation he had gained 13 ounces in weight during one period of two weeks and six ounces during another period of one week. During life peristalsis was noted on one occasion only, the pylorus was palpable, the stomach was moderately dilated, and vomiting was present but was not characteristic. There was not marked constipation and even eight days before death a large almost normal stool was passed. Dr. Cautley pointed out the difficulties of diagnosis in a case of this nature and thought that many such were overlooked. Operation might have saved the child's life but the case was regarded as a somewhat mild form of the condition and later the acute diarrhœa rendered operative interference inadvisable. He thought that the absence of characteristic vomiting in this instance might be urged as an argument against the view that the hypertrophy was due to spasm.—Mr. Clinton T. Dent related two cases of the same disease successfully treated by pyloroplasty —Dr. Alexander Morison showed the Stomach of a Child, aged two months, in which hypertrophic stenosis had been diagnosed and the patient had been admitted for operation. While under observation very little vomiting occurred and only occasionally was gastric peristalsis exhibited. Operation was deferred and the patient was discharged but returned five days later in a collapsed condition with a temperature of 90° F. and died soon afterwards. At the necropsy the pylorus was found to be large, long, and hard.—Mr. J. Howell Evans and Dr. G. de B. Turtle also gave accounts of similar cases which had come under their notice.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Nov. 25th, Dr. J. Nigel Stark, the President, being in the chair.—After an exhibition of specimens a discussion upon Accouchement Forcé, with special reference to the instrument of Bossi, was opened by Dr. Robert Jardine and Dr. T. M. Munro Kerr. Dr. Jardine remarked that the operation accouchement forcé was almost entirely done in the interests of the mother save when the cord prolapsed very early in the course of labour, when the membranes ruptured before labour began and the pressure was detrimental to the child. The operation was most frequently done in the interests of the mother for eclampsia. In pernicious vomiting, heart disease, chorea, and insanity it might be necessary. In cases of complete occlusion of the os Dr. Jardine had performed it upon five or six occasions. The methods of performing the operation were then discussed. The extraction of the child was not touched upon but only the dilatation of the cervix. It was noted that when the cervix was not taken up but retained its full length it was more difficult to dilate than when it was so taken up as found in those who had about reached term, and especially in those where labour had begun. The dilatation might be carried out forcibly or by the aid of incisions. Digital dilatation was mentioned as being the oldest method. If the cervix was soft and yielding full dilatation could be obtained in 15 or 20 minutes. The strictest aseptic precautions had to be observed. A continuous hot douche during the process was beneficial. Chloroform should be administered not only to prevent pain but to assist the relaxation of the cervix. Though the lithotomy position was the more suitable the lateral was also convenient. After dilatation delivery was completed in a variety of ways according to the nature of the case. With regard to dilatation by means of instruments, in some cases if the cervix was very soft hydrostatic bags might be used. This was a slower method and where time was of great importance the method was not very suitable Hegar's dilators were useful to begin the operation with when a finger could not be inserted. Expanding dilators were the most useful and of these Bossi's or a modification was the best. (The various varieties of the instrument were shown.) The eight-pronged instrument of Frommer was recommended. The dilatation must be continuous and slow. From 20 to 30 minutes were required for the full dilatation of the cervix. If carefully used there was very little tearing of the cervix. Dr. Jardine then related the histories of several cases in illustration. The incision method was next reviewed. Dr. Jardine had done this operation quite a number of times in cases of eclampsia. He had practised the making of four incisions in the cervix, further dilatation being obtained by the hand. In some cases the cervix had been subsequently stitched, while in others where there was no hæmorrhage the cervix was left alone; the after results had been quite as good in the latter. In conclusion, Dr. Jardine stated that he thought Bossi's dilator a most useful instrument, but in a case where the cervix was extremely rigid he would prefer the incision method as causing less shock.—Dr. Kerr limited himself to considering the methods of forcibly enlarging the cervical canal. He described briefly the methods of manual dilatation, giving his opinion that by this method safely to dilate and to extract a child when the cervix was not taken up required on an average 40 minutes in a multipara and 60 minutes in a primipara. It was on the whole the safest but certainly was the slowest method. As regards dilatation with Bossi's or Frommer's dilator, he came to the following conclusions: (1) when the cervix was obliterated and the os would admit the dilator without difficulty dilatation could be carried out in about 25 minutes and there would be little or no laceration of the cervix; (2) in cases where the pregnancy had advanced to or near term, even although the cervix was not obliterated, dilatation might be accomplished with comparative safety to the cervix provided care, time, and patience were expended in the operation; and (3) in cases of early pregnancy with the cervix unobliterated there was decided risk of extensive lacerations even although the greatest care was taken. Dr. Kerr then considered the methods of enlarging the canal by making deep incisions and gave examples to show that the child could be extracted in four minutes. He also described a case of Cæsarean section upon Dührssen's method performed with success at the fifth month of pregnancy.—Dr. W. L. Reid had met with few cases where manual dilatation had failed but the method was not rapid.—Dr. W. B. Armstrong, Dr. J. W. Russell, and Dr. G. Scott MacGregor having spoken, Dr. A. MacLennan mentioned that though he had had no experience of the Bossi instrument he had performed Dührssen's operation upon a primipara at full term for a rigid cervix. The suturing of the anterior incision had been readily performed without assistance in a private house.—Dr. Gardiner thought that the general practitioner would prefer to use Bossi's dilator to performing vaginal Cæsarean section, and the President having remarked that there was a danger in these days of midwifery becoming too meddlesome Dr. Jardine and Dr. Kerr replied.

THERAPEUTICAL SOCIETY.—A meeting of this society was held in the Apothecaries' Hall, Blackfriars, on Nov 24th, Sir William Thiselton-Dyer, the President, being in the chair.—Dr. R. B. Wild of Manchester read a paper on the Pharmacology of the Saponins, illustrated by diagrams and tracings, and said that the saponins were bodies found in several drugs, as senega, sarsaparilla, digitalis, and quillaia bark. They had the property of forming emulsions with water but were poisonous hypodermically. Even in very diluted doses they caused decided contraction of the blood-vessels and a frog's heart gave small, quick, regular beats without becoming thoroughly relaxed, but with a stronger solution it stopped quickly in a contracted state. First, it was believed that quillaia bark was often used to form an emulsion, even when not prescribed, but if there was any lesion of the stomach or intestines this might become dangerous; secondly, it was possible that all these drugs containing saponins might, like sarsaparilla, be useful in tertiary syphilis, but there was reason to believe that sarsaparilla deteriorated rapidly by keeping and old samples might be entirely inert; and thirdly, saponins were not antagonistic to digitalis, but resembled it in their power of contracting the blood-vessels and the cardiac muscle, but they did not cause the slowing of the beats and the prolongation of the systole as did digitalis.—Dr. Soper said that, from this most interesting paper, it would appear that saponin acted similarly to adrenalin.—Dr. Sainsbury thought that saponin was similar in its action to digitalis and might be useful in heart disease but that it certainly ought not to be used as a mere emulsifying agent.—Dr. Wild, in reply, said that saponin had not the local action of adrenalin and it differed from digitalis inasmuch as the blood pressure was actually diminished after its use from the heart becoming weaker, although the blood-vessels were contracted by it.—The President thanked Dr. Wild for his most interesting and important paper and said that the toxic properties of the saponins had not been fully appreciated or drugs containing them would not be so often employed as emulsifying agents.—Professor Wyndham Dunstan, F.R.S., gave an account of the chemical investigations now proceeding at the Imperial Institute at the instance of the Government of India of the various Indian Aconites and their Alkaloids. The properties of the three distinct alkaloids which had been isolated from the three characteristic aconites known in European medicine were first noticed: aconitine from aconitum napellus, japaconitine from aconitum japonicum or Fischeri, and pseudaconitine from the aconitum ferox usually found in European medicine. These three alkaloids, though chemically different, belonged to the same type and exerted a physiological action which only differed in degree. The Indian aconites, varieties of aconitum napellus and aconitum ferox, which had so far been examined by Professor Dunstan and Mr. Andrews, had furnished pseudaconitine and two new alkaloids which had been named indaconitine and bikhaconitine. In chemical properties and in physiological action and toxicity the new alkaloids closely resembled pseudaconitine. The botany of these aconites had been studied at Kew by Dr. O. Stapf and the physiological action of the alkaloids had been obtained from them by Professor Cash. The aconitum palmatum of India has furnished a new non-poisonous alkaloid to which the name of palmatisine had been given. It was closely allied to the alkaloid atisine derived from another Indian species, the aconitum heterophyllum.—Dr. Stapf of the Royal Gardens, Kew, said that the aconites had long been known as most powerful poisons, but the plants had not been accurately determined till quite recently, when Professor Dunstan found that different alkaloids [illegible] aconite all called aco[illegible] ascertained that the [illegible] Sikkim were deri[illegible] from Kumaon were [illegible] and those from Garhwal from the aconitum elcinorrhizum; the aconitum spicatum yielded bikhaconitine, the other two species pseudaconitine. In the Punjab the aconite roots were brought from the mountains north of Peshawar and these were derived from the aconitum chassnanthum, giving a new alkaloid, indaconitine. The aconitum napellus had not been found in India. Dr. Stapf further said that a non-poisonous aconite gave the Judwar Kutai, the zedoary of the ancients, the tubers of which closely resembled those of aconitum heterophylloides found in East Nepaul, but there were at least 20 species of aconites in India.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society took place on Nov. 26th, Mr. Thomas Richmond, the President, being in the chair.—Mr. John Carswell read a paper on Alcohol and Preventive Medicine. Mr. Carswell referred to the diminution of the death-rate in Glasgow during the last 30 years. This diminution, he said, had occurred in every district with the exception of two—viz., Brownfield and Cowcaddens. The three worst districts 30 years ago were Bridgegate and the Wynds, High-street and the closes east of High-street, and High-street and the closes west of that thoroughfare. These three districts had largely diminished in population since, while the populations of Cowcaddens and Brownfield had not diminished. Comparing these five districts Mr. Carswell pointed out that the character of the population had improved in all the districts which showed a lower death-rate and had declined in the [illegible] death-rate. He pointed to [illegible] death-rate which followed [illegible] gate and clearing out of the "rookeries." The saving of life from zymotic diseases was, he said, but a small part of the work resulting from proper sanitary control and he pointed to the death-rates of 1891 and 1900 which showed a reduction of 0·318 per 1000 from zymotic diseases, while the reduction in the death rate from respiratory diseases had amounted to 2·372 per 1000. Referring to the persistently insanitary districts of Glasgow Mr. Carswell considered that there was some reason for their lack of improvement which required elucidation. [illegible] which kept the poor together; [illegible] habits of the people or it m[illegible] which induced them to huddle together. They were forced into the worst districts, having been ejected from better localities either from inability to pay the rent demanded or on account of disorderliness. He believed the crux of the position lay in the one word—poverty. He recognised two classes of poverty (1) primary poverty, in which there was absolute insufficiency of means, and (2) secondary poverty, which was induced by misfortune, ignorance, drink, and vice. Speaking on the part alcohol played in the matter, Mr. Carswell was very optimistic; acknowledging that drunkenness caused poverty, failure of nutrition, and serious disorganisation of mind and character, he did not believe that the craving for alcohol was inherited or that alcoholism in the mother could produce serious mischief in the unborn infant. He considered that the doctrine that the nutritional defect in the child was caused by alcoholism in the parents was very disheartening and he did not believe that acquired vices were transmitted to the offspring. He instanced the improvement of the children of alcoholics by better environment. Proper care in childhood was, he believed, a factor in checking the degeneracy of manhood. Reduction in the death-rate had not, he thought, favoured an increase in adolescent insanity. He advocated increased interest in the care of children and would favour the establishment of a "child welfare society." He pointed with satisfaction to the good effect of supplying children of the poor with food while attending school. Mr. Carswell deplored the "blank apathy" in the lives of the poor and hailed with delight the advent of any demagogue with power to awaken conscience in the poverty stricken. He thought that this was the way by which the poor might be made to abandon drink and to awaken to fresh interests, their own included.—Considerable discussion followed and was taken part in by Dr. A. K. Chalmers, Mr. A. Miller, Dr. D. Macgilvray, and Dr. T. Forrest.—Mr. J. V. Wallace thought that the improvement in the condition of the people was due not so much to sanitary science as to the spread of education.—Dr. Carstairs C. Douglas failed to see how any amount of erudition could conduce to longevity when there was a cesspool under the floor of the living room.—On the motion of the President, Mr. Carswell was thanked for his address.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Dec. 3rd, Dr. W. Macfie Campbell being in the chair.—Mr. F. W. Bailey read a note on the History of the Stethoscope and showed an example of Laennec's instrument.—Dr. K. A. Grossmann gave a communication on the Occurrence of Double Focus in the Human Lens as found by him in five patients during the last two years. The lens was divided by a sharp line into two areas of different refraction, in four out of the [illegible] The nature of this hitherto unde[illegible]hods employed in examining it [illegible] by a number of diagrams and lantern slides; two of the patients were shown, a man, aged 20 years, and a female, aged 45 years. Dr. Grossmann also demonstrated a patient in whose left eye the ocular conjunctiva was the seat of a number of large papillomata without any catarrhal or other discharge.—Mr. G. P. Newbolt read notes on Osteotomy of the Upper End of the Femur, illustrating his remarks by lantern slides. He laid stress upon the following points: (1) all cases of marked tuberculous disease of the hip should be treated on an abductor frame in order to avoid the adductor deformity almost invariably present; (2) in all cases of ankylosis or of short strong fibrous union with deformity osteotomy of the upper end of the femur should be performed; (3) Adams's operation of sawing through the neck of the femur, when present, was to be recommended, when absent transtrochanteric osteotomy might be done; Gant's operation—infratrochanteric osteotomy—was not so good though it avoided sawing through a big mass of bone; and (4) open incision with removal of the upper end of the bone was sometimes necessary; tenotomy or rupture of the adductors was often needed in addition. Septic sinuses about the hip offered no bar to osteotomies in their neighbourhood.—Dr. J. C. M. Given reported a case of Hyoscin Poisoning.—Dr. C. A. Hill read a note upon Enlargement of the Thyroid at Puberty. Two cases were narrated in which pressure symptoms arose. Both improved under the exhibition of thyroglandin.—The various communications were commented upon by Dr. Campbell, Mr. Newbolt, Mr. T. C. Litler Jones, Dr. W. B. Warrington, Dr. Given, Dr. A. S. F. Grünbaum, and Dr. J. J. O'Hagan.

ABERDEEN UNIVERSITY MEDICAL SOCIETY.—A meeting of this society was held on Dec. 4th.—Mr. F. Anderson read a paper on Diabetes. After discussing the various causes he came to the conclusion that the only satisfactory explanation was that diabetes was due to pancreatic disease. An apparently normal pancreas showed on microscopic examination degeneration of the islands of Langerhans in a good many cases. In treatment diet was of the utmost importance and for the first few days ought to be directed to the removal of glycogen from the liver. Thereafter on a special diet in which milk largely predominated the patient's urine should show no increase in sugar. Exercise of all sorts was necessary in suitable cases to keep the patient "fit" or massage might be resorted to were exercise not permissible. The best drug was liquor morphinæ hydrochloratis in big doses of 110 minims three times a day. In one case 150 minims three times a day had been given. Uranium nitrate had also some reputation.—Mr. J. S. Gray followed with a paper on Blood-letting. Beginning by a rapid survey of its employment in ancient times he went on to its applications at the present day. Its uses now were mainly limited to relieving local inflammation, mitral incompetence, acute pneumonia, and the exanthematous fevers, but probably at no distant date a wider field of application would be found for it.—Interesting discussions followed each paper.

EDINBURGH ROYAL MEDICAL SOCIETY.—A meeting of this society was held on Dec. 4th, Dr. H. D. Shepherd being in the chair.—A dissertation on Puerperal Eclampsia was read by Dr. B. P. Watson. He described the clinical varieties of the condition and briefly discussed the differential diagnosis, the causes of death, and the post-mortem appearances On the question of etiology he mentioned as inadequate the theories that uræmia, cerebral anæmia, and mere nervous excitability were the causes of the disease. The most plausible theories were those of Bouchard and Nicholson, that of Bouchard being that the disease was really an auto-intoxication, while Nicholson believed that inadequacy of the thyroid secretion was the primary cause of the disease. This latter theory, Dr. Watson held, would explain the symptoms in at least some of the cases; and he laid stress on the use of thyroid extract for prophylaxis and treatment.—Dr. D. C. L. Fitzwilliams read notes of a case operated on for Gall-stones on which a subsequent gastro-enterostomy was performed.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on Dec 3rd.—Dr. Charles H. Melland gave a lantern demonstration of micro-photographs illustrating the Characters of the Blood in Health and Disease. The first series of slides showed the elements of normal blood. These were followed by the various types of anæmia and in this connexion the progress towards recovery in pernicious anæmia was demonstrated. Leucocytosis and the different varieties of leucocythæmia and finally the parasite of malaria were shown.—Mr. G. W. Malim and Mr. W. Stanwell expressed the thanks of the society to Dr. Melland for his demonstration and congratulated him on the beauty of his preparations.

Reviews and Notices of Books.

Laboratory Studies in Tropical Medicine. By C. W. DANIELS, M B Cantab., late Medical Superintendent of the London School of Tropical Medicine, Director of the Institute for Medical Research, Federated Malay States. London: John Bale, Sons, and Danielsson, Limited. 1903 Pp. 384. Price 15*s*. net.

"THE object of this work is to assist practitioners in the tropics in the application of simple laboratory methods to the practice of medicine." The author of the treatise brings to the fulfilment of the task that he has thus set before him the special qualification of a far-reaching experience gathered from several tropical countries. How well he has succeeded will be gathered from this brief review. The worker in the tropics, unless he resides, perchance, in the one or two presidency towns, will have no equipped laboratory to resort to, but Dr. Daniels in his opening chapter tells how this deficiency can be remedied. Minute details as to the working of the microscope are laid down; even such minutiæ as, for instance, the proper treatment of cover glasses are not forgotten. Next we find the various methods for the preparation of blood films, fæces, mosquitoes, and bacteriological material adequately described. The points with regard to post-mortem examinations that are peculiar to the tropics are narrated; minute directions as to the preparation for the examination of mosquitoes are then given, whilst it is well pointed out with regard to stains and other reagents that these should after importation in solid or concentrated form be kept previously to use in these conditions.

We next come to the investigation of the blood, the most important subject of all in the tropics. The methods of examination of fresh blood are fully set forth, that of dried films and their fixation is detailed, and the best method of staining is pointed out. Dr. Daniels next passes on to the detailed examination of the various parasites found in the blood, such as the protozoa of malaria, the trypanosomes, the bilharzia, and the filaria. With regard to malaria, it may safely be said that no clearer or more lucid exposition of this subject is extant, whilst the same thoroughness and exposition of detail characterise the account of the examination of the other parasites, the whole subject being completed by the information given as to the methods for demonstration of the presence or absence of the specific agglutinins causing the agglutination of the corresponding micro-organism. Dr. Daniels has enlisted the services of Mr. Theobald in the description of the various diptera; the reader is taught next how to prepare the mosquito for demonstration, whilst its anatomy and the methods of its dissection are minutely given. The next chapter deals with the demonstration of the development of malaria parasites in mosquitoes. Their eggs and larvæ are detailed and the subject is concluded with an account of the excellent mosquito-box devised by Dr. Louis Sambon for transmission of infected mosquitoes.

The matter of pigmentary deposits is fully entered into, as are also the subjects of "cloudy swelling," "fatty degeneration" (so important a factor in many tropical diseases, such as yellow fever and ankylostomiasis), "amyloid degeneration," and "fibrous degeneration." The examination of the fæces receives complete notice and especially valuable is the description of the various ova of parasites; some excellent differentiating points of the various species met with are given. In the next chapter the facts relating to the examination of the urine are dealt with. A very useful exposition follows on the subject of bacteriology in the tropics and in this chapter we find the difficulties experienced by workers in those regions on this subject lessened as much as possible. The practical experience of the author is well shown by his statement concerning the difficulty attending the making of nutrient broth in the tropics and he recommends meat extracts as efficient substitutes. The whole of this part of the subject is treated in a manner which will be found of great value to anyone engaged in investigating bacteria in hot climates. The concluding chapter of the work is taken up with the means of measuring the various eggs, parasites, and normal and subnormal cells. A useful appendix of the instruments and reagents necessary for laboratory work completes the volume. Finally we may draw attention to the excellent plates illustrating the quartan and tertian parasites, the various corpuscles of the blood, the trypanosomata, the spirillum, and the amœba coli.

We consider this work a most valuable addition to medical literature. There is no "padding" in its pages but each chapter reveals the large experience of the author in the subjects of which he treats. The London School of Tropical Medicine sustained a great loss when Dr. Daniels left it to take up the post of director of the Institute for Medical Research in the Federated Malay States. In this case most assuredly what was the loss of the school was the gain of Malay.

Post-mortem Pathology: A Manual of Post-mortem Examinations and the Interpretations to be drawn therefrom. By HENRY W. CATTELL, A.M., M.D With 612 Illustrations. London and Philadelphia: J. B. Lippincott Company. 1903 Pp. 372.

THIS work is a practical treatise on the methods of performing post-mortem examinations and includes some account of the morbid conditions of the organs usually found. The author in his preface states that it has been written "for those who ought to make autopsies but do not, and for those of whom such investigations are required, as medical students, hospital interns, and coroners' physicians." It is obviously the outcome of a very large practical experience of post-mortem work and those sections of the book dealing with instruments, technique, the removal of organs, and the preparation of specimens are useful, practical, and clear. The general methods recommended and described are those used by most German and English pathologists, and the author acknowledges his indebtedness to Orth's "Pathologisch-Anatomische Diagnostik" and to Nauwerck's "Sections-Technik." The descriptions of routine incisions and manipulations are full and lucid and are most lavishly illustrated; thus there are nine large illustrations of the method of removal of the brain and seven of removal of the spinal cord. The author insists on the importance of systematic examination of organs and of descriptive records of the appearances observed, and we quite agree with him that printed forms are cramping to description, though often useful. The chapter devoted to the description of post-mortem instruments and the methods of using them is good, while that dealing with the care of the hands and the treatment of post-mortem wounds contains some useful hints and warnings. In the chapter on the examination of the exterior of the body the author suggests that when surgeons remove organs from patients they should tattoo on the skin near their incision the initial letter of the part removed followed by the sign minus, for the information of other surgeons under whose care the patient may subsequently pass, or, perhaps, of the pathologist—a suggestion which we imagine will hardly commend itself to surgeons or to their patients. There is a chapter on comparative post-mortem examinations, with directions as to the methods of examining the viscera of horses, oxen, swine, dogs, and cats.

The chapters dealing with the pathological conditions of the organs are disappointing when compared with those devoted to methods. The descriptions are in nearly all cases brief and scanty, and in many comprise little more than mere lists of the conditions affecting the organ under consideration. There are no illustrations of morbid organs and we cannot but feel that some of the illustrations so lavishly allotted to the methods might with great advantage have been used for this purpose. Moreover, at the commencement of the account of each morbid condition is given a numbered list of causes considered rather from the clinical than from the pathological standpoint, which seems somewhat unnecessary in a work of this kind. The brevity of description of diseased organs seriously detracts from the value of the book. Thus, for example, only one page is devoted to the description of all the varieties of pulmonary tuberculosis, and from too much conciseness incomplete and misleading statements arise; for instance, in the description of lobar pneumonia we find, "Lobar pneumonia occurs in adult life, in males, in infectious diseases, in alcoholism after exposure to cold and wet"; and again: "Usually the right lung is affected, the process being confined to the lower lobe," from which it might be concluded that pneumonia was unknown in women and children and never attacked the apices.

The literary style cannot be commended and the book shows evidence of hasty preparation. Repetition often occurs, sentences are frequently clipped to mere phrases, and misstatements or misprints are not uncommon, among which may be mentioned "the secretion of the thymus," "caput of Medusa," and "chronic involvement of the stomach" for what is presumably "chronic engorgement." "Secant" for pathologist is new to us, while the frequent use of the word "posted" to indicate the performance of a post-mortem examination, though possibly a convenient colloquialism, as the author avers, is not elegant and, to say the least, is ambiguous.

The illustrations are good and it is to be regretted that the descriptive sections of the book are not up to the excellent level of those devoted to pathological methods.

LIBRARY TABLE.

Aids to Physiology. By PEYTON T. B. BEALE, F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1903. *Pp.* 239. Price 3*s* 6*d*.—This little book is founded on the "Aids" written many years ago by Professor B. Thompson Lowne whose work though, like the present one, small in compass contained in a compressed form a considerable quantity of information. Mr. Beale has made many minor additions in nearly every chapter but especially in that devoted to the nervous system, making it more in harmony with recent advances but not materially altering the character of the work which will be found a useful reminder of many facts to the student who has diligently attended the lectures and the demonstrations that are now given in every medical school. It should only be used as a reminder and should not be regarded as a book from which physiology can be learned even for an examination.

Twentieth Century Free Trade: A Non-political View of the Question. By E. H. SKRINE, B.A. Oxon., Planter, Trader, and Agriculturist. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1903. *Pp.* 27. *Price* 6*d*.—The author of this pamphlet, which, he states, has reached a second edition, calls our attention especially to the portions dealing with his censorship of tea. He deprecates the over taxation of a "necessary beverage—tea" and thinks that the Government should have appointed "one or two" tea experts as censors with a free hand to examine any lots of tea of suspected quality imported and to veto the landing of them if pronounced unfit for consumption, so that the medical outcry against tea might have become "devoid of foundation." Whether tea is a "necessary beverage" is questionable, but we are of opinion that all foodstuffs intended for human consumption and unfit for it should be effectively condemned as soon as possible. Thus we are mainly in accord with Mr. Skrine but we think that some of his other statements require modification. For instance, he states that "tea as an industry is practically limited to India and Ceylon." With this we cannot agree. So far as the United Kingdom is concerned, of the six pounds per head per annum consumed little more than one-third of a pound is Chinese; nevertheless, there are many persons to whose taste the delicate and distinctive flavour and quality of China teas appeal. In a report to the House of Commons in 1818 it was stated that millions of pounds' weight of sloe, liquorice, and ash-tree leaves were every year mixed with Chinese teas in England, but *tempora mutantur nos et mutamur in illis*. We may digress to say that Mr. Skrine advocates the establishment of a revised and equitable schedule of food taxes which shall remain unaltered but, as we have said, times change and necessities change, and we would ask the author his own question, "Is not this world one continuous change and revival?" The author states that "excess of wealth without specific duties to employ that wealth on becomes in the hands of a weak or idle man as much a disease as fat in the body is a disease." But then we are not willing to allow that fat in the body is always a disease. A writer in Quain's dictionary says, "It is an excellent packing material in the body, being light, soft, and elastic." We can perhaps guess what Mr. Skrine means but in a discussion of this kind terms should be carefully chosen to avoid confusion. For instance, Mr. Skrine also asks on p. 10, "Has the last remnant of protection been banished from our fiscal system when we have just seen reimposed and again withdrawn a war tax on the bread of the people?" On p. 13 he says, "The late Boer war duty did not affect the price of the loaf at all." It is difficult therefore for us to see how it taxed the "bread of the people." Reverting to the subject of tea, we will not say, however, that a discussion of the duty on tea is unimportant as it was the duty imposed on tea in America in 1767 which was one of the causes of the revolutionary war which ended in the independence of the United States.

Knowledge Diary and Scientific Handbook for 1904. London: *Knowledge* Office. Price 3*s.* net.—This excellent diary and scientific handbook is now in its fourth year of publication and will be found of great use by students and workers in almost any branch of science. The size of the book is six inches by nine inches and a blank page is apportioned to each day of the year. Space is provided for monthly notes, letters received and despatched, cash account, and memoranda, as well as for an index to the diary. The letterpress consists of practical articles by competent writers on astronomy, microscopy, natural history, meteorology, and optics. Celestial phenomena are adequately dealt with and there are a number of maps showing the night sky for each month of the year and the paths of the planets, with a descriptive account of the constellations and the principal stars. Not the least useful part of the book consists of the tables relating to money, measures, specific gravity, and such like things, items which the busy man sometimes forgets for the moment. A photoprint of Charles Darwin forms a frontispiece.

Diaries for 1904. John Walker and Company, Limited, Farringdon House, Warwick-lane, E.C.—These well-known
diaries are an *édition de luxe* without being expensive.
the diffse for 1904 are quite up to the usual high standard of
parasite oance. The Golfer's Diary is likely to be useful to
Mr. W. Stan·ho take an interest in this popular pastime. It
Melland for hi a concise form the rules and etiquette of the

JOURNALS AND MAGAZINES.

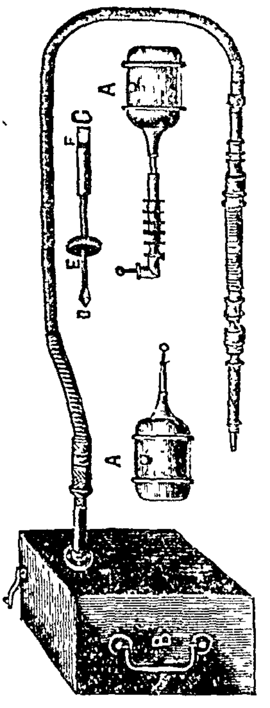
The Practitioner.—The December number of this magazine starts with a most attractive contribution from the pen of Dr. G. H. Savage. This is a lecture on the Mental Disorders associated with Decay and, like everything that Dr. Savage writes, it is full of interesting and *apropos* cases and anecdotes. Dr. Savage has the rare gift of presenting lightly the teachings that have only been gained by long and deep experience. His readers are nearly as much entertained as they are instructed. The *Practitioner* this month has other admirable articles. Mr. B. G. A. Moynihan discusses the question of Operation in Cancer of the Stomach. He quotes many foreign statistics. The conclusion arrived at is that ten months' longer life may be expected from gastrectomy than from gastro-jejunostomy. Articles by Dr. G. F. Still upon Diseases of Children, Dr. A. S. F. Grünbaum on Immunity, and Mr. Herbert S. French upon Clinical Examination of Gastric Contents are all worthy of perusal.

Pall Mall Magazine.—The Christmas number of the *Pall Mall Magazine* contains a great deal of readable matter if no particularly striking contributions. "Blue Roses," by Netta Syrett, is a pretty and humorous fairy story, with excellent illustrations by G. N. Sime. The Rebuilding of London, by "C. M.," illustrated by H. Fitton, forms an interesting lament over the hourly increasing destruction of old London, while the description of Lansdowne House, by E. M. Jessop, reveals the interior, with the agency of good photographs, of one of the stateliest of English domestic palaces. A causerie by W. L. Alden and stories by Fielding Hall and A. A. Vachell make for entertainment, but stories by G. B. Burgin and H. B. Marriott-Watson are not so happy.

New Inventions.

A NEW PERFORATOR FOR SURGICAL AND DENTAL OPERATIONS.

THE instrument of which we append an illustration was invented by M. S. Bercut who is surgeon-dentist to the École Polytechnique, Paris, in collaboration with M. A. Donat who was formerly a pupil at the School of Horology at Cluses. It was exhibited at one of the November meetings of the Society of Sciences in Paris by M. Lannelongue. The essential parts of the apparatus are a metallic box containing a clock-work movement which is made in two forms A and B, A being the smaller and more portable. To this can be adapted a stem C which will carry drills of various kinds, one of which is shown at D, fitted to a stem, E F, a small saw, polishing brushes, or discs. The form B being larger and more powerful than A carries an elastic adapter to which the drill or other tool can be fitted. So rapid is the rotation and so powerful is the action of the drill that the mastoid cavity, the frontal sinus, or the maxillary sinus can be opened in two seconds, while the cranial cavity can be opened in six seconds. Owing to this rapidity no anæsthetic other than a purely local one is necessary, while the extreme portability of the apparatus makes it easy for the dentist or the surgeon to operate at the patient's own house.



THE LANCET.

LONDON: SATURDAY, DECEMBER 12, 1903.

Medical Science and Imperial Responsibility.

To the man who thinks, to the man who reads the lesson of the world's growth aright, conquest means something more than the din of war, the fall of cities, and the guerdons of victory. The processes by which a civilised state makes for itself "the bounds of empire wider still," he knows to imply not merely the organisation of armies, the exposition of military genius, or even the successful propagation of religious creeds or the arrangement of advantageous political and commercial conditions. He feels that conquest means more, much more, than all these things. The acquired territories can only be brought into moral and material line with the central government if the new citizens can be helped to enjoy the natural gifts of their soil by being helped to combat its natural drawbacks. Capture must be made of more than cities. The expansion of territorial limits, the subjugation of hostile or savage states, is only part of the enlightened man's ideal of conquest. Capture and subjugation must be attempted of the physical conditions of the annexed land.

Three addresses have been recently delivered to important audiences in which this broad conception of conquest is well illustrated. Sir PATRICK MANSON, at the London School of Tropical Medicine; Professor RONALD ROSS, at the opening of the winter session of the Medical School of Anderson's College, Glasgow; and Dr. F. C. E. TRIBE, at the Egyptian Government School of Medicine, Cairo, all spoke with eloquent appreciation of the true meaning of empire. Professor ROSS, on the fostering ground of DAVID LIVINGSTONE and WILLIAM MACGREGOR, delivered an address worthy of their examples, his words being directly calculated to quicken the enthusiasm of his audience whether he was appealing to the unlearned imagination of medical students or to the deliberate consideration of mature practitioners. He claimed good reason for regarding the relation of medical science to the spread of empire as the paramount medical theme of the moment and he justified his claim by cogent argument. We are at a stage in the world's affairs when the great civilised nations, feeling the effects of crowding throughout the temperate regions of the earth, are overflowing into others. The current draws with it a large number of medical men whose duty and concern it is to study the novel conditions of life. They have to point the way in which perils of environment, menacing existence itself, may be overcome so that life may be rendered in the first place possible, next safe, and lastly comfortable. The new country, where the first and the second of these two things have been accomplished, may be considered to be conquered in the fullest sense, which is another way of saying that if science does not lend her helping hand the skill of the general, the tact of the diplomatist, and the energy of the trader will all fail to result in effective empire. The thing is so obvious and yet so little, so very little, realised by the world. What is the most powerful enemy of armies? With the episodes of the South African campaign fresh in our memories, a campaign in which not a few lives were lost by regrettable incidents in the field, we need scarcely ask the question. Even with the comparatively enlightened medical measures of to-day the proportion of victims claimed by disease makes destruction at the hands of a human enemy trivial. To take a still broader view, what is it that has kept the tropical zone of the world, comparatively speaking, barbarous? Why are tropical America, tropical Africa, and much of tropical Asia not open to the advent or the benefits of civilisation? Africa, with a trade wind to its very shores, with valuable natural resources, and with gigantic fertile areas to set against its sands and morasses, long ere this, said Professor ROSS, should have been a second India. The prosperity of India is not, we fear, enormously in evidence, but at any rate there is no doubt that Central Africa, instead of being the darkest land on the face of the earth, would have been peopled, cultivated, and civilised up to something approaching the standards of other countries had it not been found impossible for the white man to live there in comfort and safety and very often impossible for him to live there at all. Disease has kept back the clock of progress. The condition of Egypt illustrates the reverse of this story and affords a signal proof of the fact that unless science aids the conqueror their labour is but lost who annex new lands. Of course, Egypt is not truly tropical or a naturally unhealthy country, but it is, to put it mildly, a hot district where till lately sanitation was not practised. Dr. TRIBE, in his address at the Egyptian Government School of Medicine, was able to speak forcibly of the results that had followed in the land of the PHARAOHS from attention to the principles of medical science. In Egypt medicine is seen to be the recognised support of progress. The spying out the land for its physical and medical disabilities has been done, the advance work necessary to render existence possible for the main armies of civilisation has been carried out, and in Egypt we find science, especially medical science, maintaining these armies by reducing the losses inflicted upon them by epidemic disease. Cholera and small-pox rather than malaria and yellow fever are the foes to be feared, and science has proved its ability to offer effective resistance.

The third address, which brings before us the full responsibility of our imperial system, is that which was delivered at the London School of Tropical Medicine on Monday last by Sir PATRICK MANSON. In summarising the achievements of the school Sir PATRICK MANSON showed that the education of a large band of eager students in the problems of tropical pathology has had already a powerful influence upon the position of the mother country in relation to her colonies. "Where two or three men," he said, "took a languid interest in tropical disease some five or six years ago, a whole army of eager investigators has arisen, mainly composed of men educated or inspired by the London and Liverpool schools of tropical medicine." Taking grave risks, and inspired by love of humanity as well as by honourable personal ambition, these students have gone forth into all parts of the world, spreading with zeal the knowledge that they have and acquiring with greed more knowledge as they go. We have recorded from time to time their successes, and proofs of their arduous work can be found in many places in our columns this week. It is not easy, in fact or imagination, to set a bound to the value of such labours, and the medical profession as a whole has seen with pleasure that the nation is beginning to appreciate these labours at their right price. The public is now alive to the part that is played by scientific medicine in welding together the empire.

◆

Natural Science and the Medical Profession.

THE question which for the last two or three years has been debated between the General Medical Council and some of the licensing corporations—the question, that is to say, of the amount of preliminary scientific training required by medical students, and of the stringency of the examinations by which the consequent attainments should be tested—is no doubt one of great importance in relation to the subsequent acquirement and application of distinctively medical or surgical knowledge; and it is chiefly from this point of view that it has so far been considered. The Council, in our opinion rightly, regards both the accepted modes of instruction and the accepted standards of proficiency as altogether insufficient, and the corporations, in the face of the reports recently made to the Council by its appointed inspectors, can hardly dispute the soundness of this conclusion. The difficulty of so acting upon it as to bring about an effective reform seems to depend mainly upon the tendency of the corporations to resist what they regard as the dictation of the Council, and to assert their own right to decide upon the conditions under which their qualifications shall be granted. The Council, on the other hand, conceives that its statutory right of reporting an insufficient examination to the Privy Council is one that should be exercised on fitting occasions, even if only to obtain relief from the responsibility of yielding a tacit assent to conditions of which it disapproves. On the question whether the present occasion was a fitting one, whether, that is to say, the Council should ignore the expressed intention of the corporations to improve the impugned examinations, and should deal according to statute with the defects shown to be existing, or should wait to see to what extent the promised improvements were of practical utility, the Council was so equally divided that the amendment in favour of waiting was only carried by 16 votes to 12, with two absentees, and was only carried as a substantive motion by 14 votes to 13, with three absentees. It may fairly be inferred that the patience of the Council is nearly exhausted, and that, unless the promised reforms, both in the examinations and in the methods of instruction leading up to them, prove both speedy and effective, we shall witness the deplorable spectacle of litigation before the Privy Council in respect of alleged deficiencies in the conduct of medical education or, more correctly, in the conduct of certain preliminary studies, the value of which the public is becoming year by year more and more abl correctly to appreciate.

The controversy so far has turned in great measure upon the assumed or asserted rights of the chief parties to it, but it is, nevertheless, of a much deeper and more permanent interest in relation to the position of the profession in the estimation of the public. We once knew a clergyman who, after residing many years as a Fellow of his college, at last accepted a living in the country. On taking possession he found that his predecessor had let off most of the glebe to a neighbouring farmer, but had retained in his own hands a small portion, for the cultivation of which this same farmer was accustomed to supply implements and labour. The farmer called upon the new rector and obtained his consent to the continuance of the described arrangement; but having done so he still lingered, after the fashion of one burdened by thoughts which he hesitates to impart. At last, taking his courage in both hands, he announced that WILLUM DICKER would come next morning to plough the four-acre close, and thus continued his discourse: "WILLUM will be very proud if your reverence were to go through the close and pass the time o' day; but whatever you do, sir, don'tee say nothin' to WILLUM about ploughin' or sowin'. You see, sir, he hath bin ploughin' and sowin' all his life, and he do know all about it, and if your reverence was to say a word he'd see in a minute as you know nothin' about it, and if WILLUM once gets to think as you know nothin' about ploughin' or sowin' he'll never take heed to your sermons." *Mutato nomine de medico fabula narratur.*

In respect of scientific knowledge the present generation has witnessed a change which might almost be described as a revolution; and it is very doubtful how far the character and extent of this change have as yet been realised either by the medical corporations or by medical practitioners. Only a few years ago medical men were pre-eminently the scientific members of the community and were possibly sometimes credited with even more profound knowledge than they possessed. They constituted the only scientific profession, the clergy, as a rule, being eminently unscientific, and the bar being opposed to any science which might for the moment be hostile to the interests of a client. Within the memories of men of scarcely more than middle age, the applications of chemistry to agriculture and to manufactures, and the applications of electricity to telegraphy, to lighting, and to locomotion, have called into existence large classes of non-medical persons who are accomplished in these branches of science, and among whom the speech of a smatterer would betray him. The medical profession could fall into no more fatal error than to neglect the change in its relative position which the upspringing of these new professions has brought about, unless it were that of remaining content with a slight and superficial knowledge of matters bearing upon their proper pursuits, and concerning which many of their patients would be competently instructed. In so far as the art of healing rests upon the judicious application of physical science to the conditions of the sick, or in so far as the doctrines of physiology rest upon the control of vital operations by physical forces, the medical practitioner, if he is to hold his own among the members of the many new scientific callings which have sprung into existence around him, must have sufficient knowledge to be able to discuss physical questions in the light of the latest discoveries and to display a clear comprehension of physical phenomena. If he be called upon to speak of the chemistry of digestion in the house of a chemist, or of electrical treatment in the house of an electrician, it is necessary for him to be sufficiently at home in either subject to be able to command the confidence of the skilled persons among whom he is thrown. Superficiality of acquaintance with the matter in hand would not only be detected, but would be likely to lead to distrust of his capacity in matters beyond their ken. The "WILLUM" of our anecdote is, after all, a type of human nature, and most people are prone to gauge the capacities of others by the measure of their own. A competent electrician, for example, would regard a medical man who prescribed or discussed electrical treatment, and who at the same time manifested imperfect acquaintance with the principles of the science, very much as he would regard an artisan who was capable of hanging an electric bell by rule of thumb but who could not safely be relied upon for any work in which a knowledge of principles was required. He would be likely also to measure the quality of his medical and surgical knowledge by the standard of his electrical knowledge, and to extend to him for the future a very modified form of confidence. On such grounds as these, and even apart from the important practical bearings of the physical sciences upon the prevention and cure of disease, we would urge upon licensing bodies the pre-eminent necessity of so conducting medical education that the practitioners of the future may be adjusted to what is practically a new environment of learning and may be able to sustain the banner of their calling amid the press. A reputation for contentment with a smattering of science would be fatal to the status of the medical profession, and no regard to the apparent temporary interests of a corporation should be permitted to lead up to such a catastrophe.

The Revision of the British Pharmacopœia.

IT is now more than five years since the present Pharmacopœia was issued, and the time seems fully ripe for taking cognisance of the various criticisms that have been made and of the numerous researches which have been conducted to test the accuracy of the various statements therein or to suggest improved methods. Notices of these criticisms and researches have hitherto appeared in various contemporaries but they have necessarily been somewhat scattered and were not therefore readily accessible. Many researches have been made at the instigation of the Pharmacopœia Committee by workers selected on account of their special acquaintance with the subjects upon which information was desired; other large groups of researches have been conducted in the research laboratory of the Pharmaceutical Society at the suggestion of a joint conference of representatives of the Pharmacopœia Committee of the General Medical Council and representatives of the Pharmaceutical Societies of Great Britain and Ireland; other researches have been made by numerous persons interested in chemistry and pharmacy. Many valuable reports have therefore been in the hands of the Pharmacopœia Committee, ready for consideration or adoption when the task of revision was commenced, but others which appeared in the columns of various journals were in danger of being overlooked unless some serious effort was made to focus all information relating to the Pharmacopœia in some convenient form. Realising this danger, and also the importance of intrusting the compilation to an independent chemist or pharmacist, the Pharmacopœia Committee of the General Medical Council instructed Mr. WILLIAM CHATTAWAY of the Society of Apothecaries to collect and to abstract those published criticisms, researches, and suggestions which he deemed worthy of serious consideration. This Digest has now been published, and will probably facilitate not only the labours of the Pharmacopœia Committee but also those of all who are interested in the progress of pharmacy, since in the brief space of 72 pages we find summarised all really important suggestions, while in each case careful reference to the source of the original papers is given. An alphabetical arrangement has been adopted in harmony with that in the British Pharmacopœia; hence anyone conducting original researches can ascertain at a glance what progress has already been made or what modifications of official statements have hitherto been suggested.

Many criticisms which appeared very shortly after the appearance of the Pharmacopœia were inevitably based upon a conservative spirit which resented innovations; some, indeed, betrayed indications of hasty judgment or even of rapid and faulty observation, and these were dealt with in a report by Professor JOHN ATTFIELD who had edited the Pharmacopœia and who noted and rectified any minor misprints or errors to which attention had been directed. The greater part of the serious investigations dates from the beginning of the year 1899 and this has therefore been selected as the earlier limit of the Digest. Mr. CHATTAWAY, in his preface, states that the criticisms bear mainly upon the composition and assay of drugs and galenicals, while the criticisms dealing with the botanical features of drugs are remarkably few. Both these things were to be anticipated, since the responsibility for the accuracy of botanical features in the Pharmacopœia was intrusted to Sir W. T. THISELTON-DYER, director of the Royal Botanical Gardens, Kew, and to Mr. E. M. HOLMES, curator of the Pharmaceutical Society of Great Britain. On the other hand, although the composition and assay of drugs were largely the result of suggestions from a committee appointed by the Pharmaceutical Society of Great Britain, and therefore presumably represented accurately the state of knowledge in 1898, these subjects are more continuously liable to modifications, due to improvements in pharmaceutical processes and the minute daily researches to which they are submitted. It is evident from consideration of the Digest that it contains much information in a form immediately available for inclusion whenever the revision of the Pharmacopœia is undertaken, but it is also clear that some of the criticisms and suggestions will need verification and that certain new investigations must be initiated before the present authoritative statements can be set aside or amended. Inasmuch as the majority of the criticisms are evidently the result of private enterprise, it may be hoped that the publication of this digest will further stimulate private research towards their confirmation or refutation. The progress of pharmacy has everything to gain from such private work when conducted with obvious care and attention to detail, and it is probable that the researches will be best conducted by those who feel personal interest sufficient to prompt them to select their own subjects of investigation. Some few criticisms, however, must necessitate research in well-appointed laboratories fully equipped with apparatus and with assistants who can devote their whole time and energy to the work, and since a large part of the expense of these must fall upon the General Medical Council it is to be feared that, unless great care is exercised, they may be so costly as ultimately to involve an increase in the price of the Pharmacopœia. Happily the need of such expensive researches does not seem to be very great to judge from the digest at present before us; minor errors can be readily amended, matters of opinion can be referred to competent authorities, and numerous suggestions apply to drugs or galenicals which, it is to be hoped, will be excluded from the next Pharmacopœia.

While Mr. CHATTAWAY is to be congratulated upon the restraint and brevity with which he has accomplished the arduous task of collating and compressing into such small space so much valuable information, further congratulations are due to those responsible for the British Pharmacopœia upon the labour which must have been expended in producing a volume which, published "by authority," has so successfully withstood the numerous assaults provoked by all authoritative statements.

Longevity.

To be truly interesting a lecturer should always draw largely from observation. That he should be well-equipped in the literature of his subject is an essential but unless the facts previously recorded are to fall flat when again passed through the revivifying process of redelivery they must be illumined with apt illustrations drawn from the speaker's experience, and the interest is intensified when this experience is personal instead of being derived from observation of others. For these reasons Sir HERMANN WEBER'S lecture recently delivered before the Royal College of Physicians of London on Means for the Prolongation of Life merits special attention, although, as was to be expected, it disclosed no new royal road which would infallibly solve all difficulties. Quite early in the lecture Sir HERMANN WEBER instanced his own case as an example of the defeat of hereditary tendencies and it is therefore legitimate to remind our readers that he obtained his medical degree so far back as 1848. Sir HERMANN WEBER'S parents both died before they attained the age of 60 years, so that he spoke at any rate as one who had discounted any influences of heredity towards short life. These personal details are mentioned for the consolation of those who might be depressed by his remarks on the advantage of belonging to a long-lived family and the power of influencing heredity. Well-selected marriages, from which so much has been hoped by certain writers, must always fail to be consolatory to the individual who has to take his parents as he finds them, while a parent must be sanguine if he hopes to influence the marriages of his offspring by prudential considerations. Still, the tendency to vascular degenerations and to surrender to the invasion of certain bacilli must be regarded as hereditary, and there was some solace in finding that in the lecturer's experience such dangers may be evaded by personal care.

It is to the rising generation that Sir HERMANN WEBER'S cheery optimism will mainly be welcome since he laid so much stress upon the importance of exercise, of the week-end holiday, and of the summer holiday, a point of view which he shares with all healthy minded students. The chief exercise extolled was that of walking, and he advocated this in all weathers; but almost equal importance was attached to artificial respiratory exercises; and although as years advance these may be carried out with due solemnity in accordance with instructions given at some length, youth will hinder their earlier adoption so long as natural respiratory exercises can be obtained in football and in cricket. The question of the amount of food which may judiciously be taken was one upon which many quotations were made all tending in the general direction of moderation, the avoidance of excess, and the reduction of meat and flesh food. Similar restrictions were placed upon alcohol, "the most frequent cause of crimes and of the ruin of many families," though a quotation admitted that a "few hard drinkers were amongst the long-lived." Tea, coffee, and cocoa were upon the whole kindly treated, their power of disturbing digestion under some conditions was recognised, while their benefits were extolled. Similarly with regard to tobacco, very little guidance was afforded and no hard-and-fast line was drawn. Tobacco was said to be a means of enjoyment, to soothe nervous irritability, to make men look more contentedly on their troubles, and in excess to produce bad effects. This we hold to be common experience, although so judicial an attitude may have been unacceptable to many who anticipated that tobacco might be condemned. The avoidance of constipation by modifications of diet occupied a great deal of attention and the comparatively simple measures by which discomforts might frequently be minimised without resorting to drugs formed also an important part of the address. The most interesting part of the lecture was, however, that devoted to the nervous system in its influence upon the body generally. Sir HERMANN WEBER said that degeneration of the vessels of the brain, in spite of hereditary tendencies, can be retarded or even avoided by judiciously arranged mental work and occupation, in conjunction with great moderation in food and stimulants and with regular physical exercise. He supported his contention by several instances from his own experience and encouraged the cultivation of cheerfulness and a happy and placid mind. The amount of sleep he allowed would scarcely satisfy the instinctive craving, and still less in accord with custom was his recommendation to get up at the same hour daily, even after exceptionally late hours of work or a poor night's rest. Here we believe his advice to be sound generally; but idiosyncracy plays a great part in the hours of rest required by an individual, and we are certain that his dictum could not always be followed with advantage.

While expressing concurrence with the principles laid down by Sir HERMANN WEBER there are still a few uneasy questions left unsolved. He assumed that the prolongation of life is to be desired and he emphatically expressed his conviction that it is a mistake to consider that ordinary work wears out the organs sooner than idleness or great restriction in work. He supported his contention by numerous examples of hard workers who have retained unimpaired intellectual faculties to very advanced ages. He even quoted CICERO who held that "the intellectual powers remain in the old provided study and application are kept up, and old age need not be inactive, indolent, and drowsy." Still, we venture to question whether the majority who have witnessed many death-bed scenes so often preceded by painful circumstances really desire to live to a great age. If afforded the power to choose would not many prefer, to instance examples from the lecture, to die near the age of 60 years from apoplexy rather than to live on to 70 or more to struggle with heart disease and pneumonia? The former mode of death is less painful, more merciful. We have to deal with generalisations rather than with exceptional instances and unhappily at present there is still a lurking feeling that the last scene of all is usually

> "Second childishness and mere oblivion;
> Sans teeth, sans eyes, sans taste, sans—everything."

Sir HERMANN WEBER thinks it need not be anything of the sort and his rules of life forcibly recall those long since playfully-formulated in "Alice in Wonderland." Exercise of the brain and of the limbs and due development of the muscular strength of the jaws formed the main secrets of longevity imparted by the evergreen sage to the inquisitive youth in LEWIS CARROLL'S delightful rhyme. Sir HERMANN WEBER has added to the old man's list in serious scientific terms but his conclusions might almost be summarised in three words—moderation, cheerfulness, and exercise.

Annotations.

"Ne quid nimis."

A STANDARD FOR LEAD GLAZES.

MORE than two years ago Lord James of Hereford was appointed arbiter to decide between the views of the Home Office in regard to protecting the lives and health of the workpeople in the pottery trade and the representations of the manufacturers. The proceedings were brought to a somewhat sudden termination in November, 1901, by Lord James declaring that as it was shown that lead poisoning had greatly decreased under the last rules of the Home Office there was no need to impose fresh ones, at all events for the moment, as to the use of "fritted" lead or as to the examination of adults. These questions he considered might be postponed for 18 months and would be then again postponed if necessary. While we were aware that any determination then and there to enforce the use of standard lead "fritts" would have been a source of temporary inconvenience to the industry, yet we expressed the opinion that in the face of the conclusions to which the Government experts, Dr. T. Oliver and Dr. T. E. Thorpe, had come, the adoption of definitely "fritted" lead should not be delayed and that no time should be lost in affording protection to those engaged in pottery manufacture. We now learn that Lord James has recently signed his final award in which a standard for "fritts" is definitely laid down. It is generally provided in a new rule (2) in this award that after Feb. 1st, 1904, no glaze shall be used which yields to a dilute solution of hydrochloric acid more than 5 per cent. of its dry weight of a soluble lead compound calculated as lead monoxide when determined in the manner prescribed by the rule. In the original standard of insolubility proposed by Dr. Thorpe and Dr. Oliver, a maximum of 2 per cent. of soluble lead was suggested as a criterion of safety upon which glazes might be judged. The use of a glaze, however, which does not conform to a 5 per cent limit is to be permitted after due notice has been given to the inspector of the district. This permission, be it remarked, is subject to the adoption by the manufacturer of a new schedule of compensation to employés who may be suspended on being certified as suffering from lead poisoning, and subject also to periodic examination of the employés by the certifying surgeon. China scouring is excluded from the processes dealt with by these regulations. Lord James, we think, has been very painstaking and impartial in dealing with this matter, for at the outset while he made up his mind not to interfere hastily with trade considerations yet he felt that his prime concern related to the particular questions of life and health involved in the inquiry. Certainly the manufacturers have had ample warning that legislation would sooner or later be directed towards enforcing the use of a lead compound of a definitely modified character, that in other words there would be a limit placed upon its solubility, and the limit suggested—namely, 5 per cent.—is a compromise between the views of the Home Office experts and those of the masters in the trade. The prescribed method of testing the solubility of the glaze is quite simple and such as can be easily conducted by any person possessing an average amount of intelligence. It is enjoined that "a weighed quantity of dried material is to be continuously shaken for one hour at the common temperature with a thousand times its weight of an aqueous solution of hydrochloric acid containing 0.25 per cent. of pure acid. This solution is thereafter to be allowed to stand for one hour and to be passed through a filter. The lead salt contained in an aliquot portion of the clear filtrate is then to be precipitated as lead sulphide and weighed as lead sulphate." This method is practically in a line with that adopted by some of the expert members of a committee appointed to inquire into the subject on behalf of the Home Office several years ago.

THE REBUILDING OF ST. BARTHOLOMEW'S HOSPITAL.

IN our issue of Dec. 5th we wrote in a leading article to the effect that it is absolutely necessary that the scheme for the rebuilding of St. Bartholomew's Hospital should be one which might be final. We pointed out that it was certain that the ordinary citizen would not subscribe to a scheme which was imperfect. In confirmation of our opinion there appeared in the *Times* of Dec. 7th a letter dated Dec. 1st from Mr. Andrew Motion, a life governor of the hospital and the chairman of the Cannon Brewery. In it he says: "My pen and my purse will be used to frustrate St. Bartholomew's Hospital being ruined for all time. Should it, on the other hand, be decided to rebuild on Sir H. Burdett's plan or a similar one my firm will subscribe £5000, but if the patchwork and tinkered scheme be adopted not a sixpence." This sentence shows the opinion of one large business firm and we are certain that the other large firms in the City will take the same view. We may say here that we have received a letter from Messrs. Hubbard and Moore, architects, of Gresham-street, pointing out that according to modern views no hospital should have more than 50 beds per acre and they estimate that on this scale 700 beds would require 13½ acres and would cost in all £1,612,000, a sum which would be financial ruin. They therefore propose that the hospital should be rebuilt in two portions, one on the present site and the other in the country, the lately acquired one and a half acres being sold to provide land and buildings for the latter. We cannot agree with this suggestion. Our own advice is once again to appeal to the Lord Mayor and to the governors of St. Bartholomew's Hospital to lay before the citizens at the forthcoming meeting on Jan. 26th, 1904, a large and generous scheme. Let the citizens at least be asked to procure a sum of from £800,000 to £1,000,000, and let the Lord Mayor assure the meeting that if the money be raised additional land will be bought and St. Bartholomew's Hospital rebuilt in a manner consonant with its traditions and with the history and traditions of the heart of the empire, and we cannot but think that the sum will be forthcoming.

THE VALUE OF SYMPTOMS IN DIAGNOSIS.

Dr. J. Rose Bradford, in delivering the Purvis oration before the West Kent Medico-Chirurgical Society at the Royal Kent Dispensary, Greenwich, on Dec. 4th, took as his subject the Value of Symptoms in Diagnosis. After discussing the importance of the diagnosis of disease, Dr. Bradford went on to point out that it was essential in the treatment and in the prevention of disease for the malady to be recognised in its early stages and in what might be called its mild varieties. The accurate diagnosis of disease was essential for another reason—namely, it not uncommonly happened that under a given clinical description there were included a variety of separate pathological processes, and Dr. Bradford quoted ulcerative endocarditis as an example. The great majority of the many difficulties and uncertainties in the practice of medicine arose from imperfect or inaccurate diagnosis which very often depended on the present imperfect state of the knowledge of medicine but in some instances on a want of appreciation of the symptoms presented by disease. Many practitioners had become so impressed with the value of physical signs that it was not uncommon for a diagnosis to be made entirely from physical signs, the symptoms being almost neglected. Physical signs, as a rule, only gave information as regarded the anatomical seat of the lesion—they did not give necessarily information concerning its pathological nature, and many errors of diagnosis in disease arose from confusing those two distinct phenomena. The importance of the thorough study of symptoms must be at once granted when it was remembered that in a large number of functional diseases symptoms only were present. In many functional diseases the remarkable character of the subjective sensations complained of by the patient afforded a clue to the differentiation of the malady from organic diseases with which at first sight it might be confounded. One of the most important functional diseases of the nervous system in which the diagnosis had to be made in most cases entirely on the symptoms was epilepsy and more especially the anomalous form of epilepsy in which convulsions were absent, particularly *petit mal* Continuing, Dr. Bradford pointed out that some of the most serious gross organic diseases might reach a very high stage of development and yet produce few, if any, physical signs. These diseases might be revealed only by the occurrence of symptoms which in some of the more fatal of them might be misinterpreted. The lecturer quoted hepatic cirrhosis as an example and observed that that disease might proceed to a very high degree of development and yet symptoms only might be present and these might not uncommonly be found to be referred to the stomach rather than to the liver. Further instances of maladies in the same category were gastric ulcer, affections of the cerebral arteries, and Addison's disease. Proceeding to the next class of disease illustrating his contention, Dr. Bradford quoted renal and biliary colic as affording good instances of organic diseases in which symptoms only might be present and where the differential diagnosis had often to be made almost entirely on the symptoms. The next point commented on by the lecturer was that of the onset of complications and in this connexion he observed that one of the most important subjects concerned with the study of symptoms was the information which they afforded of the onset of complications in gross organic disease. In many instances, doubtless, those complications were necessarily fatal but in others the only chance of saving a patient depended on the prompt recognition of the nature and cause of those symptoms. He gave as familiar illustrations of his contention the occurrence of perforation in enteric fever and in appendicitis where, if treatment were delayed until all the characteristic signs of the presence of gas in large amount in the peritoneum were present, the chances of successful interference would be very greatly diminished. Passing on to the discussion of symptoms as a clue to diagnosis of the nature of a lesion, Dr. Bradford gave the common occurrence of vomiting in cases of cerebral hæmorrhage as an illustration. The sudden onset of hemiplegia almost always raised the question as to whether a lesion was thrombotic, embolic, or due to hæmorrhage, and in a great many cases the history of the first symptoms, and especially, perhaps, the occurrence of vomiting, afforded conclusive evidence of the presence of cerebral hæmorrhage. Another symptom often throwing unexpected light on the diagnosis of disease was the numbness and tingling of the extremities so characteristic of neuritis and occurring as a very early symptom in that disorder. Dr. Bradford then entered in detail into the value of pain as a symptom and, after commenting on the significance of delirium, mentioned how dyspnœa in its varied forms was often of great assistance in arriving at a correct judgment. Dr. Bradford concluded an interesting oration by describing how the occurrence of symptoms might afford valuable indications for treatment, at the same time being in some cases the only means of making the diagnosis. So whether medicine was regarded from the point of view of diagnosis, prognosis, or treatment it was most important in all cases to pay great attention to the study of symptoms if success was to be achieved.

NATIONAL PHYSIQUE AND THE EDUCATIONAL AUTHORITIES.

WE commend the attention of our readers to the thoughtful article which appears under this title in the current number of the *Guardian* from the pen of the Right Hon Sir John Gorst. It will be remembered that Sir William Taylor, the Director General of the Army Medical Service, having presented a memorandum to Parliament calling attention to the deterioration in the health and physique of the men offering themselves as recruits for the army, a committee was appointed to advise the Government as to the propriety of appointing a Royal Commission to investigate the physical condition of the British population. Sir John Gorst points out that much information could be obtained from one source without awaiting the lengthened deliberations of a Royal Commission. Four-fifths of the child population of Great Britain come under the daily observation of public authorities and concerning these children the following two questions can be asked and answered: (1) What is their physical condition ? and (2) What can be done by public authority to improve it? The Board of Education, the local education authorities, and the teachers could give, Sir John Gorst thinks, a complete answer to the first and a practical if incomplete answer to the second question. There is no reason, says Sir John Gorst, why it should not be the duty of every class-teacher to make a daily inspection of the children in the class and to record and to report anything abnormal, such as hunger, nakedness, dirt, and disease. This daily inspection could be *periodically supplemented and checked by the visit of a* trained nurse and by such means it is suggested that we should soon learn whether we were degenerating or improving. With much of Sir John Gorst's words we fully agree, but we question whether the teacher is, as a rule, capable of giving the systematic help that is thus expected of him. He could report about clothing and to a great extent about personal hygiene; he could inquire about feeding; but disease would be beyond him save in its grosser manifestations. Medical examination of all school children upon some pre arranged plan would be necessary before the information to be *obtained from school authorities could be relied upon.* If all teachers of the young were themselves instructed in physiology the position would be different. An address delivered at the University of St. Andrews by Dr. D. Fraser Harris at the beginning of the week and referred to briefly by one of our Scotch correspondents urged the necessity of the schoolmaster being familiar with at least the groundwork of physiology and Sir John Gorst's excellent paper teaches a similar lesson.

CHRISTMAS ENTERTAINMENTS AND THEIR DANGERS: A WARNING.

FAR be it *from us to detract in the smallest degree from the joys and amusements which are commonly indulged in* at Christmas time for the sake chiefly of the little people. But previous experience has taught us unhappily that Christmas time is prone to bring a sad chapter of accidents (much sadder than usual because of their occurrence at a peculiarly joyous time) which with a little forethought might have been avoided. Perhaps it is in connexion with domestic theatricals that the worst accidents have arisen. Children and adults alike have been dressed up, for example, and almost buried in a profusion of cotton-wool intended to represent snow without the least regard having been paid *to the ready inflammability of the material and* without any precautions to keep it from coming into contact with a naked flame. Some most heart-rending scenes have resulted from this want of care and a very sad sequel to happy moments has been the consequence. It cannot be too well known that cotton-wool burns with the fierceness of spirit and that the flame is very hot and very difficult to extinguish. Great caution should also be exercised in regard to the drapery used for scenic purposes which *should* consist *so far as possible, if not entirely,* of non-inflammable or of not easily ignited material. There is again a similar danger connected with celluloid ornaments and toys. The celluloid ball is fiercely and easily inflammable and if it does not ignite something else and lead to an alarming conflagration it may itself inflict severe burns and injury. This warning is all the more needed, it seems to us, as so many toys are now made of this highly combustible material. The festive season is associated with *many things bright and pretty in which* danger may easily lurk. The painted doll may be pigmented with poison, the coloured candles on the Christmas tree have been known to be a source of arsenical poisoning at Christmas parties, while the sweets may not be above suspicion. We cheerfully admit, however, that there never was a time when colouring materials were as a rule so innocent in character as at the present, thanks maybe to the publicity given in our own columns *to the practice at one time in evidence of using* poisonous materials for this purpose. If to be forewarned is to be forearmed this little note may not be written in vain. We feel strongly that a warning of this kind is timely and we issue it not with the slightest desire to cast a wet blanket over a promised joyous time but in the sincere hope that this Christmas may not be marred by those sad occurrences which have occasionally marked previous festivals and which could have been avoided by taking care and by the application of ordinary intelligence as to the possibilities of danger.

THE BALLACHULISH QUARRIES.

FURTHER proof reaches us during the week that the Ballachulish quarriers are determined not to yield on the question of their medical officer, and it seems clear that the mass of them, unless the directors of the company revise their opinion, will seek permanent employment elsewhere. The persecution, for it is nothing else of Dr. Lachlan Grant will not be endorsed by the men whom he has served well and whom he is desirous of serving further, nor are the men prepared to accept *dictation as to what medical man they* shall employ while the payment of the medical man is made by themselves.

5000 MIDWIFERY CASES IN GENERAL PRACTICE.

A NOTE on 5000 midwifery cases in private practice has reached us from a contributor who desires to affix only the initials "G. P." to his work. The note commences with an analysis of the cases as follows: cases attended, 5000; twins, 50, or 1 per cent.; triplets, 2, or 0 04 per cent; transverse presentations, 74, or 1·48 per cent.; face presentations, 7, or 0·14 per cent.; placenta prævia, 17, or *0 34 per cent.; puerperal eclampsia, 6, or 0 12 per cent.;* puerperal mania, 2, or 0 04 per cent; ruptured uterus, 2, or 0 04 per cent; version, 66, or 1·32 per cent.; forceps, 326, or 6 52 per cent.; craniotomy, 1, or 0·02 per cent.; 306, or 6·12 per cent, paid no fees. Deaths occurred as follows: acute septicæmia, 2, or 0 04 per cent.; influenza (?), 2, or 0·04 per cent.; pyæmia, 1, or 0·02 per cent.; shock after craniotomy, 1, or 0·02 per cent.; ruptured uterus, 2, or 0·04 per cent.; puerperal eclampsia, 3, or *0·06 per cent.; post-partum* hæmorrhage, 1, or 0 02 per cent.; total, 12, or 0·24 per cent. Other deaths not directly due to parturition: acute bronchitis, 2, or 0·04 per cent.; phthisis, 2, or 0 04 per cent.; cerebral hæmorrhage, 1, or 0·02 per cent.; puerperal mania and phthisis, 1, or 0·02 per cent.; total, 6, or 0·12 per cent; total number of deaths, 18, or 0·36 per cent. All these cases were attended in the East-end of London and *do not include* those in which help was given to other practitioners or midwives. The number of cases of placenta prævia is small. In cases where the fœtus was not viable they would have been looked upon as miscarriages. Abortions and miscarriages in the East-end of London are too numerous to mention. The two deaths attributed to influenza occurred as follows. Both were attended by A one afternoon. In the evening he was prostrate with a sharp attack of influenza. *Both cases ran a similar course.* On the second day the patients were feverish, with pains in the back and the limbs; no rigors were present. On the third day the temperature rose to 104° F. and there were abdominal tenderness and sleeplessness. There was no milk and the lochia were scanty. The symptoms continued till the seventh day but the temperature dropped. One case was then seen by a specialist *in gynæcology, who found* no uterine, pulmonary, or cardiac physical signs. The diagnosis was influenza and the prognosis was favourable. That evening vomiting and delirium came on and continued till the eighth day, when death occurred. In the three deaths from eclampsia convulsions took place in one case three hours post partum, in the second 11 hours post partum, and in the third before the os had begun to dilate. The patient who died from post-partum hæmorrhage was delivered by forceps at 8 P.M. She had had difficult labours previously and had always lost blood considerably. At 6 A.M. her friends sent to say that she was dead. There had been a good deal of hæmorrhage externally and the uterus was distended with blood. In the following series of monsters in each case the husband and wife were cousins: (1) miscarriage; (2) anencephalous monster; (3) living, normal; (4) hernia cerebri, five fingers and six toes on each hand and foot, double talipes varus, cleft lip and palate; (5) normal, living; (6) normal, living; (7) anencephalous monster; (8) has left the district and is said to have had "another monster." Besides the 306 who did not pay anything a large number paid only a part of their fees. When "twelve good men and true" are so ready to censure a practitioner who demands his fee before turning out from his bed they should bear this in mind. Seeing the conditions under which many of these cases are attended—the rooms, the bed, the skirt, worn during labour, which has swept the streets for months—the practitioner can only be thankful that there is such a thing as the vis medicatrix naturæ.

NURSING STAFF TROUBLES.

THERE are few positions in which correct, judicious, and considerate conduct is more difficult of attainment than it is in the case of the matron of a large hospital. The position of an autocrat is a difficult one, even when he is a man among men; when the autocrat is a woman among women great indeed are the merits of her who pleases both those whom and those for whom she rules. Governing bodies generally and wisely interfere but little in the direct control of the nurses by the matron. Very great, therefore, is the credit due to the ladies whose rule in these difficult positions seldom gives rise to complaint, to friction, or to insubordination. Many of our readers no doubt are aware that there has lately been some difficulty in connexion with the nursing staff at Charing Cross Hospital. If we may trust the account given in the general press the matron, as representing and as acting for the supreme authority in the institution, seems to have behaved with perfect openness and justice. In her opinion the retirement of certain sisters was advisable. The hospital authorities gave these ladies the opportunity of retiring in a convenient and graceful manner. Here, it seems to us, the matter should end.

QUARANTINE WORK IN THE PHILIPPINE ISLANDS.

THE annual report for the period ended July 31st last, of Captain V. G. Heiser, United States Public Health and Marine Hospital Service, chief quarantine officer of the Philippine islands, has just been made public. From a perusal of the summary of a year's quarantine work in the Philippine Archipelago it is gathered that there are now on duty in the Philippines four commissioned officers at Manila and Mariveles, one each at Cebu, Iloilo, and Jolo, one pharmacist at Manila, and 70 attendants who act in the capacity of clerks, launch crews, quarantine employés, and so on. 207 vessels were fumigated with sulphur. 105 vessels infected with cholera were disinfected. Seven vessels with small-pox aboard and two with plague cases were disinfected. In addition there were 119 vessels disinfected because they came from infected ports. The report states that with the possible exception of Tor, Egypt, there is probably more disinfection accomplished at the Mariveles quarantine station than at any other plant in the world. Cholera was the disease with which the quarantine officers in the Philippines had chiefly to deal. 68 vessels with cholera on board arrived at the port of Manila and on 37 vessels cholera appeared during the time they were serving their outgoing quarantine. Captain Heiser is a strong advocate of strict quarantine regulations and says: "It is a matter for congratulation that the practice prescribed by the quarantine laws and regulations has been so thoroughly vindicated by practical experience. Of the 105 cholera-infected vessels that were disinfected at the Manila station only one developed the disease after being released from quarantine and then nine days after disinfection." With regard to the plague the report states that it is particularly creditable to the officers on duty in China and Japan that notwithstanding the fact that plague has been epidemic at Hong-Kong and Amoy during the year and present at other ports in those countries not a single case of this disease found in Manila could be traced to infection from without. The destruction of rats, other vermin, and cockroaches on board vessels at ports in the Philippine islands has been carried on with energy and much success during the period covered by the report. A few cases of leprosy were detected on vessels visiting Manila during the year. According to the report, the endeavour to prevent the occurrence of quarantinable diseases in the Philippine islands after those now present have been stamped out will require the strict observance of the quarantine laws and regulations at the ports of entry. As some of these ports are less than 48 hours by steamer from countries in which diseases like cholera are endemic the problem will be a difficult one and perhaps more than can be expected of the quarantine service alone, but it is hoped that with the assistance of an intelligent, energetic Board of Health it will not be impossible.

THE AFTERMATH OF BAYLISS *v.* COLERIDGE.

WE deal in another column with the purely legal aspects of the libel case of Bayliss *v.* Coleridge which was recently decided in the law courts. We had hoped that with the finding of the jury the matter would have been allowed to drop. But events have happened and are happening which tend to prolong a useless controversy and which do not show the morality of an antivivisection society in a very favourable light. Mr. Coleridge was compelled by the verdict of the jury to pay a sum of £2000 damages and also to pay the costs. He thereupon, according to a statement made by his solicitor which appeared in the *Times* of Dec. 2nd, paid over from his private account a cheque for £2000, which cheque was duly sent to the plaintiff's solicitors on Nov. 19th. A paragraph afterwards appeared in the *Manchester Daily Dispatch* to the effect that the National Antivivisection Society had paid Mr. Coleridge's damages and costs. This was the statement which Mr. Coleridge's solicitor wrote to contradict. He added: "Mr. Coleridge also requests me to state that he has no intention of asking the society to contribute in any way to the payment of the damages or any of the legal expenses." As was to be expected, the London correspondent of the *Manchester Daily Dispatch* was not going to allow this traversing of his statement to pass unnoticed and accordingly in the *Times* of Dec. 7th appeared a letter from him inclosing for the information of the editor of the *Times* a circular sent out from the National Antivivisection Society under date Dec. 1st appealing for subscriptions to defray Mr. Coleridge's expenses and damages. The society also wrote on Dec. 2nd to the correspondent of the *Manchester Daily Dispatch* asking him to contradict a statement in which there was no word of truth and stating, moreover, that not only had the society not paid the costs and damages but that it had no intention of doing so. Mr. Coleridge may not have asked his society to pay his damages and costs but it is quite evident either that the society is as a whole ignorant of what its presidents and vice presidents, together with its chairman of committee, are about or that it is telling untruths A circular is issued by the society dated Dec 1st appealing for subscriptions to *defray Mr Coleridge's very heavy expenses*, while on Dec. 2nd the same society writes a letter *to say that it has* neither paid the expenses nor is it going to do so In one point the London correspondent of the *Manchester Daily Dispatch* is in error—namely, where he says that the society had paid the expenses It has not yet, but by its own circular it is asking for money to do so If this is not intention, what is it? Mr Coleridge's solicitor, writing in the *Times* of Dec 8th, argues that the National Antivivisection Society is not going to pay but that it is merely asking its subscribers to contribute *money for such* a purpose The difference between a society and the members of a society seems to us so small as to be negligible and the argument employed—namely, that the *members of* the society are being asked to pay but that the society itself is not going to pay—is a piece of casuistry

ENTERIC FEVER SPREAD BY WATER-CRESS

DURING the month of June there was noticed to be an unusual increase in the number of cases of enteric fever reported in the metropolitan borough of Hackney Dr J King Warry, the medical officer of health of the borough who has recently sent in his report of the outbreak to the public health committee of Hackney was so struck by this incidence that he was led to suspect that some special agent was responsible His report, which lies before us, reminds those to whom it is addressed that June is as a rule the month in which enteric fever is at its lowest point and the seasonal prevalence of the disease does not generally set in until August But on June 6th two cases were reported, on June 13th six cases were reported, on June 20th 14 cases were reported, and on June 27th there were eight cases Thenceforward the number of cases reported weekly remained at a number below eight until August 1st when they rose to 11 In the following week there was a drop but during the three following weeks the numbers were 15, 16 and 16 respectively There were thus two waves of disease the first covering a period of eight weeks from the second week of June to the week ending July 25th and including 48 cases almost all located within an area represented by a circle of one third of a mile in radius, the centre being situated in the Clarence road Wave No 2 included 62 cases notified within nine weeks, mostly located within a circle of half a mile radius, the centre of which was situated near Orchard street Dr Warry investigated all the usual sources of the infection of enteric fever, such as water, milk ice creams, and shell fish, and could not satisfy himself that any one was in fault He was struck, however with the fact that of the cases forming wave No 1 no less than 64 4 per cent had partaken of water cress during the three weeks prior to the origin of the illness Of the second set of cases 55 3 per cent had eaten water cress during the same period Dr Warry therefore caused 17 samples of water cress taken from places where the patients marketed to be examined and six of these samples came from the beds at West Ham All the samples showed sewage organisms and a sample of water from the West Ham beds contained at least 50 bacilli coli communes in every cubic centimetre It therefore appeared evident that the cause of the outbreak was the consumption of water cress grown in beds fed with sewage Dr Warry suggests that as a result of his inquiry "(1) an extended inquiry should be made as to the conditions under which water cress supplied to the metropolis is cultivated, (2) representations should be made by the borough council to the county borough of West Ham, pointing out the conditions under which water cress is cultivated in that borough, and asking them to take such steps as may be needful to ensure in future that water cress grown in that borough shall be free from pollution" Water cress when *clean is an excellent* and wholesome vegetable food and every effort should be made by the health authorities of London to see that it is supplied free from sewage contamination

THE MEDICAL GRADUATES' COLLEGE AND POLYCLINIC

MR JAMES CANTLIE presided at the fifth annual dinner of the members and friends of the Medical Graduates' College and Polyclinic held on Dec 3rd at the Trocadéro Restaurant, Piccadilly circus, London, and in the course of proposing the toast of "The Polyclinic" said that the primary object of the institution was to better the equipment of the medical practitioner in battling with disease and in that way the Polyclinic deserved the support of the public in working for the health of the community He reminded his hearers that medical men from all parts of the world had availed themselves of the benefits to be derived from the teaching at the college and they had attended in numbers beyond the anticipation of the most optimistic The number of attendances of medical practitioners since 1900 had steadily increased and in 1903 they were well over 15 000 He did not pretend that post graduate teaching had its commencement in the foundation of the Polyclinic but he asserted that never before in any institution in this or in any other country had such a plurality of distinguished teachers been collected together in one building The teachers at the Polyclinic were drawn from Dingwall to Portsmouth, from Ireland and from Wales from Canada from Australia, from the United States and from the length and the breadth of the continent of Europe *For those reasons he claimed* that the institution was a true Polyclinic He contended that it was impossible for any single medical school to carry on *satisfactorily true post graduate teaching, for* the education at the medical schools was not final Men learnt at those centres the means of commencing the medical profession but in the Polyclinic they had something which stood to the medical schools in the same relation as the universities stood to the public schools It had to be remembered that in medicine progress proceeded apace and the truths of their youthful days were in many cases no longer above criticism In commenting on the considerable opposition that had been offered to the Polyclinic Mr Cantlie observed that it was not to be wondered at because no great idea had ever been introduced without exciting antagonism Huxley had been preached at from the pulpit obloquy had been thrown on Darwin, Ferrier had to appear in Bow street police court for investigating the functions of the human brain, and even Lister had been met by the opposition of some great surgeons in London who had tried to stem the advancing tide of surgical truths. Mr Cantlie, continuing, said that the initial jealousy against which the Polyclinic had struggled had now passed away and the difficulties in its onward progress had vanished The practice of the Polyclinic in drawing their teachers from so vast a field might well be followed with advantage in some medical schools Men got so bound up in their own schools that they imagined nothing was going on beyond their walls Mr Cantlie said that Mr Watson Cheyne had been telling him of a scheme for a true university by which a man might take out a ticket at the University of London and then go to any medical school he pleased Loyalty to one's own medical school was to be applauded but loyalty to the medical profession was a higher duty which also demanded obedience. Those who came to and in the third before the os had begun to dilate. The patient who died from post-partum hæmorrhage was delivered by forceps at 8 P.M. She had had difficult labours previously and had always lost blood considerably. At 6 A.M. her friends sent to say that she was dead. There had been a good deal of hæmorrhage externally and the uterus was distended with blood. In the following series of monsters in each case the husband and wife were cousins: (1) miscarriage; (2) anencephalous monster; (3) living, normal; (4) hernia cerebri, five fingers and six toes on each hand and foot, double talipes varus, cleft lip and palate; (5) normal, living; (6) normal, living; (7) anencephalous monster; (8) has left the district and is said to have had "another monster." Besides the 306 who did not pay anything a large number paid only a part of their fees. When "twelve good men and true" are so ready to censure a practitioner who demands his fee before turning out from his bed they should bear this in mind. Seeing the conditions under which many of these cases are attended—the rooms, the bed, the skirt, worn during labour, which has swept the streets for months—the practitioner can only be thankful that there is such a thing as the vis medicatrix naturæ.

NURSING STAFF TROUBLES.

QUARANTINE WORK IN THE PHILIPPINE ISLANDS.

THE annual report for the period ended July 31st last, of Captain V. G. Heiser, United States Public Health and Marine Hospital Service, chief quarantine officer of the Philippine islands, has just been made public. From a perusal of the summary of a year's quarantine work in the Philippine Archipelago it is gathered that there are now on duty in the Philippines four commissioned officers at Manila and Mariveles, one each at Cebu, Iloilo, and Jolo, one pharmacist at Manila, and 70 attendants who act in the capacity of clerks, launch crews, quarantine employés, and so on. 207 vessels were fumigated with sulphur. 105 vessels infected with cholera were disinfected. Seven vessels with small-pox aboard and two with plague cases were disinfected. In addition there were 119 vessels disinfected because they came from infected ports. The report states that with the possible exception of Tor, Egypt, there is probably more disinfection accomplished at the Mariveles quarantine station than at any other plant in the world. Cholera was the disease with which the quarantine officers in the Philippines had chiefly to deal. 68 vessels with cholera on board arrived at the port of Manila and on 37 vessels cholera appeared during the time they were serving their outgoing quarantine. Captain Heiser is a strong advocate of strict quarantine regulations and says: "It is a matter for congratulation that the practice prescribed by the quarantine laws and regulations has been so thoroughly vindicated by practical experience. Of the 105 cholera-infected vessels that were disinfected at the Manila station only one developed the disease after being released from quarantine and then nine days after disinfection." With regard to the plague the report states that it is particularly creditable to the officers on duty in China and Japan that notwithstanding the fact that plague has been epidemic at Hong-Kong and Amoy during the year and present at other ports in those countries not a single case of this disease found in Manila could be traced to infection from without. The destruction of rats, other vermin, and cockroaches on board vessels at ports in the Philippine islands has been carried on with energy and much success during the period covered by the report. A few cases of leprosy were detected on vessels visiting Manila during the year. According to the report, the endeavour to prevent the occurrence of quarantinable diseases in the Philippine islands after those now present have been stamped out will require the strict observance of the quarantine laws and regulations at the ports of entry. As some of these ports are less than 48 hours by steamer from countries in which diseases like cholera are endemic the problem will be a difficult one and perhaps more than can be expected of the quarantine service alone, but it is hoped that with the assistance of an intelligent, energetic Board of Health it will not be impossible.

THE AFTERMATH OF BAYLISS *v.* COLERIDGE.

WE deal in another column with the purely legal aspects of the libel case of Bayliss *v.* Coleridge which was recently decided in the law courts. We had hoped that with the finding of the jury the matter would have been allowed to drop. But events have happened and are happening which tend to prolong a useless controversy and which do not show the morality of an antivivisection society in a very favourable light. Mr. Coleridge was compelled by the verdict of the jury to pay a sum of £2000 damages and also to pay the costs. He thereupon, according to a statement made by his solicitor which appeared in the *Times* of Dec. 2nd, paid over from his private account a cheque for £2000, which cheque was duly sent to the plaintiff's solicitors on Nov. 19th. A paragraph afterwards appeared in the *Manchester Daily Dispatch* to the effect that the National Antivivisection Society had paid Mr. Coleridge's damages and costs. This was the statement which Mr. Coleridge's solicitor wrote to contradict. He added: "Mr. Coleridge also requests me to state that he has no intention of asking the society to contribute in any way to the payment of the damages or any of the legal expenses." As was to be expected, the London correspondent of the *Manchester Daily Dispatch* was not going to allow this traversing of his statement to pass unnoticed and accordingly in the *Times* of Dec. 7th appeared a letter from him inclosing for the information of the editor of the *Times* a circular sent out from the National Antivivisection Society under date Dec. 1st appealing for subscriptions to defray Mr. Coleridge's expenses and damages. The society also wrote on Dec. 2nd to the correspondent of the *Manchester Daily Dispatch* asking him to contradict a statement in which there was no word of truth and stating, moreover, that not only had the society not paid the costs and damages but that it had no intention of doing so. Mr. Coleridge may not have asked his society to pay his damages and costs but it is quite evident either that the society is distended bladders—a process, however carefully done, liable to lead to cystitis and pyelo-nephritis with possibly a fatal result—Dr. Cabot has found that permanent drainage at the onset of the cystitis was most beneficial. He now prefers to establish at once constant drainage of a distended bladder rather than to attempt intermittent catheterisation. Thus the risk of pyelo-nephritis following is greatly diminished. The question arises, How long shall catheter drainage be continued? Dr. Cabot's rule is to continue it until all symptoms have disappeared and the urine has become almost normal. If on attempting to discontinue it fever returns and the quantity of urine diminishes he concludes that the ureteric orifices have not recovered their valvular condition and that irritation of the kidneys has again been produced by backward flow of infected urine from the bladder. Probably, also, increase of tension plays a part. In such a case drainage should be again established not only till symptoms disappear but for a much longer time. Then another attempt may be made and if the condition of the kidneys is prone to relapse the change should be made gradually.

VICTORIA UNIVERSITY OF MANCHESTER: ADVANCED LECTURES ON PUBLIC HEALTH.

A SERIES of advanced lectures intended for medical officers of health will be delivered during the months of January, February, March, May, and June at the Victoria University of Manchester. These lectures, primarily intended for medical officers of health and medical men who are members of sanitary committees or who are candidates for diplomas in public health, are also open with certain formalities to others interested in sanitary matters. The syllabus for the coming session includes the following well-known sanitarians and public health authorities and we have placed the subjects on which they are announced to lecture next their names:—Professor Thomas Oliver, Industrial Diseases due to Poisonous Gases; Professor J. Lane Notter, Spread of Typhoid Fever, Dysentery, &c., with special reference to Military Tropical Life; Dr. James Niven, Feeding in Relation to the Health of the Young; Dr. S. Monckton Copeman, Vaccination, its Pathology and Practice; Dr. Arthur Newsholme, the Rôle of Unsuspected Cases in the Spread of Infectious Diseases; Mr. Gilbert Fowler, D.Sc., Chemistry of the Bacterial Treatment of Sewage; Dr. J. C. Thresh, Water Filtration; Dr. H. T. Bulstrode, Relations of Shell-fish to Disease; Dr. T. E. Hayward, the Construction of Life Tables, with Special Reference to Phthisis; Dr. John Robertson, Atmospheric Carbonic Acid, its Origin and Variation; and Mr. Francis Vacher, Defective Sanitary Appliances. Those who wish to attend this course of lectures should send their names with qualifications and address to Professor S. Delépine, Director of the Public Health Laboratory of the Victoria University of Manchester, 1, Stanley-grove, Manchester, who will supply any additional information.

INTRACTABLE CONSTIPATION.

A NEW method of dealing effectually with cases of intractable constipation has been devised and successfully carried out by Mr. W. Arbuthnot Lane. We have already published[1] the views held by Mr. Lane concerning the condition of intestinal obstruction that results from the development of adhesions round the large gut in persons suffering from chronic constipation. Mr. Lane has operated on some cases for obstruction alone with the result that though the adhesions were freely divided at the time of operation the trouble recurred. Mr. Lane therefore thought of the plan of effecting a lateral anastomosis between the end of the ileum and the first piece of the rectum. By this means a free passage is made between the small gut and the rectum and the sluggish course of the fæces through the large gut is avoided. In a case lately operated on by Mr. Lane the conditions calling for the operation were well exemplified. The patient was anxious for the first operation because of the pain and tenderness which the obstruction produced. The adhesions were divided on four occasions, but in spite of frequent and immediate purgation the adhesions re-formed and the symptoms recurred. The several operations were undertaken at the patient's urgent request. All these four operations were of the same nature and the method detailed of connecting the ileum with the rectum was then proposed and carried out with the satisfactory result that the patient was relieved from pain and freed from the intolerable suffering that accompanied the condition for which she originally sought relief by operation. By connecting the ileum to the rectum the whole of the large intestine above this portion of the bowel was no longer in use. The patient was completely relieved of pain and tenderness, she lost the toxic symptoms and physical depreciation due to the long continuance of the fæces in the large bowel, and her intestines reacted readily to mild purgatives.

CULTIVATION OF A TRYPANOSOMA.

THE extreme difficulty or impossibility of artificially cultivating the protozoa in a pure state—i e., free from bacterial or other contamination—has been a great hindrance to the study of the parasitic forms. The announcement, therefore, that Mr. W. J. McNeal and Dr. F. G. Novy have succeeded in cultivating the trypanosoma of the rat (trypanosoma Lewisi) is of considerable interest.[1] The medium employed was composed of agar to which was added defibrinated blood, usually of the rabbit, obtained with aseptic precautions. The hæmoglobin seems to be an important constituent. Ordinary nutrient agar is prepared, filled into tubes, and sterilised. After the last steaming the tubes are allowed to cool to 50° C. and about one-third of the volume of the defibrinated blood is added. The tubes are then placed in the sloping position and the medium is allowed to solidify. The condensation water in the tubes is inoculated with loopfuls of blood obtained from an infected rat and the tubes are incubated either at room temperature or at blood heat; at the former development is slow and at the latter fairly rapid. 11 passages from tube to tube were made in the course of a year, incubating at room temperature, and some of the fluid from the tenth generation proved to be still virulent for rats. Incubating at blood heat 22 passages were made in six months and the twentieth generation also proved virulent. Modifying the culture medium by the addition of glycocoll and sodium asparaginate the trypanosoma was kept alive in one tube for no less than 306 days. More recently the same investigators have succeeded in cultivating the trypanosoma of nagana (trypanosoma Brucei) in a similar manner, though it proved much more difficult to carry out.

THE medical officer of health of Cape Colony states that for the week ending Nov. 14th only one case of plague occurred throughout the Colony, being that of a native child at East London. Plague infected rodents were discovered during the week at Cape Town, Lady Grey Bridge, Knysna, and Port Elizabeth. As regards the Mauritius a telegram from the Acting Governor received at the Colonial Office on Dec. 4th states that for the week ending

[1] THE LANCET, Jan. 17th, 1903, p. 153.

[1] "Contributions to Medical Research by Colleagues and Former Students" Dedicated to V. C. Vaughan. Ref. in the Bulletin de l'Institut Pasteur, vol. i., No. 16, 1903, p. 602.

Dec. 3rd there were 60 cases of plague and 41 deaths from the disease.

THE annual lecture under the endowment of the Richard Middlemore Post-Graduate Lectures will be delivered at the Birmingham and Midland Eye Hospital by Mr J. Jameson Evans, surgeon to the hospital, on Friday, Dec. 18th, at 4.30 P.M. The subject chosen by the lecturer is Bacterial Diseases of the Conjunctiva and there will be a clinical and microscopical demonstration after the lecture. All members of the medical profession are invited to attend.

A PAPER is to be read to-night (Friday) at the meeting of the Epidemiological Society at 11, Chandos-street, London, W.C., by Dr. Louis Sambon on Sleeping Sickness. The paper of Dr. Sambon, who is a lecturer at the London School of Tropical Medicine, may lead to an interesting debate if, as expected, Professor Ray Lankester, Sir Patrick Manson, Lieutenant-Colonel David Bruce, R.A.M.C., and Dr. Adolph Castellani are present.

THERE will be no measure introduced in Parliament next session to provide for revaccination. The Government appear to have found out at the last meeting of the Cabinet that their hands were too full to permit of the introduction of the Bill. Whether it will strengthen an administration whose best friends cannot describe as robust thus to shelve a necessary and promised piece of legislation is, to say the least, doubtful.

THE announcement is made that His Majesty the King has accepted an offer from Mr. John Brickwood to build a church for the Royal Sanatorium at Midhurst. The cost is estimated at £20,000. This may appear a late addition to the original scheme, but a place of worship was specifically omitted from the plans which obtained the first prize in the competition for reasons which Dr. A. Latham, the winner, gave.

THE FINAL REPORT OF THE ROYAL COMMISSION ON ARSENICAL POISONING.

I.

THIS report has now been issued as a Parliamentary paper.[1] It is a document of 50 pages and is signed by all six Royal Commissioners, Lord Kelvin (chairman), Sir William Hart Dyke, M.P., Sir William S. Church, K.C.B., Dr. T. E. Thorpe, F.R.S., Mr. H. Cosmo Bonsor, and Dr. A. Whitelegge, C.B. Dr. G. S. Buchanan, of the Local Government Board, acted as secretary to the Commission. It is stated that two volumes will shortly be issued, comprising the evidence received by the Commission and also various supplementary papers and reports of scientific inquiries which have been undertaken. In the present article, and in another which will appear in a subsequent issue, we propose to give an account of some of the principal points dealt with in the report.

The main circumstances which led to the appointment of the Commission in February, 1901, are sufficiently familiar. At the end of November, 1900, it became known that for several months large and continually increasing numbers of patients suffering from peripheral neuritis had been admitted to Manchester hospitals and Poor-law infirmaries and that Dr. E. S. Reynolds of Manchester had established that the cause of this occurrence and also of the prevalence of some other forms of illness was the presence of arsenic in beer—a fact which was confirmed by independent inquiries made by Mr. C. H. Tattersall, medical officer of health of Salford, and by several other investigators. Almost at once it was realised that this epidemic of arsenical poisoning was spread over many parts of Lancashire, Staffordshire, and elsewhere in the north and midlands and it was shown that in all cases the origin of the considerable quantities of arsenic found in the beer was "brewing sugar," sold by the Garston firm of Bostock and Co., which had been prepared by the use of an arsenical sulphuric acid manufactured by the firm of Nicholson and Sons of Leeds. Valuable reports on inquiries made in consequence of the epidemic were issued by medical men and chemists, particularly Dr. J. Niven, Dr. E. W. Hope, Mr. Tattersall, Dr. G. Reid, and Mr. E. Sergeant, by a strong "expert committee" appointed by the Manchester brewers, and by Dr. Buchanan on the result of inquiries made on behalf of the Local Government Board. These inquiries brought into prominence a state of affairs which on all hands was recognised as unsatisfactory: uncertainty, for example, regarding the extent of the epidemic, the share which malt and other ingredients of beer might have had in producing the recent poisoning by arsenic, the tests for arsenic most suitable for use by public analysts and brewers' chemists, and the risks of arsenical contamination in the case of other articles of food or drink. Moreover, they showed the necessity of thorough investigation of a number of important questions which had arisen in consequence of the demonstration afforded by the epidemic of the defects in the present laws relating to food and in existing administration under the Sale of Food and Drugs Acts. The Royal Commission which was consequently appointed at the instance of the President of the Local Government Board was given a wide reference covering these and other matters. The Commission issued an interim report in July, 1901, on which we commented at the time, setting out the results of its inquiries up to that date and the directions in which it was proposed to undertake further work, while making an interim recommendation for the exercise of control by the Board of Inland Revenue over arsenic in beer ingredients. It is evident that the investigation which has followed during the past two years has been thorough and comprehensive. The final report is divided into the following parts:—

1. Further observations regarding the epidemic of arsenical poisoning in 1900 and as to the medical and public health aspects of the evidence received regarding arsenic in beer and food.
2. The suggested relation between the disease "beri-beri" and arsenical poisoning.
3. Tests for arsenic in foods and substances used in the preparation or manufacture of food.
4. Ways in which foods are liable to become contaminated by arsenic.
5 Precautions which should be taken by manufacturers to exclude arsenic from foods.
6 Present means of official control over purity of food in relation to arsenic.
7. Recommendations as to improvements in official control over the purity of food.
8. Recommendations as to the proportions of arsenic in food which should now be held to constitute an offence under the Sale of Food and Drugs Acts.

The report has evidently been very carefully arranged and worded and its argument is so much condensed that it is by no means easy to abstract. In the present article we summarise some of the principal matters dealt with in Parts 1 to 3.

After briefly recalling the circumstances of the Bostock-Nicholson occurrence and the steps taken by public health authorities and by brewers to put an end to the outbreak of poisoning in 1900 the Commission reports the action which it took to secure that some 700 tons of arsenical glucose and "invert sugar" remaining at the works of Bostock and Co. after the company had gone into liquidation were disposed of for textile and other purposes unconnected with food. The danger of poisoning which arose through the use of arsenical sulphuric acid by this firm was not restricted to brewing sugars. In 1900 Messrs. Bostock and Co. had begun to manufacture preparations resembling treacle termed "table syrups"—sugar which had been "inverted" by Nicholson's sulphuric acid, flavoured with various fruit essences, and put up in two-pound tins for sale. The contents of some of these tins, examined by Dr. G. McGowan, D.Sc., showed about one grain of arsenic per pound. Fortunately, at the date of the discovery of arsenic in the firm's brewing sugars scarcely any of these syrups were on the market, as a trial series of tins sent out to retailers had not proved a success commercially on account of an accident in manufacture which led to the syrups crystallising. 14 tons of these tins were ultimately burnt by order of the liquidators.

Extent, Distribution, and Fatality of the Epidemic of 1900.

Information on these points was obtained by the evidence of witnesses and by circular letter addressed to medical officers of health throughout the country. No cases were reported from the southern or eastern counties, from London, or from 37 English county boroughs; the districts affected were in nearly all cases in the north-west and midlands. Lancashire and Staffordshire suffered most severely. Medical officers of health, in giving estimates of the number of cases which occurred in their districts, were in many instances careful to point out that there must have been others which did not come to their notice, and the Commission concludes that the total of persons attacked "was certainly 6000 and probably the number was, in fact, very considerably greater." It was impossible to determine the fatal cases with any approach to accuracy. A total of 70 deaths occurred in which arsenical poisoning was entered on the death certificate as one of the causes of death or was found to be the cause of death as the result of a coroner's inquest, but the deaths so certified did "not represent the total number of cases in which death resulted from, or was accelerated by, poisoning due to arsenic in beer. Deaths occurring before the discovery of the cause of the outbreak were frequently certified as due to 'chronic alcoholism' and 'cirrhosis of the liver,' and in some cases were attributed to Addison's disease and locomotor ataxy. Other deaths were recorded as due to 'alcoholic,' 'peripheral,' or 'multiple' neuritis." Owing to [illegible]

be made by comparing the deaths in 1900 with those of previous years.

Effect of the Epidemic on the Birth-rate.

Reference is made to statistics furnished by Dr. Niven, medical officer of health of Manchester, which suggest that a strongly marked fall in the birth-rate of Manchester, Salford, and Liverpool in the third quarter of 1901 was attributable to the epidemic. These statistics, which include comparison with other large towns unaffected by the epidemic, will be studied with interest when the volumes of evidence of the Commission appear. The fact, if established, would accord with observations made by Brouardel and others on anaphrodisia and impotence resulting from long-continued doses of arsenic.

Symptoms of Poisoning due to Arsenic in Beer during the Epidemic of 1900.

The report points out that—

> There were great differences in individual cases as regards the quantity of arsenic in the beer consumed, the amount of beer taken, and the duration of the period over which arsenical beer was drunk, and there were also further differences between individual beer-drinkers—e.g., as to age, sex, health, *conditions of nutrition*, and habits as regards alcohol—which determined the extent of their susceptibility to arsenical poisoning at the time when they began to take beer containing arsenic. ...... Corresponding to these and other differences, the disease produced by the arsenical beer during the epidemic varied greatly in its manifestations. On the one hand, there occurred throughout the epidemic (and particularly, it would seem, towards its termination, when people had been drinking arsenical beer for many weeks or months and so had taken considerable quantities of the poison) an abundance of cases in which, once the possibility of arsenic was entertained, there was comparatively little difficulty in deciding on clinical grounds that the illness was consistent with arsenical poisoning. Such cases presented symptoms *corresponding to those* described as characteristic of subacute poisoning by arsenic, or which are met with i[illegible] results from long-continued doses [illegible] example, inflammatio[illegible] huskiness, lacrymatio[illegible] and diarrhœa; periphe[illegible] and in some cases [illegible] erythromelalgia, keratosis, or recent pigmentation corresponding to that which not infrequently occurs in persons taking arsenic for long periods.
>
> On the other hand, symptoms of the above kind were often slight [illegible] instructive points in con[illegible]ses in which the [illegible] owing evidence of [illegible] symptoms point- [illegible] lly identical with [illegible] to be the result, alike in drinkers of beer and spirits, of the toxic action of alcohol on *nerve tissue.*

The latter considerations are of considerable importance in relation to the argument, subsequently developed in the report, that even minute quantities of arsenic should be excluded from food. In an epidemic such as that in Manchester, when once the *fact of arsenic in beer* was known a great deal of anomalous illness was explained. But in every-day practice, without an epidemic or other circumstances to suggest arsenic, the true nature of such cases (and especially of the slighter forms of poisoning) would very seldom be capable of being satisfactorily established.

Poisoning from Arsenic in Beer apart from the Epidemic of 1900.

The report gives a good deal of space to the question of arsenic in its relation to "alcoholic neuritis." The Commission is satisfied that before 1900 medical men in Manchester and other places were much more familiar with "alcoholic neuritis" than was the case in London, Scotland, and large centres of population in the south of England, and this view is confirmed by the comparative data obtained from hospitals. It is observed that in the former places the disease had been recognised (for some years before 1900 and the "Bostock-Nicholson" incident) as one which affected beer-drinkers far more than spirit-drinkers. Malt has now been shown to be liable to contain material quantities of arsenic, especially when dried by exposure to the products of combustion of gas coke. Manchester and Liverpool brewers who gave up the use of Bostock's and other brewing sugars found, nevertheless, that they could not produce beer which could be regarded as practically free from arsenic until they had discontinued the use of malt which had been dried over this fuel. Use of gas coke on the fire of the malt kiln has never been common in the southern and eastern counties, but at Manchester and Liverpool until the 1900 epidemic a large part of the malt used came from Yorkshire and had been dried over local gas coke. Some of these malts after the epidemic were found to contain one-twentieth of a grain and exceptionally even one-sixth of a grain of arsenic per pound, the quantity of malt used to the gallon of beer being usually between one and two pounds. From these considerations the Commission concludes that—

> The fact of greater prevalence of alcoholic neuritis among beer-drinkers in Manchester and Liverpool before 1900, when compared, for example, with London and places in the southern counties, is consistent with the explanation that (whatever may have been the case with regard to brewing sugars) the degree to which beer was likely to become contaminated by arsenic was greater in these two cities owing to the larger proportion of arsenic contained in much of the malt there used.

The report shows that this is confirmed by the evidence which the Commission has received of the marked diminution in "alcoholic neuritis" and in the condition locally known as "alcoholic heart" in Manchester during 1901 and 1902, when compared with other periods before the epidemic year of 1900. This diminution corresponds with stringent and effectual precautions against arsenic which have been taken by Manchester brewers since the epidemic, including the disuse of arsenical malt.

Arsenical Poisoning in Halifax in 1902.

A small but instructive outbreak in Halifax, which was investigated for the Commission by Mr. H. Hammond Smith, and also by Dr. J. T. Neech, medical officer of health of the borough, gives point to these conclusions. Some 15 cases (three of which were fatal) presenting symptoms pointing unmistakeably to arsenical poisoning were discovered in this town early in 1902, the circumstances being first brought to notice by Dr J. F. Hodgson:—

> All the persons attacked were beer-drinkers and in most instances heavy beer-drinkers. There was no reason to suspect that they had received arsenic otherwise than through beer, while there was strong evidence that the beer they had consumed had been arsenical. Samples of beer taken in January, 1902, from public houses frequented by certain [illegible] grain of arsenic per gallon [illegible] the other hand, the facts pointed strongly to the conclusion that the implicated beers had been contaminated by arsenic derived from malt used in *their preparation. In nearly every instance there was* evidence that the malt concerned had been dried over local gas coke and that the brewer, before using it, had taken no precautions to ascertain its condition as regards arsenic. *In most cases the malt* which had been used in the implicated brews had been dried in the [illegible] malting season, 1900-01, over gas coke; and at some maltings [illegible] 902. One [illegible] per cent. [illegible] coke was [illegible] Certain [illegible] which had

been used in the beers under inquiry showed amounts of arsenic such as one-sixtieth of a grain per pound. In one instance where the brewer had used malt in the proportion of two pounds to the gallon of beer, a sample of the beer, taken in January, 1902, was found to contain one-sixteenth of a grain of arsenic to the gallon, and it was shown that on the single occasion on which the maltster had sent a sample of his malt to be examined for arsenic the analyst had reported the presence of as much as one-thirtieth of a grain of arsenic to the pound.

The Commission points to the circumstances of this small outbreak as showing that poisoning by arsenic in beer may even now easily pass undetected, notwithstanding that a number of cases may be occurring in the same place at about the same time, and adds that the Halifax beers associated with the outbreak "must have been typical in respect of arsenic of a large class of beers prepared before the 1900 epidemic from arsenical malt."

Alcoholic Neuritis apart from Arsenical Poisoning.

On this subject the Commission states :—

> In our view it is important that the question of arsenic should be fully considered in all cases of peripheral neuritis attributed to beer-drinking. To what extent beer free from arsenic is capable of producing neuritis among heavy drinkers the data at our disposal do not suffice to permit an opinion to be given. We are unable to accept the thesis of some witnesses that there is, practically speaking, no "alcoholic neuritis" apart from arsenic. Inquiries which we have made as to the experience of London and provincial hospitals show that cases of alcoholic neuritis are met with from time to time in which the alcoholic liquor consumed has been exclusively spirits. All the evidence adduced is to the effect that spirits are not liable to contain arsenic.

As regards arsenical beer, "it may be conjectured that when small doses of arsenic are taken for a long time, together with considerable quantities of alcohol, the arsenical poisoning liable to result will be manifested more frequently and more conspicuously by peripheral neuritis than if the arsenic had been taken without the alcohol." Although it is possible that arsenic may enter into some combination with the organic matter of beer the chemical evidence is inconclusive and the Commission sees no reason to assume from merely clinical data that poisoning by arsenious oxide in beer is itself insufficient to explain the morbid conditions observed. Professor Delépine and others have shown that there is no evidence that cacodyl or substances akin to cacodyl are formed in arsenical beer.

The rest of Part I. deals with the evidence as to individual susceptibility to arsenic, accumulation of arsenic in human tissue, and ways in which arsenic is eliminated. It is obvious that the Commission has received a large amount of valuable information on these points and its evidence when published should provide a store of useful material for reference. An investigation into the elimination of arsenic by the hair, which the Commission undertook with the assistance of the medical registrars of certain London hospitals and the medical superintendents of certain London infirmaries, is summarised in the final report, and the complete account of this inquiry, which appears to have shown that the hair may give clear indications of arsenic when as little as one-twentieth or one-thirtieth of a grain has been taken daily for two months, will be awaited with interest.

Importance of the Exclusion of Small Quantities of Arsenic from Food.

Under this heading the report deals with the general trend of the evidence on the subject; as to individual susceptibility, the possibility of arsenic being received at the same time from more than one source of food or drink, the difficulty of ascertaining the true nature of milder forms of arsenical poisoning occurring in isolated instances, and the toxic effect of small doses of arsenic administered over long periods to rodents.

> The question has often arisen, with reference to particular foods liable to contain a relatively minute quantity of arsenic, whether such a quantity may not be regarded as unimportant and altogether negligible and the Commission have, as it were, been challenged to say that it can do no harm.

But reasons are given for not accepting this position.

> We adhere to the view expressed in our first report that it would be unwise to express an opinion that any quantity of arsenic, however small, is to be regarded as admissible in any articles of food, and we think it should be the aim of the food manufacturer to exclude arsenic altogether from his products.

Relation between Beri-beri and Arsenical Poisoning.

This question has been investigated by Dr. Herbert Williams, Mr. C. C. Bullmore, and other port medical officers of health, who have ascertained particulars regarding cases of beri-beri on vessels arriving at London, Falmouth, and elsewhere, and have collected specimens for analysis by Dr. McGowan on behalf of the Commission. In promising a detailed account of the information thus obtained the report states :—

> In a few instances the results gave some ground for inference that the beri-beri cases inquired into had lately been taking arsenic along with their food. Thus the hair of one or two of the patients contained noteworthy amounts of arsenic, while small quantities of arsenic were found in several samples of dried fish—an important article in the diet of sailors on Scandinavian sailing ships. But when such clinical, etiological, and chemical data as we have been able to collect are considered as a whole, they cannot be said to support the view that cases of beri-beri met with on ships arriving at home ports are essentially attributable to poisoning by arsenic.

Tests for Arsenic in Food and Substances used in the Preparation and Manufacture of Food.

All who have followed the "arsenic question" during the past two years will be aware of the great difficulties which arose, particularly at first, in obtaining satisfactory methods of estimating minute quantities of arsenic in organic substances. The Commission has received a great deal of chemical evidence, especially from two strong committees, one a joint committee of the Societies of Public Analysts and Chemical Industry, with Mr. Otto Hehner as chairman, and the other, with Dr. Thorpe as chairman, appointed by the Board of Inland Revenue to advise as to arsenic in beer ingredients. The report deals with the essential principles of applying what is now termed the "Marsh-Berzelius test' to various substances. In this test, as is well known, the arsenic from the arseniuretted hydrogen is deposited, not on a porcelain tile, as in the "Marsh" test, but in a capillary tube. Within a certain range "mirrors" of arsenic deposited in these tubes show definite differences in intensity according to the quantity of arsenic present and an estimation is made by comparing the intensity of the mirror obtained from a given weight of substance with a set of standard mirrors. Attention to various points of detail is essential to accuracy. In nearly all cases it is necessary in the first instance to destroy completely any organic matter present. The presence of iron salts in the Marsh apparatus may seriously vitiate the result. It is not only necessary to have zinc which is free from arsenic but also zinc which is "sensitive" and does not retain the arsenic in the solution tested. The Commission finds that chemists are now agreed as to these and other sources of error which it is necessary to avoid and that if due regard is had to these points differences as small as 0·2 part of arsenic per 1,000,000 in the substance taken, or 0·0014 grain of arsenic per pound, can be readily distinguished. When various substances are taken for analysis in quantities which have been found practically convenient the presence of arsenic will be detected when in amounts well below one-thousandth of a grain per pound, or in the case of a liquid well below one three-hundredth of a grain per gallon. The departmental committee has found that in the case of beer ingredients many of the difficulties attending the Marsh-Berzelius test are obviated by an electrolytic method of evolving arseniuretted hydrogen, which can be applied wherever a current of sufficient intensity is available. Wide experience of the working of this method may soon be looked for.

THE LONDON SCHOOL OF TROPICAL MEDICINE; ITS ACHIEVEMENTS AND REQUIREMENTS.

Sir Patrick Manson, M.D., F.R.S., gave an excellent address on Monday last, Dec. 7th, at the London School of Tropical Medicine, Seamen's Hospital, Royal Albert Dock, E., on the Achievements and Requirements of the School. A distinguished company was present to hear the address and to wish Sir Francis Lovell, the dean of the school, godspeed in his self-imposed task of paying another visit to the East to collect funds to carry on the work.

At the commencement of his address Sir PATRICK MANSON said that he wished to make public acknowledgment of the obligations of the London School of Tropical Medicine to Mr. Chamberlain, the late Colonial Secretary, who had been the mainspring of the movement for education in tropical medicine, and to the Seamen's Hospital Society and its governing body who supported Mr. Chamberlain's scheme. In a hundred ways it had been helping forward the good work. As regards the educational work of the school

Sir Patrick Manson said that since the school opened on Oct. 3rd, 1899, over three hundred students had passed through its portals. During the first two years (six sessions) they had had 149 students; during the last two years (six sessions) they had had 178 students. In the earlier days of the school's existence many of the students came for one or two months only. Now a large proportion of the students remained during the full course of three months. When they left the majority of the students had a genuine practical grasp of their subject. They had seen and most of them had applied for themselves the most recent methods of diagnosis, and as far as teaching and opportunity could insure they were qualified for medical work in the tropics—qualified both to practise their profession and to advance the science of tropical medicine. Where two or three men took a languid interest in tropical disease some five or six years ago, a whole army of eager investigators had arisen, mainly composed of men educated or inspired by the London and Liverpool schools of tropical medicine. This multiplication of investigators had already borne remarkable fruit. Without alluding to what had been done in Liverpool he could point out not a few notable triumphs by men from the London school, although the school had been in existence for only just over four years. He instanced Dr. G. C. Low's work in connexion with the etiology of elephantiasis; the practical experiment of Dr. L. Sambon and Dr. Low as to the spread of malaria by mosquitoes; the discovery in the Gambia colony by a pupil of the school of a new blood parasite which was subsequently recognised by Dr. J. E. Dutton of the Liverpool School of Tropical Medicine; and the demonstration by Dr. A. Castellani, another pupil of the school, of the association of this same parasite, a trypanosoma, with sleeping sickness. Sir Patrick Manson added here that the certainty of this trypanosoma being the cause of sleeping sickness had, through the clinical opportunities of their school and hospital, now been proved. There were other discoveries which might be accredited to the school, but those which he had mentioned were sufficient to indicate that their existence had not been unproductive and that the few thousand pounds which the establishment had cost the country had been well invested. The permanent additions to human knowledge made by the workers [illegible] while he [illegible] Craggs, [illegible] nable for three years, for purposes of research. He had also made a very handsome annual donation to be awarded to any actual or past student of the school who, during any current year, should make an important contribution to tropical medicine. In referring to beri-beri Sir Patrick Manson said they did not despair of getting light on this disease. Dr. C. W. Daniels, their late superintendent, had been placed in charge of the research laboratory at Kuala Lumpur, and in the Federated Malay States beri-beri was rampant. Perhaps no country in the world, he thought, was so likely to benefit by recent advances in tropical medicine as the British colonies and protectorates in the Malay Peninsula, for beri-beri was a terrible drag on the mining and agricultural industries there. The school had expressed its gratitude to the Hon. Bomanji Dinshaw Petit who gave the school 100,000 rupees, but when he thought of the wealth that many Chinese had accumulated under the British flag in the Straits of Malacca he was not without hope that Sir Francis Lovell in his excursion to the East would find a Chinese rival to Mr. Petit.

After paying an eloquent tribute to the energy and unselfishness displayed by Sir Francis Lovell in his work for the school, Sir Patrick Manson concluded by an appeal for public support. At the present time, he said, the school had certain schemes of investigation before it for some of which they wanted money, for others men and money. They wished to furnish their museum and library on a scale adequate to the needs of the school. In short, they wanted £100,000, or as much of that sum as they could get. Any one of the discoveries which he had mentioned, said Sir Patrick Manson, was worth the sum he had named ten times over, apart from the education which the school had supplied to its students. They had given the public a great deal more than they had ever received, or would ever be likely to receive, and therefore they had no hesitation in asking for something more on account. The teachers were strictly honorary, their pay was so small that the laboratory microscopes were sometimes required to see it. They had the approval of those best qualified to judge of the work the school had undertaken—viz., the medical profession, whose hearty practical sympathy was peculiarly gratifying to them. Finally, Sir Patrick Manson said that "he who gives to the London School of Tropical Medicine lends to humanity."

On the motion of Sir William S. Church, seconded by Sir F. Young, a vote of thanks was heartily passed to Sir Patrick Manson for his address.

MEDICINE AND THE LAW.

The Law relating to Experiments on Animals.

The recent libel action against the honorary secretary of the National Antivivisection Society was fought upon the issues raised upon the pleadings and so resolved itself into the question whether the dog experimented upon was under the influence of anæsthetics or was cruelly and recklessly operated upon without them. This was the substance of the libel, but the defendant's counsel in the course of the trial raised two questions as to the legality of the experiments performed which were not relevant because the libel contained no allegation with regard to them and which consequently were not decided either by judge or jury. These were (1) whether the demonstration performed by Mr. W. M. Bayliss before the students whom he was lecturing was permissible under the Act; and (2) whether the dog used for this demonstration should have been so used taking into consideration the fact that it had already had its abdomen opened for the purpose of examination by Dr. Starling. Both these questions are regulated by the same section of the Act (39 & 40 Vict. c. 77, Sec. 3). With regard to the first, which is the more important of the two to those engaged in the instruction of students, this section says: "The experiment shall not be performed as an illustration of lectures in medical schools, hospitals, colleges, or elsewhere," provided that "experiments may be performed under the foregoing provisions as to the use of anæsthetics by a person giving illustrations of lectures in medical schools, hospitals, or colleges or elsewhere, on such certificate being given as in this Act mentioned that the proposed experiments are absolutely necessary for the due instruction of the persons to whom such lectures are given with a view to their acquiring physiological knowledge which will be useful to them for saving or prolonging life or alleviating suffering." It will be seen that the important question here is the scope of the expression "absolutely necessary for the due instruction" of students in physiological knowledge such as will be useful to them in the medical profession, and that the application of the section to particular experiments must be, to some extent, a matter of opinion. At any trial arising out of an alleged infringement of this portion of the Act it would be a question of fact whether a particular experiment was necessary for due instruction. A jury would have to decide this if the case was being tried with a jury and the jury would have to base its decision upon evidence given on oath before it. The best obtainable witnesses as to this would be persons engaged in the instruction and examination of students, as it is submitted that their views would naturally and properly carry the greatest weight both as to the assistance given to instruction by actual demonstration and as to the need of accurate knowledge of the phenomena demonstrated by those desiring to "prolong life and alleviate suffering." The evidence of eminent men engaged in the practice of medicine and of surgery would be of almost equal importance and the court would no doubt listen to the opinion of any medical man who was called as a witness subject to such comment as might be made upon his qualification to speak with authority. The evidence given on behalf of Mr. Bayliss was precisely such as has been indicated above and had the issue in question been before the jury the evidence upon it could no doubt have been increased in quantity, although in quality it could hardly have been strengthened. The matter is one which no doubt throws considerable responsibility upon the teacher who has to exercise his discretion in the selection of his illustrations. He is, however, subject to the supervision imposed by the Act and this is in itself a protection to him. It is clear that the Act contemplates the use of live animals for purposes of instruction, and as only ascertained truths are required to be inculcated by teachers it must also be held to have contemplated the employment of animals for the demonstration of ascertained truths. The fact that the result of the experiment made use of at University College might have been described orally with the aid of diagrams or models was urged repeatedly during the hearing of Bayliss *v.* Coleridge. It is conceded that all scientific facts can to some extent be imparted without actual demonstration; it is the question of the degree to which such demonstration is desirable and the circumstances in which it is necessary upon which physiologists and "antivivisectionists" will continue to differ. If the question is removed from the debateable ground of physiology to that of chemistry few will be found to say that demonstration is unnecessary for instruction simply because the consequence that will follow the experiment has been reduced by previous trials to a matter of certainty. It must also be remembered that the standard imposed by the words "due instruction" is not a fixed one. The "due instruction" of students varies not only from century to century but from generation to generation and from decade to decade, and the public who alone gain by the advances of science and by the improvement in teaching in our medical schools will not be anxious to impose restrictions for which no need is shown. With regard to the second question, as to the repeated use of the same dog, "the animal must, if the pain is likely to continue after the effect of the anæsthetic has ceased, or if any serious injury has been inflicted upon the animal, be killed before it recovers from the influence of the anæsthetic which has been administered," provided that "experiments may be performed without the person who performed such experiment being under an obligation to cause the animal on which any such experiment is performed to be killed before it recovers from the influence of the anæsthetic on such certificate being given as in this Act mentioned, that the so killing the animal would necessarily frustrate the object of the experiment, and provided that the animal be killed as soon as such object be attained." In the course of Bayliss *v.* Coleridge it was proved that Dr. Starling performed an experiment upon a dog which he was entitled under the Act to perform and afterwards kept it alive as he was entitled under the Act to do. He at a later date anæsthetised it and made an examination of the result of his previous experiment which again he had a perfect right to do. He then according to the "antivivisectionist" contention should have killed the dog, instead of which, while it was still in a state of anæsthesia he allowed Mr. Bayliss to use it for a demonstration entirely distinct from the experiments made already upon it. Dr. Starling pointed out that the animal was already completely unconscious and destined never to return to consciousness and that the alternative was to take a fresh dog for the purpose of Mr. Bayliss's lecture. This has been represented in various "antivivisectionist" articles in newspapers and elsewhere as a desire to economise dogs, or, rather, to save the price of them. Such nonsense carries its own refutation on the face of it. It may be contended that Dr. Starling and Mr. Bayliss committed a technical infringement of the Act under which they performed their experiments. If they did so neither they nor any other physiologists need repeat their offence now that attention has been called to the point, and in this respect the effect of Bayliss *v.* Coleridge will be that a few more animals will be used in the performance of experiments in the course of each year than would otherwise have been the case, a curious result for an "antivivisectionist" society to have brought about. The amount of pain inflicted upon animals will be neither diminished nor increased.

Insanity in the Eye of the Law.

In a trial for murder at the recent Derby assizes Mr. Justice Channell told the jury that the prisoner might be insane and still be responsible at law for what he had done He called their attention to the answer given by the judges in M'Naughton's case. where it was said that "if the accused was conscious that his act was one which he ought not to do and if that act was at the same time contrary to the law of the land he was punishable," and where it was further pointed out that the usual course was "to leave to the jury the question whether the party accused had a sufficient degree of reason to know that he was doing an act that was wrong, with such observations and explanations as the circumstances of each particular case might require." Mr. Justice Channell added that his own practice was to lay down the law slightly more in favour of the prisoner by adding that if from disease of the mind a person was unable to consider what was the difference between right and wrong, then it might fairly be said that he did not "know" the difference between right and wrong. He added that mere insufficiency of motive was not to be relied upon as evidence that the prisoner did not know that he was doing wrong. In the case which his lordship was summing up a labourer, aged 25 years, had murdered a girl, a domestic servant at a farm where he was wagoner, by cutting her throat and had then attempted his own life in the same way. His own story as to motive was that she had "deceived" him and told him that she had "led him on for a bit of fun." There was evidence of several cases of insanity having occurred among the prisoner's relatives, descendants of his maternal great-aunts, and also that he had had an insane great-aunt, but no ancestor was proved to have been insane. The prisoner himself was stated to be deficient in intellect and the learned judge so described him to the jury but asked them to satisfy themselves before acquitting him that his mental condition was such when he did the act as to prevent him from judging whether he was doing wrong. The jury convicted the prisoner but recommended him to mercy, and *sentence of death was passed.* In these circumstances it will not be surprising if the clemency of the Crown is exercised, but at the same time it may confidently be said that if the sentence is carried out it will be after full and sufficient investigation. The degree of responsibility for criminal acts that should be exacted from those describable as mentally deficient must depend upon the consideration of each case and must also to a great extent be a matter of individual opinion. It is unfortunate that the conviction of prisoners so deficient should inevitably depend upon the varying views entertained by jurors, often after hearing conflicting evidence, and still more upon the varying degree of influence exercised by the judge who may either be willing to undertake an admittedly onerous responsibility or may shrink from doing so. This circumstance introduces an element of chance and uncertainty which is very undesirable.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8107 births and 5364 deaths were registered during the week ending Dec. 5th. The annual rate of mortality in these towns, which had been 17 9, 17·4, and 17·6 per 1000 in the three preceding weeks, further rose last week to 18·6 per 1000. In London the death-rate was 17 8 per 1000, while it averaged 18·9 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7 4 in Kings Norton, 10·3 in Grimsby 10·6 in Hornsey, 10·8 in Walthamstow, 11·1 in Reading, 11·4 in Tottenham, and 11 8 in East Ham and in Handsworth; the highest rates were 25 5 in Walsall. 27 5 in Warrington, 27·7 in Bury, 29·2 in Bootle, 29·9 in York, 30·2 in Middlesbrough, 30·5 in Hanley, and 34·4 in Wigan. The 5364 deaths in these towns last week included 402 which were referred to the principal infectious diseases, against 432, 436, and 430 in the three preceding weeks; of these 402 deaths, 102 resulted from measles, 87 from whooping-cough, 72 from diarrhœa, 55 from diphtheria, 43 from scarlet fever, 40 from "fever" (principally enteric), and three from small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Reading, Northampton, Handsworth, West Bromwich, Aston Manor, Halifax, or South Shields; the highest death-rates from the principal infectious diseases were recorded in Willesden, Warrington, Bury, Preston, Rotherham, York, Sunderland, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Willesden, Stockport, Warrington, Bury, Salford, Preston, Rotherham, York, and Sunderland; from scarlet fever in Merthyr Tydfil; from diphtheria in Great Yarmouth and St. Helens; from whooping-cough in Walsall, Bootle, York, and Merthyr Tydfil; and from diarrhœa in Stockport. The mortality from "fever" showed no marked excess in any of the large towns. Two fatal cases of small-pox were registered in Gateshead and one in Manchester, but not one in any other of the 76 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 51, 47, and 40 at the end of the three preceding weeks, had further declined to 35 at the end of last week; three new cases were admitted during the week, against 16, five, and five at the end of the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, Dec. 5th, was 1715, against 1824, 1832, and 1770 on the three preceding Saturdays; 161 new cases were admitted during the week, against 185, 191, and 157 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 339, 325, and 399 in the three preceding weeks, declined again last week to 358 and were 68 below the number in the corresponding period of last year. The causes of 67, or 1·2 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Leicester, Nottingham, Leeds, Newcastle-on-Tyne, and in 44 other smaller towns; the largest proportions of uncertified deaths were registered in Norwich, Birmingham, Liverpool, St. Helens, Warrington, Manchester, Sheffield, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·4, 17·4, and 18·7 per 1000 in the three preceding weeks, further rose to 20·0 per 1000 during the week ending Dec. 5th and was 1 4 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·4 in Perth and 13·2 in Paisley to 23·3 in Greenock and 24·0 in Dundee. The 655 deaths in these towns included 22 from measles, 12 from diarrhœa, seven from whooping-cough, five from "fever," four from diphtheria, two from small-pox, and one from scarlet fever. In all, 53 deaths resulted from these principal infectious diseases last week, against 49, 61, and 62 in the three preceding weeks. These 53 deaths were equal to an annual rate of 1·6 per 1000, which was 0 2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 10, 13, and 17 in the three preceding weeks, further rose last week to 22, all of which occurred in Glasgow. The deaths from diarrhœa, which had been 20 and 22 in the two preceding weeks, declined again to 12 last week, and included five in Dundee, four in Glasgow, and two in Aberdeen. The fatal cases of whooping-cough, which had been four, seven, and nine in the three preceding weeks, declined again last week to seven, of which three were registered in Glasgow and two in Edinburgh. The deaths referred to different forms of "fever," which had been ten, six, and four in the three preceding weeks, rose again to five last week and included two in Glasgow and two in Dundee. The fatal cases of diphtheria which had been four, seven, and five in the three preceding weeks, declined again last week to four, of which two were recorded in Glasgow and two in Greenock. The deaths from small-pox, which had been one, four, and three in the three preceding weeks, declined last week to two, both of which occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 129, 136, and 148 in the three preceding weeks, declined again last week to 138, but were slightly in excess of the number in the corresponding period of last year. The causes of 24, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·9, 24·5, and 24 8 per 1000 in the three preceding weeks, further rose to 27·5 per 1000 during the week ending Dec 5th. During the past four weeks the death-rate has averaged 24 4 per 1000, the rates during the same period being 17 1 in London and 16·6 in Edinburgh. The 200 deaths of persons belonging to Dublin registered during the week under notice were 20 in excess of the number in the preceding week and included 13 which were referred to the principal infectious diseases, against seven, nine, and 11 in the three preceding weeks; of these, five resulted from whooping-cough, four from "fever," two from scarlet fever, and two from diphtheria, but not any from small pox, measles, or diarrhœa. These 13 deaths were equal to an annual rate of 1·8 per 1000, the death-rates last week from the principal infectious diseases being 1·2 in London and 0 5 in Edinburgh. The fatal cases of whooping-cough, which had been three, two, and three in the three preceding weeks, further rose last week to five The deaths referred to different forms of "fever," which had been three, one, and four in the three preceding weeks, were again four last week. The 200 deaths in Dublin last week included 44 of children under one year of age and 55 of persons aged 60 years and upwards; the deat[illegible] decline from the number in the [illegible] of elderly persons were consider[illegible] from violence and three inquest cases were registered during the week and 74, or more than one-third, of the deaths occurred in public institutions. The causes of eight, or 4 per cent., of the deaths were not certified.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1903.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·0 per 1000 of the population, estimated at 4,613,812 persons in the middle of the year. In the three preceding months the rates had been 5·5, 6·5, and 6·8 per 1000 respectively. The rates were considerably below the average in Kensington, Chelsea, the City of Westminster, Hampstead, Stoke Newington, Finsbury, and Greenwich, while they showed the largest excess in St. Marylebone, Hackney, Shoreditch, Bethnal Green, Stepney, and Deptford. The prevalence of small-pox showed a slight diminution last month; of the 33 cases notified during the month eight belonged to the City of Westminster, seven to Wandsworth, four to St. Pancras, four to Islington, three to Southwark, and three to Camberwell. The Metropolitan Asylums hospitals contained 40 small-pox patients at the end of last month, against 57, 21, and 42 at the end of the three preceding months; the weekly admissions averaged eight, against nine, five, and ten in the three preceding months. Scarlet fever was considerably less prevalent during November than it had been in either of the two preceding months; the greatest proportional prevalence of this disease occurred in Paddington, Hackney, Bethnal Green, Stepney, Deptford, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1754, 1849, and 1794 at the end of the three preceding months had further declined to 1738 at the end of November; the weekly admissions averaged 184, against 211, 241, and 210 in the three preceding months. The prevalence of diphtheria showed a marked decline from that in the preceding month. Among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, St Marylebone, Bethnal Green, Poplar, Wandsworth, and Deptford. There were 763 diphtheria patients remaining under treatment in the Metropolitan Asylums hospitals at the end of last month, against 716, 671, and 753 at the end of the three preceding months. The weekly admissions averaged 109, against 94, 114, and 121 in the three preceding months. The prevalence of enteric fever, [illegible] continuously during the seven preceding [illegible]ber; the greatest [illegible]red in Hackney, [illegible]ermondsey, and Woolwich. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 172, 247, and 285 at the end of the three preceding months, had increased to 286 at the end of last month; the weekly admissions averaged 45, against 27, 40, and 44 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Holborn, Finsbury, Shoreditch, Bethnal Green, and Bermondsey. The 14 cases of puerperal fever notified last month included two in Wandsworth and two in Lewisham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Nov. 28th, the deaths of 5735 persons belonging to London were registered, equal to an annual rate of 16·2 per 1000, against 13·5, 14 4, and 14·6 per 1000 in the three preceding

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING NOVEMBER, 1903.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1903.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

* Including membranous croup.

months. The lowest death-rates in London last month were 10·5 in Lewisham, 12·4 in Hampstead, 13·4 in Hackney, 13·8 in Paddington and in Greenwich, and 13·9 in Chelsea; the highest rates were 19·2 in Southwark, 19·6 in Holborn, 20·1 in Bethnal Green, 20·8 in Bermondsey, 21·9 Shoreditch, and 22·4 in Finsbury. The 5735 deaths from all causes included 485 which were referred to the principal infectious diseases; of these, two resulted from small-pox, 119 from measles, 29 from scarlet fever, 56 from diphtheria, 49 from whooping-cough, 58 from enteric fever, and 172 from diarrhœa. The lowest death-rates last month from these infectious diseases were recorded in Hammersmith, Hampstead, St. Pancras, Islington, Stoke Newington, Holborn, and Lewisham; and the highest rates in Fulham, Finsbury, Shoreditch, Bethnal Green, Poplar, Southwark, and Wandsworth. The two fatal cases of small-pox belonged to the City of Westminster. The 119 deaths from measles were 50 below the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Fulham, the City of Westminster, Finsbury, Shoreditch, Lambeth, Battersea, and Wandsworth. The 29 deaths from scarlet fever showed a decline of 39 from the corrected average number; among the various boroughs the greatest proportional mortality from this disease occurred in Kensington, St. Pancras, the City of London, Shoreditch, Bethnal Green, and Deptford. The 56 fatal cases of diphtheria were only slightly over one quarter of the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in St. Marylebone, Poplar, Wandsworth, Deptford, Greenwich, and Lewisham. The 49 deaths from whooping-cough were 30 below the corrected average number; among the various metropolitan boroughs this disease showed the highest proportional mortality in Shoreditch, Bethnal Green, Stepney, Lambeth, Deptford, and Woolwich. The 58 deaths from enteric fever were 35 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Fulham, Chelsea, Stoke Newington, Holborn, Shoreditch, and Southwark. The 172 fatal cases of diarrhœa were 95 in excess of the corrected average number; the greatest proportional mortality from this disease occurred in Fulham, Bethnal Green, Poplar, Southwark, Camberwell, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was nearly 30 per cent. below the average.

Infant mortality in London during November, measured by the proportion of deaths among children under one year of age to registered births, was equal to 156 per 1000. The lowest rates of infant mortality were recorded in Paddington, Fulham, City of Westminster, St. Marylebone, Stoke Newington, and Lewisham; and the highest rates in Holborn, the City of London, Shoreditch, Bethnal Green, Southwark, Bermondsey, and Deptford.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets Thomas Bolster has been placed on the retired list and Deputy Inspector-General of Hospitals and Fleets John C. Birkmyre Maclean has been promoted to the rank of Inspector-General of Hospitals and Fleets.

The following appointments are notified:—Fleet Surgeons: C. W. Buchanan-Hamilton to the *Glory;* C. E. Geoghegan to the *King Alfred* for voyage home; G. Wilson to the *King Alfred* and to the *Leviathan;* S. T. O'Grady to the *Impregnable;* A. G. Andrews to Yarmouth Hospital; C. W. Sharples to the *St. Vincent;* J. O'B. Williams to the *Euryalus;* and J. Dudley to the Royal Marines, Plymouth. Surgeons: J. W. Bird to the *Excellent;* J. Whelan to the *Lion;* J. Martin and R. F. MacMahon to the *King Alfred;* A. J. Laurie to the *Cambridge;* J. Thornhill to the *Kinsha;* H. Huskinson and J. G. Wallis to the *King Alfred* for voyage home; J. E. H. Phillips and N. H. Mummery to the *Euryalus;* F. Bolster to Chatham Hospital; and F. E. Bolton to the *Resolution.*

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants to be Captains (dated Nov. 29th, 1903):—H. J. McGrigor, W. R. P. Goodwin, J. H. Brunskill, A. C. Duffey, A. W. Gibson, C. D. Myles, R. N. Hunt, H. E. J. A. Howley, R. F. M. Fawcett, W. L. Steele, H. A. Davidson, J. W. West, W. Riach, H. R. Bateman, H. G. Pinches, T. White, J. C. Kennedy, A. R. C. Parsons, J. B. Cautley, W. M. B. Sparkes, S. B. Smith, E. W. Powell, J. L. Jones (dated Nov. 30th, 1903); and E. S. Worthington.

The undermentioned Lieutenants are confirmed in that rank:—J. M. M. Crawford, C. Bramhall, T. E. Harty, H. H. Swanzy, J. E. Skey, H. T. Stack.

INDIAN MEDICAL SERVICE.

The King has approved of the resignation from the service of Captain John Elliott Robinson (dated Nov. 1st, 1903).

VOLUNTEER CORPS.

Rifle: 2nd (the Weald of Kent) Volunteer Battalion the Buffs (East Kent Regiment): *Brigade Surgeon-Lieutenant-Colonel* T. Joyce, Senior Medical Officer, Sussex and Kent Volunteer Infantry Brigade, resigns his commission and is granted the honorary rank of Surgeon-Colonel with permission to wear the prescribed uniform on retirement (dated Dec. 5th, 1903). 3rd (Dundee Highland) Volunteer Battalion the Black Watch (Royal Highlanders): Alexander Kirk Traill to be Surgeon-Lieutenant (dated Dec. 5th, 1903). 2nd Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Surgeon-Lieutenant-Colonel W. G. Lowe resigns his commission and is granted the honorary rank of Surgeon Colonel with permission to wear the prescribed uniform on retirement (dated Dec. 5th, 1903).

MENTIONED IN DESPATCHES.

The name of Lieutenant Hornabrook, medical officer of the Natal Mounted Rifles, has been added to the list of those mentioned for meritorious service in South Africa in Lord Roberts's despatch of April 2nd, 1901.

RECENT ARMY ORDERS.

Among the Army orders for December we notice the following:—*Royal Army Medical Corps: Examination of Majors for promotion.*—For the year 1904 the special subjects for the examination of majors, R.A.M.C., for promotion to lieutenant-colonel, referred to in paragraph 5 (*a*), (*b*), and (*c*), Appendix VIII B (formerly VIII A) of the King's Regulations will be: Subject 5 (*a*), Medical History of the more important campaigns; Subject 5 (*b*), A general knowledge of the Army Medical Services of other Powers. Candidates will not be examined in subject 5 (*c*), The Laws and Customs of War.

GONORRHŒA AMONG SOLDIERS.

In a clinical lecture delivered at the Val-de-Grâce School of Military Medicine and reported in the *Archives de Médecine et de Pharmacie Militaires* for October, Professor Toubert quotes some remarkable statistics regarding the prevalence of gonorrhœa at the present day and lays emphasis upon the necessity of paying the greatest attention to the treatment of the affection when it occurs in soldiers. According to Neisser blennorrhagia follows next to measles as the most widespread of all diseases. At Breslau from 15 to 30 per 1000 of the military population, and about 87 per 1000 of the students were affected; while in New York, according to Nœggerath, out of every 1000 men who get married 800 have had the complaint, no fewer than 720 of these remaining uncured at the time of their marriage. Gonorrhœa, though less dreaded than syphilis, is nevertheless a most serious disease, capable of causing disastrous results not only in the males primarily affected but also in the innocent females to whom they impart the contagion. With proper treatment the prognosis in gonorrhœa should be favourable, but unfortunately medical men, in Professor Toubert's opinion, may, generally speaking, be said to neglect the disease. They, as a rule, underrate its insidious and tenacious character, treat its symptoms more or less empirically, and do not take the trouble to assure themselves that its seeds have been thoroughly eradicated. As soon as the more prominent manifestations have disappeared or become latent they dismiss their patients, although still in a condition which cannot but render them dangerous to society. Before pronouncing a gonorrhœal subject cured the most searching verification of the fact is necessary. Rough tests alone, such as beer drinking or the well-known procedure of Guyon, are not sufficient; a thorough exploration of the urethra from one end to the other is absolutely essential, together with a systematic examination of the urine. Professor

Toubert reposes great faith in the *explorateur à boule.* In skilful hands this is a most useful instrument for the detection of localised centres of infection. Although, as Desault said, gonorrhœa may often "die of old age" still in some cases it may persist for years. Ricord met with a case of 40 years' standing and Desormeaux with one of 50 years'. The *vis medicatrix naturæ* alone will seldom effect a perfect cure. Sometimes in chronic cases a keratinised condition of the urethral mucous membrane interferes with the action of local remedies. When this takes place Professor Toubert directs the patient to retain in his urethra by mechanical means about five cubic centimetres of the following solution for a period of from one to three hours: hermophenyl, 0 75 gramme; protargol, 0·75 gramme; glycerine, 30 cubic centimetres; chlorhydrate of cocaine, one gramme; water, 1 litre. This solution may be made stronger or weaker according to circumstances. In conclusion Professor Toubert says: "From the day when gonorrhœal affections shall be treated methodically during their acute stage they will cease to become chronic. ...... For many reasons the treatment of blennorrhagia deserves more than the indifference, or it may be the disdain, which heretofore it has too often met with on the part of medical men even more than from patients."

INDIAN MEDICAL SERVICE.

The *London Gazette* of Dec. 4th contains revised regulations for the Indian Medical Service which provide that the substantive ranks of medical officers in the Indian military forces shall be as follows: surgeon general (ranking as major-general), colonel, lieutenant colonel, major, captain, and lieutenant. Subject to certain conditions, a lieutenant shall be promoted to the rank of captain on completing three years' full pay service, a captain to the rank of major on completing 12 years, and a major to the rank of lieutenant-colonel on completing 20 years. Time on half pay not exceeding one year shall be allowed to reckon as service for promotion under Articles 2, 3, and 4 where removal to half-pay has been the consequence of ill-health caused by military service. A captain, after at least six years' service, a major, or a lieutenant-colonel may be promoted to the next higher rank by brevet for distinguished service in the field or for distinguished service of an exceptional nature other than in the field. A certain number of lieutenant-colonels may be specially selected for increased pay for ability and merit. Promotion from the rank of lieutenant-colonel with increased pay to that of colonel, and from the rank of colonel to that of surgeon-general, shall be given by selection for ability and merit. A lieutenant-colonel may also be promoted to the rank of colonel and a colonel to the rank of surgeon general for distinguished service in the field. Exchanges between officers of the Indian Medical Service and officers of the Royal Army Medical Corps below the rank of major, and transfers of such officers from either of these services to the other, shall be permitted subject to the approval of the Secretary of State for War and of the Secretary of State for India in Council, and on the following conditions: (1) that the officers shall not have less than seven years' service; (2) that the senior officer exchanging shall take the place of the junior on the Departmental List and shall not be promoted under Article 3, 4, or 5 until the officer next above him shall have been so promoted; (3) that the junior officer exchanging shall be placed for seniority next below all medical officers whose commissions have the same date as his own; and that the officer transferred shall be placed for seniority below all medical officers holding the same rank at the time of his transfer and shall not be promoted under Article 3, 4, or 5 until the officer next above him shall have been promoted. With a view to maintain the efficiency of the service medical officers shall be placed on the retired list when they attain the following ages: surgeon general and colonel at 60 years and lieutenant colonel and major at 55 years.

THE JOURNAL OF THE ROYAL ARMY MEDICAL CORPS

The sixth number of this journal, so far from showing any sign of decreasing interest and usefulness, seems to be growing and developing in a satisfactory and promising way. Among the articles in the December number we may refer to an excellent paper by Lieutenant Colonel R. H. Firth on a Comparative Study of Some Dysentery Bacilli and to a very useful and instructive contribution from Lieutenant-Colonel W. G. Macpherson, C.M.G., R.A.M.C., on the German Regulations for Utilising Voluntary Aid in War. Those who are at all interested in the subject of voluntary-aid organisations will do well to read what Lieutenant-Colonel Macpherson has to say.

RECRUITING OFFICERS.

We are glad to notice a change introduced into the regulations for recruiting which we have long advocated as very desirable in the interest of the service. Instead of having army recruiting officers located in undesirable positions or hidden away in back streets, as has hitherto been the case, we read that "in hiring recruiting houses and rooms only such as are suitable in every way and situated in respectable localities will be selected."

Looking Back.

FROM

THE LANCET, *SATURDAY*, DEC. 10, 1825.

TOBACCO SMOKING.

To the Editor of THE LANCET.

SIR,—If some of your friends will answer this note, the answer will be read with interest by many individuals.

In Turkey, Spain, and Portugal, a peculiar mode of smoke ing prevails; the smoke of the pipe or segar, is quietly inhaled with the breath, and allowed to pass through the nostrils, without any effort, by the mere expiration of the breath.

Medical men in England refuse to allow that the smoke passes into the lungs, but if they were to see the method of smoking practised by Turks, &c., they would probably allow that it is actually inhaled into the lungs.

In Spain and Portugal, a thin paper, manufactured from straw, and without size, is used for making segars, by rolling up some tobacco in the paper, until the whole is about the size of a common pencil and the length of a finger.

The tobacco itself cannot get into the stomach or lungs, as in the case of snuff taking, nor can the raw juice of the tobacco do it, as in the case of quid-chewing; but the mouth, nasal passage, and (I think) the lungs, gullet, and stomach, must be powerfully coated with smoke, and whatever that smoke contains.

Turks are perpetually smoking; Spaniards and Portuguese use tobacco profusely; and since the army returned from the Peninsula, the habit has become fashionable; the increased number of tobacco shops must be evident to every observer.

Now, Sir, I should be glad to know, and I believe a great number of persons besides myself would be glad to know, what effect must be produced upon the structural and functional condition of the stomach and lungs by this habit.

I am, respectfully, Sir,
Your very obedient servant,
CIGARRO.

⁂ If "Cigarro" were alive what would he think of the prevalence of smoking? Medical men now know that genuine inhalation does take place, though probably it does not occur so often as is believed. Abuse of tobacco brings evils that have been widely recognised, but as to the pathological effects of its moderate use there is as much doubt now as there was when "Cigarro" addressed us on the subject nearly 80 years ago. This has been recently shown by correspondence in our columns.—ED. L.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—Dr. Frederick Spicer, the President, took the chair at the autumnal dinner of this association which was held at the Café Monico on Dec. 3rd. The toast list was limited to the usual loyal toasts and that of the University of Durham and they were given from the chair. Sir William Selby Church, Bart., who was recently elected an honorary member, paid the association the compliment of attending the dinner as a member.

Correspondence.

"Audi alteram partem."

THE NEED FOR FURTHER REFORMS IN THE DEPARTMENT OF ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—I have naturally enough been greatly interested in the letter of your correspondent dealing with the Relation of the Anæsthetist to the Patient and to the Surgeon, and whilst fully agreeing with the leading article in THE LANCET of Nov. 21st, p. 1442, and with the anonymous writer of the letter in the same issue as to the present unsatisfactory nature of these relations, I would submit that the reform proposed, which is in itself an excellent one, is of secondary importance as compared to other reforms which are, to my mind, more urgently needed in this department of practice. For many years past it has seemed to me that if the profession is to do itself justice, if the interests of the public are to be properly safeguarded, and if the anæsthetist is to be given his right position certain changes must be made in the very foundations of this department. The principles under which we have worked and still work have grown up side by side with, and have been dependent upon, certain conditions in the great field of surgery, but as these conditions have completely changed it is obvious that our principles should have changed also and in a corresponding degree. May I therefore be permitted to indicate some of the more pressing reforms which seem to me to be called for?

I do not deny that the position of this department has within recent years somewhat improved and that the public and profession have thereby benefited, but there is ample evidence that further reforms are necessary. The very fact that improvement is noticeable is in itself an indication that the roads along which we have been travelling have been the true roads of advance and an argument for pushing forward in the same direction. The causes which have led up to this somewhat improved state of affairs are not difficult to define. The better education of students, the inclusion of the subject of anæsthetics in the curriculum, the appointment of special anæsthetists on a more extensive scale, and, above all, the dissemination and appreciation of the proper principles of anæsthetisation, these are amongst the most important. It is also satisfactory to observe that the attitude of the profession as a whole towards this branch of practice has distinctly changed during recent years. This change is doubtless due partly to the revolutionary advances in surgery brought about by Lister's great work which have had the effect, as I shall presently show, of giving to the risk of surgical anæsthesia its true significance, partly to so much attention having been devoted to the problems of the subject by some of the ablest physiologists of our day, and partly to the recognition by the profession of the advantages that have accrued from the establishment of special departments and from the appointment of special officers for those departments. But this slightly improved position of the department and this fuller appreciation of its work should, I think, be looked upon merely as indicating the commencement of a greater development. Our ambition should be progressively to raise our standards with the object of one day providing surgery proper with a far more satisfactory department than that which at present exists. It is therefore necessary to consider our disabilities, and as the foremost amongst them is the present unnecessarily high risk of surgical anæsthesia the first reform needed must be a reduction of this risk. It is only just beginning to dawn upon the profession that this risk may by proper precautions be reduced to infinitesimal proportions, and before any attention can be seriously paid to such comparatively trifling reforms as those which have been suggested by your correspondent we must surely endeavour to introduce a reform of far greater importance—that by which the death-rate of anæsthesia will be so reduced as to become a negligible factor in surgery. All reforms must hinge upon this one.

Let me next endeavour to show how a want of parallelism between surgery proper and that branch of it which we are now considering has come about. Prior to the days of aseptic surgery, when any given surgical operation had its not inconsiderable risk, little was thought of any possible danger from the anæsthetic. The major shadow—the risk of the operation—included and altogether obscured the minor shadow—the risk of the anæsthetic. But improved surgical methods have changed all this, and putting on one side desperate and unfavourable cases the risk to life of a surgical procedure of to day is, *quâ* that procedure, so small that the scrupulously careful surgeon hardly takes it into consideration. In other words, the fading of the major shadow has brought into prominence the true proportions of the minor and we find ourselves to-day face to face with a disproportion in risk which, whilst it may be creditable to the average operating surgeon, is distinctly discreditable to the average anæsthetist The enemy has come out into the open and we find that he is more formidable than was supposed. Had surgeons remained satisfied with the comparatively light form of unconsciousness provided for them 30 or 40 years ago this risk of anæsthesia would certainly be less than it is at present. The demands of surgery, however, so far as the depth of anæsthesia is concerned, are far greater than they were formerly and it hence happens that in a considerable proportion of cases that now come to the operating table—cases, for example, in which the patient is termed a "bad subject" whilst the operation is a simple one—the responsibilities of the anæsthetist are as great as those of the surgeon. Moreover, it often happens that this deep form of anæsthesia has to be maintained for protracted periods, so that the resources of the anæsthetist may be taxed to an even greater degree than those of his colleague.

What is the present state of things in actual practice? In hospital we find that the [illegible] operations is constantly [illegible] existing arrangements for [illegible] is, however, little or no [illegible] At some hospitals the [illegible] administered by officially appointed anæsthetists who are as a rule non-resident. At other institutions the great bulk of the anæsthetics are given by clinical assistants, house surgeons, or students, the surgeons holding themselves more or less responsible for the safety of their patients. If, as is generally the case, the anæsthetists are non-resident some of the most difficult cases for anæsthesia—cases such as the visiting anæsthetist may never see for the simple reason that they are cases of urgency—are placed in the hands of comparatively inexperienced house officers. Then again a large number of minor operations are annually performed at most hospitals by house surgeons who may be unable to obtain anything approaching skilled assistants as regards the anæsthetic. It is in this way that so many accidents occur during comparatively trivial operations. In some hospitals certain resident or non-resident officers act vicariously as anæsthetists, a plan which is open to the serious objection that such officers may have no special aptitude for administering anæsthetics, whilst they may be interested in the surgical aspects of the case and so be tempted to pay more attention to the operation than to the anæsthetic. Where there is much pressure of work considerable risk may be incurrred by the anæsthetist having insufficient time carefully to examine his patients beforehand, to cleanse or to sterilise his apparatus, and to attend to the numerous details which collectively constitute success. In private practice the state of things is, at all events from the surgeon's point of view, often equally unsatisfactory, for [illegible] of cases the medical practitioner wishes to [illegible] practice [illegible] of the [illegible] day and difficulties arise which in a not inconsiderable proportion of cases actually militate against the success of the operation. Much of the discredit which attaches to anæsthesia has originated in this way.

Now what is the result of this unsatisfactory state of things? It may be described as a threefold result. In the first place, the public, as represented by the patients who are subjected to the unskilled anæsthetisation incidental to the present systems, are unnecessarily inconvenienced and alarmed. In the second place, the success of operations is greatly interfered with. In the third place, human life is unnecessarily sacrificed. One is always meeting with patients who give one the most weird accounts of what befel them at the dentists, how they smashed the furniture, assaulted the rubella, is likely still further to confuse diagnosis. If, however, Dr. Biss's object is to emphasise the difficulties of diagnosis then I sincerely hope that his paper will have the desired effect and that it will lead to the exercise of more care on this point, though it is no less sad than remarkable that at this time of day it should be thought necessary to write at such length to demonstrate that membrane is not essential to diphtheria, that the rash may be wanting in scarlet fever, and that the diagnosis of some forms of sore-throat is difficult—facts which were known and taught years ago by Graves and Trousseau.[1]

Dr. Dukes in his criticism of Dr. Biss's paper makes a statement which shows how widely different may be the experiences of two medical practitioners, the one resident in Rugby, whose personal knowledge of infectious disease has, I understand (Dr. Dukes will correct me if I am wrong), mostly been acquired from an attendance upon a large school of boys belonging to the better classes of society; the other resident for some years in a fever hospital whose patients come from the crowded East of London. The statement I refer to is that in the position he holds it is so infinitely rare for these diseases to occur as single cases. Just so, in the position he holds. But in London the occurrence of single cases, whether masked or patent, is of anything but infinite rarity. Infinite rarity is for all practical purposes the equivalent of total absence, so that Dr. Dukes has to all intents and purposes to wait never more than a few days before his doubts as to the nature of the disease are set at rest. Would that I were as fortunate as he in finding so simple a solution of my difficulties!

Dr. Dukes more than once makes use of the statement that these diseases breed true. I am not quite sure exactly what is meant by this expression. I think different writers use it in different senses. If by breeding true Dr. Dukes means that if an unequivocal case of a given infectious disease (say scarlet fever) gives rise to another unequivocal case then the second case will also be one of the same nature (scarlet fever and not measles, &c.), then I am at one with him. But if he insists that an uneqivocal case of scarlet fever necessarily gives rise to an unequivocal case of scarlet fever then I demur; for the unequivocal case may give rise to the equivocal and (as Dr. Dukes himself admits) the equivocal to the unequivocal; and lastly, a fact which Dr. Dukes's experience of the infinite rarity of single cases has apparently led him to overlook, a case, whether equivocal or unequivocal, may never breed at all.

Laying hold of a somewhat loose expression in Dr. Biss's paper Dr. Dukes seizes the opportunity of making an attack on the administration of fever hospitals which I am surprised to find coming from him. The question of the value and influence of fever hospitals is one that will not be profitably discussed unless it is discussed with fairness. Doubtless the question of administration is involved in the wider question. But I think that before Dr. Dukes wrote what he has written about the want of observation and quarantine rooms in fever hospitals and descended to the use of such phrases as "setting their house in order" and "saving these hospitals from themselves" he might have taken the trouble to find out what has been done and is being done with respect to details of administration, not only by lay committees of management but also by certain members of his own profession who occupy positions to the responsibilities of which they are quite alive.—I am, Sirs, yours faithfully,

Homerton, N.E., Dec. 2nd, 1903. E. W. GOODALL

To the Editors of THE LANCET.

SIRS,—I should, indeed, be neglectful of the amenities of debate did I fail to express my appreciation of Dr. Clement Dukes's graceful compliment to myself before seeking to reply to his criticisms on my paper on the Borderlands of Diphtheria and Scarlet Fever. The pleasure I feel at his kind words is the keener in that they come from so illustrious a worker in the same field as myself. But I must not allow my sense of Dr. Clement Dukes's courtesy to blind me to the fact that he traverses my whole argument, in so far at least as he interprets it in the sense I intended. My contention briefly was this. That the study of these diseases brings into relief a general principle of medicine—namely, that diseases are only conventional names for certain departures from health; that as all departures from health are merely changes of state there can be no hard-and-fast line between any diseases; that by taking a little group of closely allied diseases one can advantageously trace the transition-steps between them; that this study is best pursued by regarding those cases of sickness that do not bear the text-book features of any single disease; and, finally, that due attention to these considerations will show that the art of diagnosis—that is to say, skill in assigning cases of sickness to definite groups—is limited because it cannot assign sicknesses to groups that do not exist. To these propositions Dr. Clement Dukes replies: 1. That diseases never lose their identity; though they may vary in type they always breed true. 2. That cases are not borderland cases when they infect others. 3. That the poisons which generate infectious diseases are "absolute entities." 4. That fever hospitals are very bad places because borderland cases (which are not borderland cases) cannot be isolated from each other in them.

Let me deal briefly with these *seriatim:* 1. This is, of course, the conception of disease at which my shaft was levelled. It seems to me a cramped and artificial one. It presupposes that disease is an entity in itself, something foreign and external which is superimposed on a patient, and not, as I should regard it, merely a concatenation of morbid changes in sick people. Two persons are ailing with the same symptoms. We say they have the same disease, but we mean that in them there are similar perturbations in similar tissues. But one may have some perturbations that the other has not. Let us say that of two patients with sore throats one has an erythematous rash of the skin, whilst the other has not. Are they still suffering from the same disease? It is a question of degree. The decision we come to, the diagnosis we make, depends upon the weight we individually or collectively attach to particular phenomena or groups of phenomena. It may seem advantageous to assign one case to this "disease," another to that, or they may be regarded as variations of the same "disease." At a certain point the links may be equally strong with two "diseases." In that case the disease is undiagnosable. If we hold this view, what becomes of the expression "breeding true"? I confess that to me the phrase smacks more of the empiricism of the dog-fancier's yard than of the exactitude of scientific ideas. Is it, moreover, not somewhat of a shibboleth? Does not variation constitute the basis of the breeder's art? Are not deviations from the "truth" the potent element in all development or degeneration of species? Identity becomes lost after a number of variations have been passed through. Is the gorgeous double dahlia of to-day the same as the modest bloom that Dahl brought to Europe three centuries ago? or, to put a stronger case, is a bird a reptile? 2. This contention of Dr. Clement Dukes's is more rhetorical than real. A case may be far from the mean of one disease and near the border of another disease and yet serve as a source of infection to others of one or even both these diseases. 3. I fear I cannot reply to this contention, as it is so vaguely expressed that it is difficult to attach an exact meaning to the phrase. What are the "poisons"? and what does "generate" mean in this connexion? I fear that my spectacles are not sufficiently polychromatic. 4. I was not concerned with the defence of our isolation hospital system. It has many faults and many disabilities, of which no one is more conscious than I. My practical point was to show how far some of these disabilities reached. If Dr. Clement Dukes will support Dr. C. Killick Millard's proposal for inquiry into this question he will have my cordial coöperation.

I am, Sirs, yours faithfully,

Eastbourne, Dec. 2nd, 1903. HUBERT E. J. BISS.

HETEROGENESIS.

To the Editors of THE LANCET.

SIRS,—I unfortunately overlooked the letter of Dr. J. M. Fortescue-Brickdale in THE LANCET of Nov. 21st, p. 1459, which has only this day been brought to my notice. It contains some rather serious misrepresentations of my views and statements which ought not to pass uncorrected.

In the last paragraph of his letter the writer distinctly intimates that I "ignore entirely the results of the direct injection of tubercle bacilli in pure cultures into animals." This suggestion is absolutely devoid of all foundation. I freely admit that tubercle bacilli may and do act as veritable contagia in the spread of the disease alike in the lower animals and in man and I am surprised that anyone should suppose I think otherwise. This erroneous suggestion must, I suppose, have owed its origin to my expressed belief that the disease is sometimes generable apart from contagion, coupled with the widely spread notion that a contagious disease cannot arise *de novo*, the latter being a conclusion which to many seems to have been made certain by the discovery that micro-organisms constitute the contagia of so many of the communicable diseases.

---

[1] Sanné's remarks on "Diphthérie sans Diphthérie," alluded to by Dr. Biss, are almost word for word those used by Trousseau at the commencement of his lecture on "Common Membranous Sore-throat."

Granting the facts of contagion, let us look for a moment at the possible modes of origin of a contagious disease. One or other of three views may be held concerning the origin of the contagium. We may, to put it briefly, believe (1) in special creation; (2) in transmutation; and (3) in its *de novo* origin.

1. We have in the first place the notion that the various contagia have been specially *created* with a view to the production of this or that disease. This surely cannot be regarded as a scientific hypothesis. It is a teleological conception entirely out of harmony with existing beliefs. And if it is to be rejected a *de novo* origin, either in present or in past times, by one or other of the two remaining modes of origin is alone open for our acceptance. It is well that this should be fully realised.

2. The second view implies that there is no absolute demarcation between non-pathogenic and pathogenic organisms, and in its favour there is an immense amount of evidence showing the mutability, both in form and in function, of the micro-organisms in question. Some who do not adequately appreciate the weight of this evidence are, as a distinguished physician has lately said, willing to subscribe to the view that "the origin of the germs of disease was probably in the remote geological past," even though as to all the conditions of such occurrences they must be absolutely devoid of all knowledge. This is a nebulous and unsubstantiated point of view which does not appeal to me. I prefer to seek for actual evidence of the occurrence of such transformations in the present day, and for this reason, in your issue of Oct. 31st, p. 1220, I called attention to the conditions of origin of two experimentally produced forms of septicæmia and contended that a fair and impartial consideration of the evidence (apart from unproved assumptions) should lead to the belief that both "Davaine's septicæmia" and "Pasteur's septicæmia" had been produced over and over again *de novo*, and that the micro-organisms by which they are characterised (if not arising independently) must in such cases have been produced by the transformation of common organisms. In the case of "Davaine's septicæmia" the disease has been caused by the injection of two or three drops of putrid blood taken from a previously healthy animal. Such blood soon swarms with organisms of different kinds The deadly specific germ could not have been contained in the healthy animal from which the blood was taken, and the specific bacillus ultimately produced in the putrefying blood is said never to have been recognised in the outside world apart from such blood. To assume, nevertheless, that this specific germ is omnipresent in the atmosphere and ever ready to drop into the blood with which experiment is about to be made seems to me an absurdly gratuitous and unfounded supposition. All the evidence points rather to the conclusion that the specific bacillus has been produced from one of the common forms at some particular stage in the putrefactive process. Again, in regard to "Pasteur's septicæmia," the fact that this disease can be produced in a previously healthy animal within 24 hours by the injection of a germ-free chemical irritant into its peritoneal cavity cannot, I think, be satisfactorily explained by supposing that the organism which is the cause of the disease is always present in the intestine, and that the setting up of an intense inflammation in the peritoneum leads it to multiply rapidly and at once to begin to make its way through all the coats of the intestine in order to get into the peritoneal fluids. *These are assumptions devoid of proof, and if Dr.* Fortescue-Brickdale is disposed to give them credence it seems a pity he should not have recollected that some of the same germ-free chemical irritant introduced into the subcutaneous tissue of the healthy animal under conditions, as Sir J. Burdon Sanderson said "[illegible] of the introduction of any [illegible] will nevertheless give rise t[illegible] Do the organisms which characterise it exist also in the subcutaneous tissues of healthy animals or does he suppose them to be so abundant in the air that they are always ready to baffle the most skilful experimenter whenever an opening is once made in the skin, however minute this may be? It is, moreover, an absolute error for Dr. Fortescue-Brickdale to say that I regard the bacilli characterising Davaine's and Pasteur's septicæmia respectively as "altered forms of the same organism." No such view has been put forward by me. He is further wrong in supposing that I relied upon these experimental researches as furnishing a proof of the *de novo* origin of bacilli. I cited them rather as affording very strong evidence in favour of the transmutation hypothesis and as showing that some contagious diseases do arise *de novo*.

3 When I said in reference to micro-organisms I "have proved the possibility of their *de novo* origin" I was referring to the researches the results of which are recorded in the *Annals and Magazine of Natural History* for October last and to which reference was made in THE LANCET of Nov. 7th, p. 1316. I venture to think that the evidence there recorded, which will also be found in Section xxiii. of my "Studies in Heterogenesis" (to be published next week) is not capable of being explained in accordance with existing knowledge and commonly received views. The only legitimate interpretation of my observations and experiments, as I believe, is that bacteria and their allies can, and do, now arise by heterogenesis and the proof of this possibility I regard as of great importance for the science of medicine.

I am, Sirs, yours faithfully,

Manchester square, Dec. 4th, 1903. H. CHARLTON BASTIAN.

THE ALIEN IMMIGRANT.

To the Editors of THE LANCET.

SIRS,—I trust you will kindly give me an opportunity of replying in your columns to Mr. Morris Streimer's letter of Nov. 10th[1] and of thanking you at the same time for the very valuable criticism of my book which appeared in THE LANCET of Nov. 7th (p. 1304) and which Mr. Streimer is pleased to describe as "partial." I have been absent in Paris or should have addressed you on the subject before

Mr. Streimer objects to the assertion that the Jews are "a race apart" and says: "All experience and all study show that once social and legal restrictions are removed the people of any country tend to become homogeneous in their general characteristics." He ignores the fact that it is contrary to the precepts of the Hebrew faith that Israelites should intermarry with Gentiles and that therefore in their case no appreciable absorption among the surrounding populace takes place. They have kept themselves "a race apart" since, as before, their dispersion and are as much so in the United States to-day as anywhere else. I think that any impartial observer must admit that the national spirit among the Jews is increasing rather than diminishing. The great Zionist movement is based upon the national idea and though no trustworthy figures are available it is probable that several millions of Jews are Zionists. Why should Mr. Streimer take exception to the statement that the Jews are a race apart? For myself I can see nothing derogatory in it. Mr. Streimer ridicules my assertion that there are streets in the East-end where "it is an exception to hear the English language spoken." He ignores the official testimony, to which I refer, of Chief Superintendent Mulvaney of the "H" Division who told the Royal Commission on Alien Immigration that in six years 107 streets in Stepney alone had passed *wholly* into the occupation of aliens. It is not probable that the new inhabitants speak English.

I agree with Mr Streimer when he lays stress on the question of sanitation. I notice that as recently as Nov. 23rd the medical officer of health of Stepney reported a case of small-pox—that of a Russian whose illness was notified two days after his arrival in England. And I observe that Mr. Cluer at Worship street Police-court on Nov. 18th made the following remarks about some of our East-end immigrants. "You come into this country to make a living, defying or breaking our laws, crowding your dirt and indecency together, and bring your family after you." It is not, in my opinion, the case that "the question of our foreign population is but one aspect of the general social question." The question is whether we wish to have our own social ills aggravated by the constant arrival of aliens of this class who come here in consequence of no natural operation of the law of supply and demand but on account of governmental measures of extrusion adopted in Eastern Europe.

THE URBAN HOSPITAL TREATMENT OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—The report on the urban hospital treatment of tuberculosis by the committee appointed by the Society for the Study of Disease in Children to inquire into the matter and report to them is still under consideration by that body, and its publication in THE LANCET of Dec. 5th, p. 1590, was owing to an unfortunate oversight. As this report is still *sub judice* its discussion at the present moment would be premature.—I am, Sirs, yours faithfully,

GEORGE CARPENTER,
Senior Honorary Secretary.
Welbeck-street, Cavendish square, W., Dec. 7th, 1903.

THE MORTALITY AFTER OPERATIONS FOR STRANGULATED UMBILICAL HERNIA.

To the Editors of THE LANCET.

SIRS,—I shall be glad if any of your readers can give me a reference to any statistics with regard to this subject. I have been unable to find any definite information but that it is unexpectedly high I believe.

I am, Sirs, yours faithfully,
Hove, Dec. 3rd, 1903. ARTHUR H. BUCK.

THE PHOSPHATES AND UREA OF URINE.

To the Editors of THE LANCET.

SIRS,—I shall be obliged if you will give me space for a somewhat belated acknowledgment of the communications from Dr. H. Harper, Dr. A. W. Gilchrist, and others, in THE LANCET of the latter end of 1902, and January of this year, referring to a paper of mine on the above subject.[1] These letters appeared at a period when serious illness prevented me from attending to anything, and I have only recently found an opportunity of looking through the back numbers of your journal.

To remove misconception (for I think there was some, partly owing perhaps to the results of the analyses having been tabulated, for the sake of brevity, so that the figures yielded by very different pathological samples were in juxtaposition), I should like to state, chiefly in reply to Dr. Gilchrist:—1. That I never thought to "establish an analogy" between the diseases. In one not a medical man I should think this presumptuous 2. As a scientific chemist I have long known the desirability that analyses of urine should represent the collective fluid excreted during 24 hours. But for the analyst, and, if I mistake not, for the medical man also, this is very often impracticable. The former, at all events, has to work with just what is submitted to him, frequently by the medical adviser, who cannot help himself. 3. Professing to no knowledge of medicine, I certainly did not intend it to appear as if I had had the temerity to make any precise comparison of the composition of tuberculous urine with that of the fluid from glycosuria or with other samples of urine from similar cases. No data were at my command for this sort of comparison, which was left, of course, to medical men. I sent these analyses, such as they were, to THE LANCET on the chance that they might be of some service or interest to my medical brethren; but I was far from wishing to seem to attach to them undue importance and was particular in giving what information I possessed, as to times, &c, so as to show clearly that the samples were not representative of the entire 24 hours' excretion. Any remarks—they could hardly be called conclusions—were extremely guarded, and confined to comparisons of the most general kind, not with analyses of other pathological urines, but with such statements regarding the limits of composition of *normal* urine as are to be found in ordinary works of reference—by Halliburton, Hammarsten, Allen, Pearmain and Moor, and others; and referred only to the actual samples, *as they were received.* I do not at all claim infallibility for the remarks in question. At the worst, if the paper had no other use, the figures recorded such analytical results as may be yielded in particular circumstances and by limited samples, representing only part of the 24 hours—such as medical practitioners must often be forced to be content with. 4. As far as my own imperfect opportunities permitted me to judge, I was under the impression that there were not very many readily accessible analyses, at all events as full as that of the tuberculous sample, and personally I had never seen any published analysis of urine from a case of *tubercle of the bladder.* For my own information, I should be grateful for references to such analyses, and interested to know whether the figures are similar to, or different from, those yielded in *other* cases of tuberculosis, as of the lungs; also whether the "graph" in Dr. Gilchrist's communication represented the results from one sample of tuberculous urine or the mean of several.

Lastly, the cautiously chosen title of the paper, "Observed Variations," &c., was changed in the later communications to "The Low Phosphates and Urea," &c. I must disclaim responsibility for this. My own use (in the paper) of the expression, "low phosphates" related solely to the particular set of analyses and to the actual specimens of urine received, imperfectly representative as they may have been. This was without any universal application or generalisation, such as the latter title might imply: I intended none.—I am, Sirs, yours faithfully,

EDWY G CLAYTON, F.I.C., F.C.S.
Holborn Viaduct, E.C., Nov. 30th, 1903.

RADIUM AND THE BACILLUS TYPHOSUS.

To the Editors of THE LANCET.

SIRS,—The following experiences with bromide of radium upon cultures of the bacillus typhosus may be of interest to some of your readers. The cultures were of the usual kind, in agar, and were exposed to the rays of 50 milligrammes of the salt for periods varying from 15 minutes to 48 hours. The longer exposures were in the dark in order to eliminate any inhibitory effect of daylight upon the cultures. The tubes containing the cultures were at first placed horizontally above the radium at a distance of five centimetres but were afterwards allowed to rest in an upright position actually upon the mica cover of the box containing the radium, so that the culture received the full rays diverging from below upwards throughout its length. From each tube subcultures were afterwards taken without difficulty and so far as could be observed there seemed to be no inhibitory action upon the growth of the culture. Rather the contrary, for, in the opinion of more than one observer, examining the cultures under a high power, there seemed to be more activity in those cultures which had been subjected to the longer exposures, and in cultures which had been exposed, than in others of the same date which had not been exposed to the radium but had been simply excluded from daylight.

These experiences would seem to lead one in the direction of supposing the beneficial action of radium in certain cases to be that of stimulation of normal tissue rather than directly bactericidal. It is not easy to determine accurately the activity of a radium salt, but at a rough estimate the radium used in this instance is sufficiently strong to make its rays apparent upon the screen through a thickness of 15 coins, half-crowns and pennies. They pass easily therefore through the thickest part of a Cabaud gauge and in therapeutic use an application to the skin of five minutes produces redness and one of ten minutes a slight burn, appearing after two days. The cultures were kindly prepared for me in the laboratory of the Westminster Hospital.

I am, Sirs, yours faithfully,
Beaumont-street, W., Dec. 5th, 1903. R. BROWNE-CARTHEW.

ST. JOHN'S HOUSE OF REST, MENTONE.

To the Editors of THE LANCET.

SIRS,—We are anxious through the medium of your journal to draw the attention of the members of the medical profession to the existence in Mentone of St. John's House of Rest which we believe to be little known to them. The institution, which was founded 25 years ago, is intended for

---

[1] THE LANCET, Sept. 6th, 1902, p. 656.

professional men who in consequence of illness or over work require rest and a mild climate and who could not otherwise afford the expense of a sojourn on the Riviera. Medical men have occasionally been among the inmates The house
a separate
dining, an
the garden *for open air treatment Applications for admission* have hitherto been few so that the house has seldom been filled except for short periods It is open from Nov 1st to May 1st The charge made is £1 a week including medical attendance We think that medical practitioners must frequently meet with cases for which such a home would prove a great boon The gentlemen who have resided in the House of Rest have expressed themselves grateful for the care and comfort which they have met with Of course, such an institution cannot be self supporting and the sum of £250 is required yearly to meet all the extra cost entailed We remain, Sirs, yours faithfully,

Obituary.

PROFESSOR PROUST.

THE Paris Faculty of Medicine has recently received a severe blow by the very sudden and unforeseen death of Professor Proust. While he was presiding over the delivery of a thesis by one of his pupils on Nov *24th* he was suddenly struck down by a paralytic seizure and although he was at once removed to his home he grew rapidly worse and died on the 26th He was born at Illiers in the department of Eure et Loire on March 18th, 1834 He determined to study medicine and had a brilliant career as a student, so that while an *interne* at the hospitals he took his doctor s degree in 1862 at the age of 28 years In 1866 he was elected agrégé and soon afterwards physician to the hospitals In 1879 he was elected a member of the Academy of Medicine in succession to Tardieu, and finally, in 1885, he was elected to the chair of hygiene in the faculty of medicine, having acted as deputy for Bouchardat for two years previously Long before this date, however, his attention had been turned towards the study of hygiene and as far back as 1869 he had been intrusted with an important mission to Russia and Persia for the purpose of studying the best means of fighting against an invasion of cholera. He was next elected a member of the Consultative Committee of Hygiene of France, to which body he acted as secretary, and Fauvel nominated him as his collaborator On Fauvel's death Professor Proust succeeded him as inspector general of the sanitary service In every question which he had to consider Professor Proust distinguished himself by the essentially practical qualities of his talents, and he had besides an infinite capacity for work, so that wherever his duties as inspector called him, whether abroad or at home, he never spared himself when any risks were to be run He was Commander of the Legion of Honour

PROFESSOR PROUST
Inspector General of the French Sanitary Service

JOHN HENRY SYLVESTER,

DEPUTY SURGEON GENERAL, I M S

WE regret to announce the death of Surgeon General Sylvester, which occurred at his residence, 16, Melbury-road, Kensington, London, W, on Nov 29th in his seventy-fourth year He began his medical studies at King's College, of which he was an associate, and for a time assisted the late Professor Owen In 1854 he went to India in the employ of the India Office and served with the 14th Light Dragoons in Persia During the Indian Mutiny he was with his regiment in the Deccan Malwa, Nerbudda, Central India and was also engaged with the Central India Field Forces and with the 1st Regiment of Beatson's Horse in Bundelkhand and Rajputana In the Umbeylla *Campaign he served as field surgeon For his services in* Persia, Umbeylla and Central India he received the medals and clasps granted for those operations At Ahmadnuggar he saw some further service and afterwards became professor in the Grant Medical College at Bombay and assistant surgeon in the *Jamsetjee Jeejeebhoy Hospital He also* served for four years on the frontier of India at Peshawur and other places On his return to Bombay he was appointed ophthalmic surgeon then professor of physiology and second physician at the Jamsetjee Jeejeebhoy Hospital He remained in India until 1875 when he retired with the rank of deputy surgeon general After his retirement he diligently devoted himself to the study of painting in London, Paris, and Italy, and for the rest of his life that art was a great source of pleasure to him His best known pictures are a portrait of the present Bishop of Peterborough, which now belongs to the Kensington Vestry and hangs in the board room of the town hall and a portrait of Field Marshal Lord Roberts which he presented to the East India United Service Club, and of which *engravings* were published by Mr Thomas McLean of the Haymarket Surgeon General Sylvester possessed great warmth of friendship and his memory will be associated with the kindest recollections Until eighteen months ago he enjoyed remarkably good health, leading a very regular and active life his hobbies, in addition to painting, being bicycling, which he practised daily up to the time of his illness and fishing *He leaves a widow and one daughter,* Mrs Hodder the wife of Major Hodder, R E

EXTENSION OF THE METROPOLITAN ASYLUMS BOARD S AMBULANCE SERVICE —The Metropolitan Asylums Board at its meeting on Nov 28th decided to extend the operations of its ambulance service so as to include the transport of medical, surgical, and mental cases for which application might from time to time be made by any authority or person within the metropolis Such extension *shall* not be held to include the removal of cases of street accident or of patients to and from the several lunatic asylums under the control of the London County Council, unless by special sanction of the ambulance committee or, on emergency, of the chairman of that council or the clerk to the board It was also decided that upon the necessary legal authority being obtained for the managers from the Local Government Board the work should be immediately undertaken and a charge of *7s 6d* made in respect of each removal, and in addition a mileage of *1s 6d* beyond the boundary of the metropolis

THE INTERNATIONAL SANITARY CONFERENCE AND THE PROPOSED PERMANENT INTERNATIONAL SANITARY BUREAU.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Paris, Dec. 7th.

IT was on Dec. 3rd and not, as previously anticipated, on Nov. 30th that the International Sanitary Convention was signed. The representatives of the various Governments having broken the continuity of their work and returned to their respective countries it was not so easy to reassemble them, particularly as there was a heavy fall of snow and the roads were blocked in more than one direction. Then after all they had only to be present as a matter of form to sign the document and to exchange mutual compliments. The real work had already been accomplished, for the Conference held its inaugural meeting as far back as Oct 10th last. Altogether there were held seven full sittings. But apart from these it was subdivided into three commissions and these latter met 35 times, so it will be seen that there was a great deal of work done. The convention drawn up as the result of all these deliberations is divided into ten chapters or "titres," to use the official French term, and these are subdivided into 184 articles. The representatives of the following 20 Powers were authorised to sign the convention. The order in which they are placed corresponds with the French alphabetical arrangement: Germany, Austro-Hungary, Belgium, Brazil, Spain, United States of America, France, Great Britain, Greece, Italy, Luxembourg, Montenegro, Holland, Persia, Portugal, Roumania, Russia, Servia, Switzerland, and Egypt. The representatives of the Argentine Republic, Denmark, Sweden, Norway, and Turkey withheld their signatures as they had not yet received the approval of their respective Governments. In spite, however, of these abstentions the Act already bears eight more signatures than the preceding conventions.

It would not be possible in a limited space to give a full account of this lengthy international agreement, nor is this in any wise necessary. The greater part of the convention merely codifies and repeats what had already been agreed upon at previous conventions. Thus the first chapter deals with the general dispositions and describes how the signatory powers are to notify to each other when any cases of cholera or plague occur on their respective territories. Then as before in the part that relates to the precautions to be taken, ships are again divided into three categories: (1) those that are infected; (2) those that are "suspect"; and (3) those that have a clean bill of health. But the great point gained, the new rule introduced, is that the delay imposed upon infected ships is reduced from 12 to seven days. Then again full cognisance is now taken of the discoveries made in regard to the action of rats in spreading plague. So important, indeed, is the destruction of rats considered that this has given rise to the creation of a new word. Therefore, and in common parlance, we are now told that the "deratisation" of ships has become obligatory. A ship is not to be considered as disinfected if there are still any rats living on board.

Then the convention contains a great deal that is applicable to certain localities such as the Red Sea, the Suez Canal, and the Persian Gulf, and there is a whole chapter on the pilgrimages to Mecca and the penalties to be inflicted on the captains of ships transporting these pilgrims who fail to carry out the sanitary regulations. Another chapter is devoted to the international sanitary councils of Constantinople, of Alexandria, and of Tangiers. It was also decided that all the signatory Governments should make representations to the Government of the Sublime Porte so that it should accept the sanitary measures proposed, for without the help of Turkey it will be difficult efficiently to protect the other countries. Yellow fever in the light of recent discoveries in regard to the action of mosquitoes was likewise discussed and, lastly, there arose the question of establishing a permanent international sanitary bureau in Paris. This final proposal is altogether a new departure and it is therefore necessary to give its history in detail. The suggestion was first made at Brussels during the opening ceremony of the Eleventh International Congress of Hygiene and Demography. The representative of the French Government, M. Henri Monod, director of the Sanitary Department at the Ministry of the Interior, on that occasion concluded his speech by saying:—

> There is another form of agreement for which I long most ardently and which I am convinced w[illegible] An agreement is established [illegible] to oppose and check the ir[illegible] sceptics are obliged to render homage to the results this has brought about. Why should we not take into consideration, why should we not prepare an agreement, an understanding for common action against endemic and preventable diseases? These latter, if we consider a more lengthy period of time, are far more destructive than the plague, the yellow fever, or the cholera. Why should there not exist one of these days an official international bureau of public hygiene to which all nations would contribute useful information and from which all nations would borrow the elements that contribute to sanitary progress? At this the fiftieth year since the first Congress of Hygiene met it is permissible to dream this dream and to foresee the formation of an international alliance for a common struggle against disease and death which should be, and which one day will be, our only enemies.

These words were greeted with loud applause and in the sections and at the general meeting held for the closure of the congress more than one motion was carried supporting the principle of an international understanding concerning legislature with regard to public health. In the Fourth Section, which dealt with industrial hygiene and where the fear of foreign competition was so often brought forward as a reason for not legislating against unwholesome industries, the President told us that he hoped the Belgian and French Governments would take the initiative to invite representatives of all nations to compare their factory and similar legislation. Then a permanent international office might be formed to help in the unification of such laws, so that the fear of foreign competition should not check the endeavours that were made to save human life. In the section that dealt with the spread of tuberculosis it was strongly felt that the dominating factors were poverty, overcrowding, and over-pressure. Such great evils can scarcely be modified in a large and general sense unless with the aid of legislative enactments. But it will always be easier for a nation to act in this sense if its commercial rivals are also taking similar steps. In this manner, and for many and various motives, the desire to establish something like a permanent international connecting link was very widely manifested. Thus, all that occurred during the Congress tended to confirm the applause that had greeted the suggestion which M. Monod threw out at the opening ceremony.

On his return to Paris M. Monod found that his immediate superior, the Minister of the Interior, had so thoroughly approved what was said in regard to an international bureau that he had submitted the whole question to the Minister of Foreign Affairs. This occurred in the middle of September. On Oct. 10th the International Sanitary Conference met in Paris under the presidency of M. Camille Barrère, French Ambassador at Rome. Nothing more had been said to M. Monod about his speech at Brussels, but after M. Barrère had welcomed the foreign representatives and described at some length the work that was set before them he added these words:—

> Now I reach the last point and its examination will not be one of the least important among the subjects that will occupy the conference A desire was expressed at the last International Congress of Hygiene by M. Monod that a sanitary office should be created which should be intrusted with the task of centralising information and of exercising a general surveillance over the application of such measures as have been prescribed. This wish, gentlemen, will be reproduced here. A few years ago this appeared premature; the moment now seems to us to have arrived to take in hand its realisation. Perhaps I may be allowed to state, for I have had some experience of international institutions which are at work and are prosperous, that I do not know of any international organisation for which there is *to day a more evident and imperative necessity*.

The representative of Italy—and it was from Italy that the request for the meeting of the conference emanated—supported M. Barrère. Commandant Santoliquido, who was the chief of the Italian delegation and vice-president of the conference, said:—

> I shall be allowed here to recall an initiative that will assuredly prove fruitful taken by M. Henri Monod on the occasion of the recent International Congress of Hygiene and Demography held at Brussels M. Henri Monod proposed, and his proposal was gladly accepted by several official delegates, that an international bureau of hygiene should be created for the common defence of the various States against the reciprocal importation of in[illegible] maladies. Could not such an [illegible]itable organisation, or rather this s[illegible]s—be observatory of the developmer[illegible]ague, commissioned to order, when [illegible], and special measures of defence i[illegible]n to could such a bureau not also [illegible] which such measures should be applied?

The object, the speaker went on to explain, was to render homogeneous the measures taken while at the same time respecting, and avoiding all interference with, the internal policy of the nations concerned and, above all, shunning any contact with politics. Commandant Santoliquido concluded by saying that—

> In any case it is evident that this international bureau, always informed in a very precise manner of all that is happening throughout the world which relates to infectious diseases, would be better able than anyone else to judge wisely what was the real magnitude of the danger and to apportion thereunto measures of defence which would thus spare the countries exposed all economical injury that was not absolutely rendered necessary by the exigencies of our common security. This bureau would also when the necessity arose be equally able to render evident the defects or negligences that may eventually occur in regard to local preventive measures and suggest what [illegible] it such a bureau existed [illegible] ect their individual or [illegible] have already said, the [illegible]

The proposal to constitute an international sanitary office and bureau was supported by all the representatives except those of Great Britain, Germany, and Austro-Hungary. When actually voting on the question, the representatives of five other nationalities, while agreeing with the proposal, desired to refer the matter to their respective Governments. The article instituting the international bureau was carried and it was further decided that it should be established in Paris. M. Monod thought that Brussels would be selected but the Italian representatives proposed, and the Russians seconded, that the town selected should be Paris and this was carried. Nevertheless it is to be clearly understood that the bureau will be absolutely international. The place where it is organised will in no wise modify its character. There will not be more French representatives at the bureau because it is in Paris than if it had been in any other town or country. The cost will be defrayed by all the Governments but it is not thought that the sum needed will be sufficiently large to become an obstacle. However, it is somewhat premature to discuss the details. A project for the organisation of the office or bureau will be drawn up at once and it is thought that it will be ready to submit to the different Governments in about three months' time.

The one trouble in the way, the one cause of perplexity, of anxiety, of surprise, and of disappointment, is the fact that the British delegates did not seem to favour the project. In spite of many and persistent questions I could not get any tangible explanation as to their reasons for the sort of opposition which they made. It was stated that they failed to see that there was any need for such an institution or that it would render any service if established. Evidently, if this was all the British delegates said, then they did not think fit to express their real reasons for objecting. Of course, it is easy to understand that the British representatives might imagine that some continental legislatures were disposed to touch questions which in England were not as yet the subject of legal enactment. But even if this were so, the existence of an international bureau to facilitate the collecting and diffusion of information would not have much influence in making the British Legislature follow some continental example. In any case these are but theoretical objections, for in actual practice the position of affairs presents the reverse to this picture. It is the nations of the continent, on the contrary, which have to imitate the British people. We prevent over-pressure by closing almost all places of business on Sunday, by four bank holidays, and there is a weekly half-holiday besides. We limit the hours of labour for women to ten hours by law and for a very [illegible] nine hours by trade-union [illegible] for the continent to attain [illegible] fear that association with continental countries will push the British nation to advance more quickly than it desires. On the contrary, it is the British nation which has every interest in seeing continental countries improve the condition of their working classes. If sanitary laws, by the restrictions imposed, are to augment the cost and difficulty of production for the sake of preserving the health of the producer the only objection that can be raised is that by so doing the business itself may be destroyed. Where there is foreign competition such objections are not altogether devoid of foundation. But in England we already do impose such restriction. Employers' Liability Acts and such laws have long been on our Statute-book. If any nation suffers in competing in foreign markets because of increased cost in production caused by the application of laws for the preservation of health it is assuredly the British nation. Therefore we have no reason to fear the institution of an international bureau because it would tend to assimilate the legislation for the protection of labour and health in the different countries. On the contrary, it would be a great boon to the British nation if the laws of the continental countries that deal with these questions could be brought up to our own level. This would do much to lay the bogey of foreign competition. But in all this I am arguing rather from the point of view taken at the Brussels Congress.

At the Paris Conference the representatives were more concerned with international intercourse, the transit of contaminated persons, merchandise, mosquitoes, or rats, than with the condition of various industries and the injuries resulting therefrom to the workers. But in this also we have everything to gain by the publicity that the existence of the proposed international bureau should provide. For instance, occasions may arise when it would be maintained that some particular sorts of merchandise, old rags, carpets, &c., were capable of conveying a certain disease. Therefore these things before they can be introduced into the country must be disinfected. Some such precaution taken against goods of this kind coming from an Eastern or Red Sea port might be very justifiable but would be very vexatious if applied against Southampton or some other port belonging to a nation advanced in the application of practical sanitation. If rags came from a country where disinfection is not obligatory it may be a matter of some risk to import such articles. Therefore, for this and a multitude of other reasons it may be necessary to take more rigorous precautions against the merchandise coming from one than from another country. But who is to make this selection? Would not an international sanitary bureau assist considerably in the making of such selection and what could England lose in such a process? Do we fear being compared with other nations? We have undoubtedly our weak as well as our strong points, but at least in respect to sanitation we can hold our own in the face of the whole world. Indeed, many sanitary reformers of the continent will welcome the creation of the International Sanitary Bureau as a means of making the sanitary measures taken in England better known on the continent and thus it will be easier to get the continental authorities to act in a similar manner. In fact, it is difficult to see what possible disadvantage there can be in the diffusion of information and establishing intimate comparisons between the efforts made in all countries to protect public health. This can only result in helping those who are behindhand to hasten forwards. Just at the moment when the official representatives of so many nations were endorsing this proposal and preparing to sign the convention in favour of the International Sanitary Bureau a large number of members of the British House of Commons were being entertained in a most magnificent manner by the French Government and by the French people. Nothing could exceed the enthusiasm and the friendliness that prevailed. It really did seem as if old antagonism had been completely effaced and as if the two nations had drawn together for a permanent and hearty friendship. At almost identically the same moment there came an opportunity of giving a practical expression of realising in a small way this very evident desire to work hand in hand, and it was the British representatives who drew back, hesitated, and would not pledge themselves to support the new international form of coöperation intended to promote public health in all countries. Such a work could not help incidentally contributing also to promote the cause of international peace and it is to be hoped that the British Government when better informed will see its way to join heartily, if tardily, the great majority of the other nations in creating an international institution that will be of benefit in developing throughout the world an important phase of civilisation.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Thompson-Yates Laboratories: Death of the Donor.

THE Rev. Samuel Ashton Thompson-Yates, M.A., the munificent donor of the pathological and physiological laboratories to the then University College, Liverpool, which bear his name, died in London on Nov. 22nd at the age of 61 years. Prior to his gift of the laboratories Mr. Thompson-Yates had proved himself an enthusiastic friend of education and was a constant subscriber to the University College fund. He was for many years a member of the court of governors and was one of the first to advocate independence for the College. The funeral took place on Nov. 26th at Highgate Cemetery. Vice-Chancellor Dale, Professor C. S. Sherrington, and Professor Woodward were deputed by the council to represent the University of Liverpool at the funeral obsequies. The flag at the University was hoisted at half mast when the news of his death was received. The laboratories were also closed on the day of the funeral.

Liverpool free from Small-pox.

For the first time for 18 months the medical officer of health (Dr. E. W. Hope) was able to report, at a recent meeting of the health committee of the city council, that there was not a single case of small-pox in any of the city hospitals. The last patient was discharged on Nov. 23rd. The epidemic had been on the decline for some months and for the last four or five weeks only some half-dozen cases were in hospital. It was therefore with much satisfaction that the committee heard of its absolute disappearance. Scarlet fever, on the other hand, is prevalent; there were 391 cases in hospital on Dec. 3rd. The general death-rate of the city for the past week was 22·2 per 1000 of the inhabitants, as against 25·8 per 1000 during the corresponding week of last year.

Liverpool School of Tropical Medicine: Ankylostomiasis among Miners.

At the University of Liverpool on Nov. 27th Mr. Charles Salter gave some results of a tour of inquiry into the outbreaks of ankylostomiasis among miners in Westphalia and Belgium, Professor Ronald Ross being in the chair. Mr. Salter said that the researches of Perroncito at the time the St. Gothard tunnel was being driven showed once for all that the disease was due to the ankylostoma, a worm which adhered to the intestines in the human body. The male of the parasite was from a quarter to one-third of an inch in length and the female was longer and thicker, reaching sometimes a length of half an inch. The female laid between 2000 and 3000 eggs a day, and as these parasites could live in the human body during four or five years their potentiality of increase was very great. Recent research showed that the ova were not capable of reaching the adult stage save in the intestines as a habitat, but the eggs retained their vitality in dirty water for as long as five months. For their development they needed a heat of 68° F. and upwards, a certain supply of oxygen, and exclusion of light. The most favourable hatching medium was, given the requisite heat, damp coal-dust mixed with animal refuse. The supposition that the larvæ could penetrate into the bowels through the wall of the abdomen had been proved by experiment to be baseless. They were introduced into the system through the mouth and the disease owed its propagation to the habit on the part of miners of eating their food with soiled hands. It was chiefly prevalent in warm, damp mines. The symptoms were a complexion of livid grey colour, palpitation, dizziness, loss of appetite, and gastric disturbance, with in bad cases great lassitude. As a result of the epidemic among the miners of Westphalia there were upwards of 17,000 cases this year. The lecturer then described the measures taken by the authorities to cope with the outbreak. The treatment considered safest was the administration of calomel and extract of male fern in alternate doses. This generally produced a cure in about a week. As to prophylactics, the best had been found to be dilute sulphuric acid and ammonia. Both, however, being too expensive to be used as disinfectants on a large scale the only alternative was strict and compulsory rules of sanitation and these, as carried out in German mines, had had a most marked effect. The provision of douche baths, rooms for changing clothing, and properly constructed latrines, as well as mine hospitals, were among the precautions found necessary. He regretted the waiting policy of the Home Office in this country, as prevention would prove far better than cure.

Presentation to Professor A. M. Paterson.

On Dec. 5th the annual dinner of the medical students of the University of Liverpool was held at the Adelphi Hotel, and the occasion was taken advantage of to make a presentation to Professor A. M. Paterson who until three months ago had for more than nine years occupied the position of dean of the medical faculty of University College, Liverpool. Sir William Banks presided and about 120 gentlemen sat down to dinner. Mr. Frank Jeans, the honorary secretary of the dinner committee, presented Professor Paterson with a silver inkstand, a silver flower-bowl, and silver candlesticks. He referred to the great success which had attended Professor Paterson's occupation of the office of dean and the great personal and friendly interest which he had always taken in the welfare of the students. In replying Professor Paterson, who was received with prolonged cheering, said that it was a source of great gratification to him to think that of all the students who had passed through his hands 87 per cent. had duly qualified as medical practitioners. He looked upon it as a favourable sign that amongst medical students in Liverpool the "chronic" had almost entirely disappeared. The evening was a great success, the speeches of Sir William Banks and Mr. Edgar A. Browne being very amusing and highly appreciated.

University of Liverpool.

At the first meeting of Liverpool University court of governors, held on Dec. 5th, Mr. E. K Muspratt (pro-chancellor) in the chair, appeals were made for further financial aid to assist in the development of the university. The university starts its career by taking over investments valued at £275,000 and lands and buildings worth £230,000.

Hospitals and their Rates.

In the issue of THE LANCET of Nov. 28th, p. 1536, reference was made to the remarks of the Lord Mayor (Mr. R. A. Hampson) at the annual meeting of the Hospital Saturday Fund, suggesting the formation of a committee with the object of securing legislation to relieve hospitals from the payment of rates. I understand that a small committee has been formed with that object and will shortly meet at the town hall under the presidency of the Lord Mayor who, as president of the Stanley Hospital, is keenly interested in the question.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Overcrowding of Bedwellty Workhouse.

THE Bedwellty (Mon.) board of guardians has for several years past been aware that some decisive step would have to be taken to increase the accommodation at the Tredegar workhouse. The population of the union in 1901 was 81,820, an increase of 17,219 over the number of persons recorded in 1891, and included within the area of the union are the populous colliery districts of Abertillery, Ebbw Vale, Rhymney, and Tredegar, where there is every prospect of the local industries being still more extended. The overcrowding of the workhouse has been reported upon over and over again during the past three years, not only by the master and the medical officer (Mr. G. A. Brown) but also by the Poor-law inspector of the Local Government Board (Mr. F. T. Bircham). As long ago as December, 1902, it was stated that 17 boys were sleeping in a ward calculated to accommodate only ten and at that time the board room was given up as a sleeping apartment for the inmates and other temporary measures were adopted. At a meeting of the board held on Dec. 2nd last the master reported that there were 355 inmates in the house, although there was only room for 266. Various proposals have from time to time been made to remedy this deplorable overcrowding. The division of the union with the consequent establishment of a separate workhouse elsewhere and the purchase of a large unoccupied house in another portion of the district to be used as a branch workhouse, although suggested, have not been seriously considered and the members of the board of guardians are to be congratulated upon having at last decided to make extensions to the existing buildings upon an adequate scale. The cost is estimated at £27 886 and accommodation will be provided for 100 additional inmates. Properly arranged sick wards and isolation wards will also be erected. It is further proposed to relieve the workhouse by the removal of the children to cottage homes which are to be erected at Tredegar at a cost of £8325. In this group of buildings there are to be four cottage homes, each having accommodation for 15 children and a foster mother. The total expenditure involved will entail a rate of 1½*d.* in the pound for 30 years.

Ankylostomiasis.

The possibility of the introduction of ankylostomiasis duodenalis among the colliers of South Wales has recently been freely discussed in that district and it is especially gratifying to find Mr. William Abraham, M P., the miners' agent, and more popularly known as "Mabon," giving the colliers most excellent advice with a view to prevent any spread of the disease should it unfortunately make its appearance among them. Conferences, too, have been arranged between the colliery owners and leaders of the men in various districts in order to determine what preventive measures should be taken. In a communication to the local press Mr. Abraham states that at a meeting held at the Home Office at the end of November between representatives of the coal owners and of the miners the latter suggested that closets and urinals should be placed near the pit bank and in the pit itself near the pit porch and main passbyes in the return airways, that these places should be examined by the medical officer of health who should also examine any collier suspected of having contracted the disease, and finally that all workmen coming from a district where the disease prevails or has prevailed should be examined by a medical man who should be empowered to place in quarantine any man found to be suffering from the disease. The sanitary committee of the Glamorganshire county council has sent a circular letter to the medical men practising in the county offering the assistance of the Cardiff and county public health laboratory in the diagnosis of suspected cases

Side Windows in Covered Vans.

The Glamorganshire county council, which was the first authority in the country to adopt a by-law prohibiting indiscriminate spitting, is now endeavouring to lessen the number of accidents caused by the drivers of covered vans suddenly altering their direction, unaware that another vehicle, pedestrian, or cyclist is passing. After Jan. 1st, 1904, the following by-law will be in force within the administrative county:—

> Every tradesman's van or other covered vehicle intended to be driven by a person sitting inside thereof shall be so constructed with side windows or otherwise as to enable such person to see the approach of vehicles from behind on either side thereof.

The penalty for not complying with the by-law may be £5 The tradesmen who are particularly concerned—bakers, grocers, and others—appear to resent the adoption of this by-law, but its enforcement cannot fail to be of service.

Glamorganshire County Sanatorium.

The medical officer of health to the Glamorganshire county council (Dr. William Williams) has reported to the sanitary committee of the council in favour of establishing at the cost of the county a sanatorium for consumptives with accommodation for 30 patients. He estimates the cost of the site at £3000 and of the buildings and furniture at £12,000, or £400 per bed. The annual expenditure is put down at £4189.

Swansea Technical College.

The Swansea Technical College is now recognised as a school in which medical students may attend classes in physics and chemistry during the first of their five years' curriculum.

Dec. 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A New Out-patient Department for the Royal Hospital for Sick Children, Edinburgh.

THE out-patient department at the Edinburgh Royal Hospital for Sick Children has grown so greatly since the present hospital was opened some eight years ago that the directors found it necessary to undertake the construction of premises to meet the demands made on the department. Last year 6724 children were attended to in it, while the number of attendances reached a total of close upon 22,000. Not only did the department require enlarging but it required to be refitted in conformity with the present position of scientific medicine. The new department is a two-storey building to the west of the hospital. Patients enter by a south gate inside which there is a covered place for perambulators. Off the entrance open three isolation rooms for children suspected of having infectious disease Medical cases are treated on the ground floor. The medical waiting room measures 36 by 38 feet and a dressing room opens off it which again opens into the room where the physician in attendance sees the patients. This room also has an entrance from the outside for the students and the staff. The drug dispensary is also on this floor. Upstairs the rooms to the south front contain electrical, ophthalmic, and photographic appliances; those to the north are occupied by the surgical department, including [illegible] anæsthetic room, and [illegible] modern necessaries. [illegible] tory for the use of the staff. The floors are of concrete, finished with cement, and the walls are tiled to a height of seven feet. The floors have scuppers and the ordinary angles and corners are rounded, so that the walls can be cleaned by means of the hose. The rooms are heated by means of steam pipes on the low-pressure system and ventilation is aided by extraction fans driven by electricity. The new department, which has been planned and the work carried out with great care, has cost about £6000. It was formally opened on Dec. 8th by H.R.H. Princess Louise, Duchess of Argyle.

Physiology in Relation to the Teaching Profession.

Dr. D Fraser Harris delivered an interesting lecture to the University Education Society of the University of St Andrews on this subject on Monday last Pointing out that the profession of teaching involved the highest physical and moral responsibilities in matters of conduct, he claimed that no science could be more closely related to these same matters of conduct than physiology. The physiology of circulation, respiration, digestion, excretion, and of the central nervous system should all be studied by the teacher if he is to help the State to combat the grave physical defects which the nation as a whole is now alleged to suffer from. Moreover, a study of physiology gives an insight into what is meant by inhibition, the development of which power in his pupils Dr. Harris ranked as the highest function of the teacher. The lecture, which was illustrated by diagrams, was listened to with marked attention and Dr. Harris may be considered to have advanced a powerful plea for knowledge of physiology among the instructors of our young.

The University of Glasgow.

The Right Hon. the Earl of Stair, K.T., LL D., Chancellor of the University of Glasgow, died on Dec. 3rd at Lochinch, near Stranraer, after an illness of five weeks' duration. The Principal communicated the announcement, which had been telegraphed to him by Viscount Dalrymple, to his colleagues at a special meeting the same afternoon. The Senate adopted the following minute as a permanent record of the sad event:—

> The Senate has received with deep regret the intelligence of the death of the venerable Chancellor of the University, the Right Hon. the Earl of Stair, K.T., who died this morning at Lochinch in the eighty-fifth year of his age. Lord Stair had faithfully served the [illegible] The Senate desires to record [illegible]

The clerk of the Senate has forwarded a copy of this minute to Lord Dalrymple conveying at the same time an expression of the Senate's deep sympathy with the family of the deceased earl. Representatives from the Senate, the University Court, and other bodies connected with the University attended the funeral which took place on the following Monday, on which day as a token of respect no classes were held within the walls of the University.

Death of William Douglas Pringle, M.B., B.Ch.Aberd.

Many Aberdeen graduates will learn with deep regret of the death of Dr. William Douglas Pringle, Lieutenant I.M.S., aged 26 years, which occurred at Tientsin, China, on Sept. 3rd last, and news of which has just reached this country. Lieutenant Pringle graduated at Aberdeen in 1900 with distinction in the third and final professional examinations. He was an Anglo-Indian but he rapidly adapted himself to his new surroundings and became one of the most popular men of his year. While at the University he took an active interest in athletics, being a good oar, a strong swimmer, a keen pedestrian, a brilliant shot, and an all-round sportsman. After graduating he passed into the Indian Medical Service, taking the ninth place in the entrance examination. His death was due to dysentery.

Tuberculous Cases in Aberdeen Royal Infirmary.

In connexion with the appointment of managers of the infirmary attention has been directed to the reports of the directors for the past four years, with special reference to cases of phthisis and tuberculous disease. From the figures of the reports it was shown that during the four years 1899 to 1902 there had been 380 cases of phthisis received, out of which five recovered, 214 improved, and 80 died. During the same period 81 patients had been taken away "at desire or having been unfit." The matter of erecting a sanatorium somewhere on Deeside where sufficient and efficient provision would be made for the treatment, arrest, and, if possible, the eradication of the disease and the benefits of which would be within the reach of all, has been under the serious consideration of the directors for some time. Plans of a building have been prepared and negotiations are in progress for the acquisition of land for the erection of a sanatorium to be equipped in the light of the most recent scientific discoveries and experience. Quite recently the directors had a consultation with the medical officer at the head of the sanatorium at Nordrach-on-Dee as to the plans of the proposed building and a large amount of information was placed before the directors which will be of great value when the building comes to be erected. With the comparatively limited resources of the Royal Infirmary it has been impossible to give the full and undivided attention of the staff to the particular branch of disease in question, but on a limited scale the principle of the outdoor treatment of consumptives has already been tried at Woolmanhill and so far the results have been satisfactory, the patients under treatment eating much better and being in every way improved in strength. Sufficient time, however, has not yet elapsed to enable any definite conclusions to be made as to the effect of the treatment. With reference to the small number of recoveries of patients the important fact must be borne in mind that most of the cases which are admitted to the infirmary are already in an advanced stage and therefore practically beyond hope of cure.

Dec. 8th.

IRELAND.

(From our own Correspondents.)

Royal College of Surgeons in Ireland.

At a meeting of the President, Vice-President, and Council of the Royal College of Surgeons in Ireland held on Dec. 3rd the vacancy caused by the death of Sir George Duffey was filled by the appointment of Dr. Michael McHugh to the post of professor of materia medica.

The Granard Nursing Quarrel.

What has been known as the Granard nursing quarrel seems after a duration of nearly 12 months to be now drawing to a close. At a meeting of the guardians held on Dec 7th a letter was read from the Roman Catholic bishop of the diocese which, while blaming the Local Government Board for "a glaring miscarriage of justice," stated definitely that he would not permit the nun nurses to return to the hospital at Granard. After a long discussion and many threatening remarks directed towards the medical officer of the union hospital, whose complaints are looked upon as the cause of the whole trouble, the board decided on appointing a trained nurse to hold office permanently.

Union Medical Officers of Ireland.

A long letter has appeared in the morning papers from Mr. McArdle in which he denounces the recent suggestion of the President of the Royal College of Surgeons in Ireland that union medical officers should be chosen by an examination held by a competent examining board. Mr. McArdle considers that such an arrangement would be a most unfair interference with the rights of the popularly elected guardians and would be "contrary to the spirit of the age." However that may be, there can be no doubt that in the election of a Poor-law medical officer in Ireland the very last thing that is considered is the candidate's merit as evidenced by his career as a student or by the value of the medical qualifications which he holds. Practically all those elections are decided by political or religious motives, or by the fact that the candidate has some influential relative on the board. After his election the same factors settle his career. The poor for whose sake he is appointed may find him stupid and incompetent. It does not matter so long as he avoids dismissal by the Local Government Board and he has no sort of incentive to do better—promotion being unknown in this unique service. In the circumstances it is not surprising that the President of the Royal College of Surgeons should have made a suggestive attempt to improve such a state of things and to solve an important but most difficult problem.

The Sterilisation of Milk in Schools.

At a meeting of the committee of the Dublin branch of the National Association for the Prevention of Tuberculosis held at the Royal College of Physicians, Kildare-street, on Dec. 1st, attention was drawn to the recently published annual report of the Registrar-General for Ireland, from which it appears that the death-rate from tuberculosis during the year 1902 was 2·7 per 1000 of the population. The committee also considered the important question of the dissemination of the disease by means of infected milk and the following motion was passed unanimously:—

> As tubercular infection is the most frequent cause in young people, not merely of ordinary consumption but of bone and joint diseases, meningitis, and many forms of lung disease not ordinarily registered as consumption, and as milk derived from even apparently healthy cows may contain the tubercle bacillus and is believed to be capable of infecting human beings, and especially the young, with tuberculosis—Resolved—That the attention of the principals of boarding schools and public institutions for the young be called to the above facts and to the desirability of sterilising milk before its use by those under their charge. Further, that they be informed that this advice is in conformity with regulations issued last year by the Minister of Public Instruction in France.

Health of Belfast.

At the usual monthly meeting of the city corporation of Belfast held on Dec. 1st it was reported that the town clerk was directed to make inquiries as to the possibility of obtaining the services of a medical expert having experience in connexion with the treatment of consumption in sanatoriums to act in conjunction with the medical superintendent officer of health in advising the health committee on these matters. The health of the city during the past five weeks had continued satisfactory. Typhoid fever had decreased as well as scarlet fever and the type of the latter disease was mild. The death-rate was 17·9 per 1000. There were 1030 births and 618 deaths (including 54 from zymotic disease, 95 from phthisis, and 125 from diseases of the respiratory organs). The council has decided to contribute £300 for the removal of decaying sea-weed from the Cultra foreshore in Belfast Lough. No discussion has so far taken place on Professor J. Lorrain Smith's report.

Attendance on Children's Hospitals.

For several years the Senate of the Royal University of Ireland obliged candidates to have a certificate of having had "personal charge" of six cases of diseases of children and of six cases of diseases of women. A few years ago the rule suddenly (no one can explain the reason) disappeared from the Royal University of Ireland calendar and now a "personal" attendance on midwifery cases is all that is required, notwithstanding the fact that a separate paper is given on gynæcology and diseases of children. The absurdity of the rule is that students must have "personal charge" of at least ten fever cases and yet no separate paper or examination is held on fevers. The clinical teachers in Dublin are anxious to have the former rule re-enacted.

The Royal Victoria Hospital, Belfast.

The lot of the resident surgeons in charge of the extern department is rapidly becoming a most difficult one owing to the exacting demands of the working-class subscribers who criticise the treatment, make the most flimsy complaints, and in many cases demand admission, not from the urgent need of their accidents or ailments but solely on the ground that they are subscribers. Recently the Belfast trades' council publicly discussed the way in which one of its members had been treated at the hospital and sent a deputation to the board of management demanding an inquiry which was held, the upshot of which was to exonerate house surgeons, nurses, and all concerned with the Royal Victoria Hospital. The result of the Workmen's Liability Act has been to cool largely the enthusiasm of employers for hospitals, as they are obliged to pay a heavy insurance now to protect themselves against accidents to their workers, and they naturally feel that the workers themselves should contribute to the upkeep of the places in which they are treated, while as a natural consequence the employers are beginning to regard hospitals as clubs, at least this is what is rapidly approaching in Belfast. The time of the resident superintendent of the hospital and of busy members of the board of management is being constantly taken up and absurdly and uselessly wasted in settling the most miserable and utterly without foundation complaints. As a natural consequence the old idea that hospitals are charities will soon disappear.

Army Medical Examinations.

Professor T. Sinclair of Belfast has been appointed examiner in surgery at the army medical examinations.

Dec. 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Births and Deaths in France for 1902.

STATISTICS of the population of France for 1902 have just been published. There are 83,944 more births than deaths, or an increase over the figures for 1901 of 11,546. This favourable result is not due to an increase in the number of births but to a marked diminution in the number of deaths. As a matter of fact, in 1902 the number of births was 11,896 less than in 1901 and the number of deaths was 22,442 less than in 1901. The increase in the birth-rate is therefore only apparent, for in reality the birth-rate has again diminished. In 1902 the population increased by 22 per 10,000 inhabitants, a figure slightly higher than that for 1901, which was 19 per 10,000. Even this figure, however, was better than the mean for the decennium 1891–1900, when it was only 6 per 10,000, for during the decennium in question there were four years in which the deaths exceeded the births. Despite the small progress shown of late the state of France as regards increase of population remains unsatisfactory, especially if it be compared with that which obtains in other countries of Europe.

The Society for Aiding the Wounded.

In 1899 the Society for Aiding Wounded Soldiers founded at Paris in the Rue de Vanves a dispensary under the charge of Dr. Guyon, a member of the Institute and of the Academy of Medicine. This dispensary did such excellent work in instructing ladies who were willing to act as nurses with the ambulances in time of war that six provincial towns followed the example of Paris in providing dispensaries for training ladies of the red cross. At Lyons, Marseilles, Reims, Cherbourg, Vannes, and Evreux dispensaries are at work and give certificates to nurses when trained. This year the following additional towns have followed suit: Bordeaux, Grenoble, Nancy, Rennes, St. Malo, Boulogne-sur-Mer, Epernay, Tours, and Le Mans. It is evident that eventually all provincial towns of any importance will do the same.

Dr. Marmorek's Serum.[1]

The meeting of the Academy of Medicine held on Dec. 1st was almost entirely devoted to a discussion upon Dr. Marmorek's serum, of which I have already given your readers an account. M. Dieulafoy gave a *résumé* of the conclusions to which he had come after seeing some experiments undertaken in his wards with his leave by Dr. Marmorek. They are anything but encouraging. Patients who exhibited pyrexia did not improve and one patient in whom the temperature was not raised showed a rise after the first injection. Expectoration increased to double or triple its former quantity and as for the evolution of tuberculous lesions secondary lesions appeared around the primary foci after the injection of the serum. Out of seven patients treated two survived, the other five dying at periods varying from two to 11 months. Dr. Marmorek then made some experiments upon guinea-pigs at the Hôtel Dieu. Eight guinea-pigs were infected with the bacillus tuberculosis in culture, four were then given the serum and the other four were kept as controls. The four which had received the serum died before those which had not received it. M. Le Dentu followed with his experience which only related to one case. The patient suffered from tuberculosis of the upper end of the tibia. He received 15 injections of serum without showing any improvement and Dr. Marmorek then desisted. The surgeon then scraped out the tuberculous focus and promptly the patient, who was saturated with the so-called antituberculous serum, showed an exacerbation of symptoms. First the knee became invaded, then the lungs; the leg was amputated and the patient died two months after the serum treatment had begun. M. Monod, who followed, said that in sundry cases of articular and glandular tuberculosis he had observed some improvement but no cure. It is well known, however, that localised forms of tuberculosis in the limbs or in the glands often tend to spontaneous recovery with rest and slight surgical interference. M. Hallopeau tried the serum in seven cases of tuberculosis of the skin which were under his care at the St. Louis Hospital. Some cases showed no results but in one patient ulcers appeared at the sites of inoculations which were indurated just as if tuberculosis virus had been inoculated. At the meeting held on Dec. 8th M. Lucas Championnière said that one patient under his care appeared to improve at first but at the end of five days he died from tuberculous meningitis.

Crookes's Bulbs for Radio-therapy.

In cancer of the tongue, the uterus, and the rectum treatment by the x rays is almost impossible, for these organs are so deeply seated and are so protected by healthy or bony tissues that application of the rays is almost impossible without running the risk of setting up severe x ray burns. To obviate this difficulty M. Oudin has had constructed some Crookes's bulbs fitted with an ebonite handle which the surgeon can hold and so apply the rays locally without the risk of bringing about x-ray burns of the overlying tissues. M. Oudin exhibited these new bulbs at a meeting of the Academy of Sciences which was held on Nov. 25th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Psycho-therapeutics in General Practice.

AT the last semi-annual meeting of Swiss medical men which took place at Olten on Oct. 31st and which was attended by over 200 medical men from all parts of Switzerland Professor Dubois of Bern, lecturer on diseases of the nervous system, spoke on Psycho-therapeutics. He disregarded hypnotism and referred solely to treatment by suggestion of various nervous ailments, such as neurasthenia, hysteria, and some forms of hypochondriasis, which he thinks should be considered as psychical affections and not merely as nervous ailments. A correct diagnosis which carefully excludes organic disease is of great importance, as also is the fact of impressing the patient with the curability of his ailments. In short, convince him and he is cured. This doctrine he demonstrated by reference to remarkable cures effected in the space of a few weeks of patients of many years' duration. The medical man treating such cases must have a great deal of tact and a certain amount of will force and patience, and must not be nonplussed by the various complaints of his patients. He must be well versed in science, literature, religion, and philosophy, and enter into all the details of the ailments complained of and make use of the information thus obtained to effect a cure by appealing in turn to the patient's will force, to his affections, and to his sense of duty. The practitioner should devote considerable time daily to each patient and should avail himself of psychical treatment on every occasion and should not waste his patient's time in trying all sorts of so-called cures. All other systems of treatment in vogue only tend to confirm the patient in his belief that he is seriously ill and make him a helpless invalid who is a burden to himself and a distress to his fellows. With regard to special treatment Professor Dubois referred his audience to his "Leçons de la Psychonévrose." At the end of his lecture he made the astonishing statement that he had never been obliged to resort to hypnotic medicine, such as bromides, chloral, sulphonal, &c., to procure sleep for his patients, but that suggestion had always proved successful. His remarks well
ver-increasing
obvious that
r words, that
have to be content to march at
of his able instructor in psycho-
therapeutics. In any case this form of treatment will be welcomed by all those medical men who have many reasons for distrusting and discrediting hypnotism.

Zürich, Dec. 5th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical News.

LITTLE of medical interest has occurred during the last month. The small-pox epidemic seems to have died out in Tasmania and no fresh cases of plague have occurred in any of the States. The Bill to amend the Lunacy Act in Victoria, an outline of which was given last month, has been read a second time in the Legislative Assembly and discussed in Committee. Some opposition was shown to the provisions for the constitution of a Board of Lunacy and further consideration was postponed.

---

[1] Dr. Marmorek's original paper appears in full at p. 1642.—ED. L.

Health Society of Victoria.

The annual meeting of the Health Society of Victoria was held on Oct. 10th. His Excellency the Governor presided and gave an interesting address, in which he observed that statistics showed that public sanitation was steadily diminishing the death-rate, but there was also need for bringing home to the people the necessity for regulating their own lives in accordance with well-known principles of hygiene—what was called "personal hygiene"—and that was what the society was trying to accomplish. He believed the first principles of sanitation should be taught in the schools. He did not see why the pulpit should not be sometimes employed for teaching obedience to the laws of health, which were the laws of God. The more healthy a community was as a whole the more virtuous it was likely to be. The report of the council stated that there had been an increase in membership during the year. The usual series of "health lectures for the people" had been given and meetings for women had been held in the suburbs.

Hospital Affairs.

Hospital Sunday, Oct. 24th, in Melbourne was, as it usually is, a wet day. The collections, however, amounted to very nearly the same as last year, a little under £4000. His Majesty the King has been graciously pleased to confer the title "Royal" on the Prince Alfred Hospital, Sydney. It has been found that the system of having clinical assistants at the Prince Alfred Hospital has not been a success and the board of directors has decided at the termination of the present appointments to abolish the positions and to appoint additional honorary assistants to those departments which need them. The conference of delegates from the hospitals on the proposed Hospitals Amending Bill held its final meeting in Melbourne. The recommendations of the subcommittee (which were outlined in a former communication) were agreed to, except the most important one of all, that relating to the mode of election of the honorary medical staff. The committees of the metropolitan hospitals were all so hostile to the proposal of an electoral college that it was abandoned by the conference. It affirmed that the honorary staff should *not* be elected by the subscribers.

Obituary.

Mr. William H. Goode, B.A., M.D., M.Ch. Dub., died at his residence, Macquarie-street, Sydney, on Oct. 13th, after a prolonged illness. Dr. Goode, who was a native of Ireland, was educated at Trinity College, Dublin, where he graduated as M.B in 1867 and M.D. in 1876. The following year he obtained the diploma in State medicine. His early career was spent in the Royal Navy. He served on H.M.S. *Dido* on the African coast and subsequently on the Australian station. He retired from the navy in 1878 and settled in Sydney where he soon had an extensive practice. He was one of the first surgeons to the Prince Alfred Hospital. Afterwards he was surgeon to the Sydney Hospital and to the Hospital for
...ldren. For many years he was medical officer to the
Asylum. From the commencement of the Sydney

fault and always ready with a joke. He endeared himself to all his patients and was a type of man the country can ill afford to lose.

Robert Henry Ritchie was born at Bega in New South Wales. His medical education was begun at Guy's Hospital and School, London, and finished at Melbourne University, where he graduated M.B. in 1894. After graduation he was appointed resident medical officer to the Melbourne Hospital. He then settled in Horsham and was surgeon to the local hospital. In spite of bad health he did some excellent work and contributed several papers to the Medical Society of Victoria. He was the first surgeon in Australia to perform amputation of a leg under spinal cocainisation. Personally he had a most winning manner and a delightful disposition. His ability was far above the average and but for his poor health he would undoubtedly have taken a very high position. The cause of his death was pulmonary tuberculosis.

Nov. 3rd.

Medical News.

TRINITY COLLEGE, DUBLIN.—At the final examination in midwifery held in Michaelmas term the following candidates were successful:—

Thomas H. Gibbon, George B. M'Caul, Reginald H. Lee, Herbert St. M. Carter, David Gray, Harry R. Nelson, Philip S. Stewart, Winslow S. S. Berry, Thomas C. A. Sweetnam, Samuel H. Vickery, Frederick F. C. Willington, John C. Hall, Frederick W. Bury, and Herbert Stone.

UNIVERSITY OF CAMBRIDGE.—At the congregation on Dec. 5th Mr. J. M. Martin, Peterhouse, received the M.D. degree. Dr. W. L. Dickinson, Dr. H. D. Rolleston, and Dr. T. H. Kellock have been appointed as additional examiners for the third M.B. examination.

VACCINATION STATIONS.—At the meeting of the Chard board of guardians held on Nov. 23rd it was resolved to send to every union in the south-west of England a copy of a motion recently passed by the guardians in favour of reverting to "stational" vaccination, in consequence of the increased cost of vaccination since the passing of the Vaccination Act.

ATTEMPTED MURDER OF A MEDICAL MAN.—Mr. Justice Darling took a serious view of the attempted murder of Mr. George Whittenbury White at the Fir Vale Workhouse Infirmary, a short account of which was published in THE LANCET of Nov. 28th, p. 1545. On the conviction of the prisoner by a jury of attempt to murder, Mr. Justice Darling sentenced him to penal servitude for life. Punishment has here followed quickly upon the heels of crime.

SPECTACLE MAKERS' COMPANY.—Alderman Sir George Faudel-Phillips presided on Tuesday last at the Mansion House at a meeting of the special sight-testing committee appointed by the Spectacle Makers' Company to consider the advisability of including sight testing in the company's syllabus. The witnesses examined by the committee have expressed themselves, under certain limitations, in support of the movement, in regard to which it is stated that oculists and the trade will be consulted.

MEDICO-LEGAL SOCIETY.—At a meeting of this society held on Dec. 8th at 20, Hanover-square, W., Sir William J. Collins, the President, in his address commented upon the width and possibilities for development of forensic medicine; he hoped it would soon assume its legitimate status in the medical curriculum. The society should deal with such subjects as (1) coroners' law amendment; (2) the present position of professional secrecy; (3) the attitude to be taken with regard to secret remedies; and (4) other "residual" topics neglected alike by lawyers and medical men. He paid an eloquent tribute to the life-work and memory of Mr. Herbert Spencer. Mr. John Troutbeck (treasurer) read a paper on Inquest Juries. After great experience he defended their present utility, showing, however, that in several directions they had lost their primitive significance and importance. The average voter was well qualified to serve as a juror; a large jury was a check upon "cranks"—he would consider seven or nine as sufficient. The lack in London of centralisation of medico-legal work was as deplorable as its opportunities were unique.

The President, Mr. Walter Schröder, Mr. William Lewis (of the Treasury), Dr. Harvey Littlejohn, Dr. F. J. Smith, Mr. W. A. Brend, and Mr. S. B. Atkinson continued the discussion. In his reply Mr. Troutbeck urged either a better class of registrar or early official medical inspection of all certificates of death.

BRISTOL ROYAL HOSPITAL FOR CHILDREN.—It is hoped to raise £4000 for the endowment of the "Mark Whitwill Ward," which is the form of memorial that has been decided upon to perpetuate the memory of the late Mr. Mark Whitwill. Up to the present time £2788 have been received.

CONFERENCE ON THE TRAINING AND SUPPLY OF MIDWIVES.—Lord Monkswell, chairman of the London County Council, took the chair on Dec. 2nd at a conference convened by the Association for promoting the Training and Supply of Midwives to consider the methods and means for promoting the training and supply of midwives. The conference was held at 2, Cromwell Houses, London, and was well attended by ladies and others interested in the movement. The chairman in a few opening remarks asked for an expression of the opinion of those present as to whether the London County Council should administer the provisions of the Midwives Act in the metropolis or whether the borough councils should be intrusted with the work. Later in the course of the proceedings the chairman put the question directly to the meeting and it was found that those present were in favour of the London County Council discharging the duties to be carried out under the Act, only one lady voting against it. The two principal speakers in favour of the London County Council being the authority intrusted with the administration of the Midwives Act were Mrs. W. Bruce and Miss Rosalind Paget who strongly urged the step because it was necessary in the metropolis to insure the control of the midwives under one central authority. Most of the speeches had reference to a motion which was to the effect that the meeting was in favour of the work and aims of the Association for promoting the Training and Supply of Midwives and would do what was possible to further the work of organising the training of midwives on a sound basis. This motion was proposed by Miss A. Clifford, seconded by Lady Mary Glyn, and carried unanimously. Lady Mary Glyn, in the course of her remarks, expressed the strongest disapprobation of any scheme that involved "mixing up" midwifery with district nursing. Mrs. W. Bruce said that a good standard of training ought to be maintained and pointed out that a large sum of money would be required to secure the fulfilment of the objects of the association. Dr. J. R. Kaye of Wakefield sent a letter in which he urged that midwives should be utilised as district nurses, because in small villages it would be impossible for the midwife to make a living without also acting as a nurse. Miss Amy Hughes gave her reasons in great detail why nursing and midwifery should be combined, provided efficient supervision by fully competent women was secured. Mr. Shirley F. Murphy severely criticised the Midwives Act, calling it "An Act for the Prevention of the Practice of Midwives." He showed how impossible it would be to carry out the provisions of the Act in the case of many of the midwives who had been admitted on the roll by reason of the fact that many of them were unable to write and therefore would be unable to fulfil the requirements of the Act in regard to keeping a reasonable note of the cases which they attended. With reference to the supply of midwives he put the whole matter to the meeting very tersely by saying that the supply would depend upon the fees they were likely to receive. Sir Michael Foster deprecated the stringency of the regulations concerning midwives and observed that although it might be right to discuss the high standard the midwife of the future should attain at the present moment it was not wise to be too exacting. Provision had to be made for midwives in country districts and it had to be recognised that a midwife living in [illegible] rom midwifery alone. [illegible] undesirable that nurs- [illegible] but midwifery could be mixed up very well with looking after a small shop, or lodgers, or a husband. Funds were necessary, not to pauperise midwives but to enable women who by nature were qualified to be midwives to be trained so that they might make a living. Sir Michael Foster concluded with the following words: "Do not demand any extraordinary expenditure on the part of these women before they can begin to earn what will afterwards be a very limited livelihood." Many of the ladies availed themselves of the cordial invitation of the chairman to take an active part in the deliberations and the proceedings were followed with the closest attention by the audience.

BORIC ACID IN MILK.—The sanitary committee of the Exeter city council has just issued notices to the milk vendors in that city pointing out that the use of boric acid in milk is an offence under the Sale of Food and Drugs Act.

BY-LAW AGAINST SPITTING.—The Bristol city council at its meeting on Nov. 24th adopted a by-law against spitting in public places, the penalty being £1 for each offence.

BELGRAVE HOSPITAL FOR CHILDREN.—On Dec. 1st this hospital in its new situation in the Clapham-road, S.W., was opened for the reception of patients. The inauguration ceremony was conducted by the Bishop of Rochester who in the course of a few remarks said that the hospital had had a previous inauguration when Princess Henry of Battenberg came there in July last; the present occasion was of a simpler character and was a gathering together of friends and neighbours of the hospital to start it on its career of useful work with words of prayer and benediction. He said that though the Belgrave Hospital was an old one it was a new one in its present position and it had come to fill a much felt want on that side of the Thames. It would be found to be well arranged in every respect, its one fault being that it was not yet completed. £40,000 had been spent and it was earnestly hoped that the funds necessary for its completion would soon be forthcoming as an institution could not be said to be worked economically until all its capabilities were utilised to their fullest extent. The company then visited the wards, which already had two small occupants, and the operating theatre which with its fittings and sterilising chamber was presented by Mr. C. T. Dent to the hospital.

UNIVERSITY OF OXFORD.—An examination for a Radcliffe travelling fellowship of the annual value of £200 and tenable for three years will be held in Hilary term, 1904, commencing on Tuesday, March 1st. Candidates must have passed all the examinations required by the University for the degree of Bachelor of Arts and for the degree of Bachelor of Medicine. They must also have been placed in the first class in one, at least, of the public examinations of the University or have obtained some prize or scholarship within the University unattached to any college or hall and open to general competition among the members of the University. The successful candidate must before election declare that he intends to devote himself during the period of his tenure of the fellowship to the study of medical science and to travel abroad with a view to that study. The Regius professor of medicine and the examiners, two months before the expiration of the second year after the election of each fellow, present a report on the work done by him to the electors, who may, if they think the report unsatisfactory, declare the fellowship forfeited. The examination will occupy three days. Papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay. There will also be a practical examination in pathology. Intending candidates should send their names, addresses, and qualifications to "The Radcliffe Examiners, University Museum" on or before Tuesday, Feb. 9th, 1904.

HOSPITAL FOR CHILDREN WITH HIP DISEASE, SEVENOAKS.—The committee of management of this hospital has just appealed for help owing to the financial depression of last year and to the heavy tax on the giving capacity of local friends for the erection of the new building (the cost of which, we understand, has been about £10,000 and which was opened in 1902). Of 56 patients treated last year 33 were from London and of the remainder only six belonged to Sevenoaks. The staff being largely voluntary the expenses of management are small and the cost per patient averages 17s. The charge has been fixed at 7s. a week to make it possible for working people to send their children to the hospital or for charitable people to help them to do so. Of the 56 patients already spoken of as treated last year 17 were discharged as cured or convalescent, nine were otherwise dealt with, and 30 remained in hospital. The committee claims that the great feature of the hospital is that the length of treatment is much greater than is possible in large hospitals, owing to so many urgent cases pressing for admission into the latter, which causes hip cases sometimes to be discharged before they are permanently benefited. Anybody interested is invited to go to the hospital and to see for himself what is being done there. This certainly seems to be a charity well worthy of support and the fact that a comparatively large number of cases come from London ought, we think, to appeal to Londoners.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Acland, John McKno, M.R.C.S., L.D.S. Eng., has been appointed Honorary Surgeon Dentist to the Royal Devon and Exeter Hospital.

Andrew, Henry, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Anæsthetist to the Royal Devon and Exeter Hospital.

Carling, Albert, M.A., M.B., B.C. Cantab., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Queen Elizabeth Hospital and the Red Maids' Schools, Bristol.

Davies, Edward, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Honorary Surgeon Dentist to the Queen Adelaide's Dispensary, Pollard-row, Bethnal Green, E.

Dyball, Brennan, M.B., B.S., L.R.C.P. Lond., F.R.C.S. Eng., has been appointed Honorary Anæsthetist to the Royal Devon and Exeter Hospital.

Edwards, Arnold, M.D. Vict., Ch.B., has been appointed Honorary Assistant Surgeon to the Manchester and Salford Lock Hospital.

Heilborn, W. E., B.A., M.B., B.C. Cantab., has been appointed Anæsthetist to the Royal Infirmary, Bradford.

Martin, Robert, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Banbridge Dispensary District.

Morgan, Frederick Charles, L.R.C.P. Lond., M.R.C.S., has been re-appointed Resident Medical Officer to the Eastville Workhouse by the Bristol Board of Guardians.

Perrott, Charles John, L.R.C.P., L.R.C.S. Irel., has been re-appointed Medical Officer of Health for Kingswood.

Roberts, J. Lloyd, M.D., B.S., B.Sc., B.A., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Honorary Physician to the Royal Southern Hospital, Liverpool.

Sequeira, James H., M.D., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Physician in Charge of the Skin Department of the London Hospital.

Solly, Reginald Vaughan, M.D., B.S., L.R.C.P. Lond., F.R.C.S. Eng., has been appointed Honorary Medical Registrar and Pathologist to the Royal Devon and Exeter Hospital.

Walker, F. A., L.R.C.P. Edin., M.R.C.S., has been appointed Certifying Surgeon under the Factory Act for the Weymouth District of the county of Dorset.

Williams, Frederick Mann, M.R.C.S., L.R.C.P. Edin., D.P.H. Cantab., has been re-appointed Medical Officer for the Plymouth Port Sanitary Authority.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Army Medical Service.—Examination of Candidates for not less than 30 Commissions in the Royal Army Medical Corps.

Birmingham, Jaffray Branch of the General Hospital, Gravelly Hill.—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing.

Bradford Royal Infirmary.—House Physician, unmarried. Salary £100 per annum, with board and residence.

Bridgwater Infirmary.—House Surgeon. Salary £80 a year, with board and residence.

Bristol Royal Hospital for Sick Children and Women.—House Surgeon. Salary £120 per annum, with rooms and attendance.

Chelsea Hospital for Women, Fulham-road, S.W.—Registrar. Honorarium £40 per annum.

Derbyshire Royal Infirmary. — Senior House Surgeon. Salary £100 per annum, with apartments, board, &c. Also Assistant House Surgeon for six months. Salary at rate of £60 per annum, with apartments, board, &c.

Edinburgh, University of.—Additional Examinerships in Materia Medica and Clinical Surgery.

Evelina Hospital for Sick Children, Southwark, S.E.—Eight Clinical Assistants.

Great Northern Central Hospital, Holloway, N.—Senior House Surgeon, Junior House Surgeon, and Junior House Physician, all for six months. Salary of senior officers at rate of £60 per annum, of junior officers £30 per annum, with board, lodging, and washing. Also Assistant Anæsthetist. Honorarium 10 guineas per annum.

Great Yarmouth, County Borough of.—Medical Officer of Health, Medical Officer of the Borough Isolation Hospital, and Port Medical Officer of Health. Salary £400 a year.

Hospital for Consumption and Diseases of the Chest, Brompton. —Resident House Physicians for six months. Honorarium of £25.

Indian Medical Service, India Office, London.—Examination for not less than 20 Commissions in His Majesty's Indian Medical Service.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100, with board and lodging.

Liverpool Cancer Research.—Assistant Director. Salary £200 per annum.

Liverpool Infectious Diseases Hospitals. — Assistant Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and lodging.

Metropolitan Hospital, Kingsland road, N.E.—Assistant Surgeon.

Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead, N.W.—Male Resident Medical Officer. Honorarium £60.

Newport and Monmouthshire Hospital.—Assistant House Surgeon, Salary £70 per annum, with board, residence, and washing.

Northampton General Hospital.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, attendance, and washing.

North-Eastern Hospital for Children, Hackney-road, Bethnal Green, E.—Surgeon.

Norwich, Heigham Hall Private Asylum.—Assistant Medical Officer.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

Queen's Jubilee Hospital, Earl's-court, S.W.—House Surgeon for six months, renewable. Salary at rate of £52 per annum, with board, residence, and washing.

Royal Eye Hospital, Southwark, S.E.—Refraction Assistants. Honorarium £40 for the year 1904. Also Honorary Clinical Assistants.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City-road, E.C.—Assistant Surgeon.

St. George, Hanover square, Provident Dispensary, Little Grosvenor-street, W.—Resident Medical Officer. Salary £100, with allowance about £80, and residence.

St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.—Honorary Assistant Physician or Honorary Assistant Surgeon.

St. Mary's Hospital Medical School, Paddington, W.—Lecturer on Physics and Assistant Lecturer on Chemistry. Salary £100 per annum.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent-garden, W.C.—Junior House Surgeon for six months, renewable. Salary at rate of £50 a year, with board, lodging, and washing. Also Clinical Assistants for Out-patients for six months.

Salford, County Borough of.—Assistant to the Medical Officer of Health. Salary £200 per annum.

Seamen's Hospital Society ("Dreadnought"), Greenwich, S.E.—Junior Resident Medical Officer. Salary £40 per annum, with board, residence, and washing.

Sheffield Royal Hospital.—Assistant House Physician, unmarried. Salary £50 per annum, with board and lodging.

South Devon and East Cornwall Hospital, Plymouth.—House Surgeon. Salary £100, with board, residence, and washing.

Wolverhampton and Staffordshire General Hospital.—Assistant House Physician for six months. Honorarium at rate of £75 per annum, with board, lodging, and washing.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory Act at Hanley, in the county of Stafford; at Cockermouth, in the county of Cumberland; and at Castle Bytham, in the county of Lincoln.

Births, Marriages, and Deaths.

BIRTH.

Pridie.—On Dec. 7th, at Wansford, Northamptonshire, the wife of H. Hampden Pridie, M.B., of a son.

MARRIAGES.

Gavin—Stevenson.—On Dec. 3rd, at the Mission Church, Ahmadabad, Neil Murphy Gavin, F.R.C.S. Edin., to Maud Muriel Stevenson, M.B., Ch.B., daughter of the late Rev. W. Fleming Stevenson, D.D., Dublin.

Novis—Tunstall.—On Dec. 1st, at St. John's, Upper St. Leonards, Thomas Shepherd Novis, Captain I.M.S., 2nd *Bo. Lancers*, to Margaret Anne, youngest daughter of the late Captain Anthony Tunstall of Brighton.

Payne—Howe.—On Dec. 5th, at St. George's, Hanover-square, W., Ernest Le Fevre Payne, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., to Helena, daughter of the late George Howe, of Brooklands, Cheshire

DEATH.

Newman.—At Stamford, on Dec. 3rd, 1903, William Newman, M.D Lond.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE LIGHT CURE AND ELECTRO-THERAPEUTIC INSTITUTE, LIMITED.

A PROSPECTUS has been filed with the registrar of joint-stock companies and a copy has been forwarded to us setting out the advantages of securing shares in an institution called "The Light Cure and Electro-Therapeutic Institute, Limited." The *directors* are Sir Edward Noel Walker, K.C.M.G., formerly Lieutenant-Governor of Ceylon; *Mr. J. W. Sidley* and Mr. J. F. Shone, both of Hampstead; and Mr. Alderman D. S. Ward of Harrogate. The objects of the institute are to provide light *cure and the* more modern methods of electrical treatment for the general public, and to supply electric light and heat baths as substitutes for the Turkish bath. It is stated that the institution will be under *the constant supervision* of a thoroughly qualified medical gentleman with special experience, who *has* placed *his* services at the disposal of the institute. He is a *brave man. If this institution proposes to* carry on the treatment of all the dangerous and chronic conditions *for which light* cures and electro-therapeutics *have* been recommended, so far as we can *see it will do* an extensive trade as a quack association. Undoubtedly the prospectus attempts to provide for the [illegible] pervision of this thoroughly [illegible] t be remembered that *if* the [illegible] *s that satisfy the* General [illegible] medical man will cease to be [illegible] at all. It appears to be [illegible] having "gout, rheumatism, lumbago and sciatica, catarrh and influenza, anæmia, obesity, neuralgia, insomnia, hysteria, and nervous affections generally" should have *resort to the electric light* baths of the institute; and the prospectus continues in its next paragraph. "The estimate *arrived* at and checked by experts ..... shows a very large profit upon the *proposed* capital." We can quite imagine that an institution proposing to embark in the West-end of London upon the treatment of the public generally, when suffering from such a list of diseases as that which we have set out, might make large profits. "*The unique character of the institute* and the style in which all the arrangements will be carried out should attract the patronage and support not only of the general public but also of the wealthy and fashionable circles," says the prospectus, and we think that the probabilities of the case are well gauged. But the question that concerns *our* readers is, Might the institute not do, as well as a good trade, a *great deal of damage? Can* we not imagine a member of the public, who thinks that his "anæmia" *or his "obesity" constitutes* his disease, walking off to the institute and paying his two guineas or his five *guineas for a course* of treatment that is especially bad for his general condition? The prospectus suggests that patients should be *sent* to the institute by medical men, but it does not suggest that the handsome estimated profits will be obtained if *only* such patients *are received*, while *it is quite clear that the institute* proposes to *do a* large medical business. The public can choose their own disease out *of a long* catalogue and can have any treatment they like if they pay *for* it. We need hardly indicate to our readers that such an *institute is not a thing to be joined*, and we shall be very much surprised to *learn that* any *medical officer* whose name is on the Register will be *found to* work for it. Such an institution can only be made really useful to the public if the management is in the hands of a strong *medical and scientific directorate.*

THE BRITISH MEDICAL BENEVOLENT FUND.

THE Treasurer (Dr. S. West, 15, Wimpole street, London, W.) begs to acknowledge the receipt of the following further special donations to the Fund in response to Sir William Broadbent's appeal:—

	£	s.	d.		£	s.	d.
Sir Anderson Critchett ...	10	0	0	Mr. J. B. H. Davson (Sierra Leone)	5	0	0
Mr. Morton Smale	5	5	0	Mr. W. F. Brook	1	1	0
Mr. T. Corbett	5	5	0				
"Thankoffering"	5	5	0				

QUEEN'S HALL CONCERTS

ALL lovers *of music owe a debt to Mr. Robert Newman* for the admirable concerts which he gives them. The Symphony concert on Nov. 28th was chiefly remarkable for a brilliant performance of Bach's Brandenburg Concerto No. 3. How the master of music's work was played it is needless to particularise. On Dec. 2nd the testimonial concert was given to Mr. Newman than whom nobody, with the possible exception of Sir August Manns, has ever better earned such an honour. The hall was very full and the programme was excellent with the exception that it was too *long. To ask a hearer to listen for two and a half* hours to such complex and emotional music as Beethoven's Egmont overture, Tchaikowsky's Pathetic Symphony, Wagner's Tristan overture, with the Liebestod and the Tannhauser overture with the Venusberg music is too much. Other items were the Casse Noisette suite and the Meistersinger overture. The former, though comparatively simple, makes demands on the mind by reason of its curious orchestration, *there being striking* contrasts of tone colour, such as, for instance that obtained by a *conversation* between a celeste and a bass clarionet. Few persons consider what a wonderful analytical power the ear of one accustomed to listen to a big orchestra possesses. Not only can he tell at once what instrument out of some 15 different *kinds is playing but he can detect any variation in pitch. This* analysis, though carried out automatically, is tiring, and we think that *those responsible* for orchestral programmes should never arrange a concert of more than one and a half hours' duration. Mr. Wood is a master conductor and his band is as good as a band *can be*, but *there is* no use in working a *willing horse to* death. All concerned made the testimonial concert a success and we *cordially congratulate them.*

THE POOR-LAW ADMINISTRATION AND INFANT MORTALITY.

To the Editors of THE LANCET.

SIRS,—It is needless in a medical journal to discuss the amount or dangers of high infant mortality but I should like to mention one of the causes and also point out how that cause is likely to increase and how it may be diminished. Dr. A. Newsholme in his well-known work *on "Vital Statistics" says that one of the causes is the omission on the* part of the parents to call in medical aid soon enough. Mr. A. E. *Harris*, the medical officer of health of Islington, in a recent report attributed many of the deaths *from* measles to the same cause. Recently, in an Oxfordshire village a large number *of children had* diphtheria and went about in this condition and even attended school with their throats swathed up, no medical man being in attendance on them. It is needless to multiply instances and the *reason is obvious. Poor* people of the labouring class cannot afford to pay doctor's *bills or even to subscribe to clubs. If* the *baby is upset or a* child *has a sore throat* a father or widowed mother will hesitate to call in a medical man when the result will be (even on the very moderate terms on which medical men attend poor people) that the family have to go without dinner for several days. But it will be said that the Poor-law provides a medical man for the poorest. Yes, so it does; but *unfortunately there are a "hard school" of so called Poor-law reformers.* These *people* [illegible] "medical relief" has largely diminished and I think *it is practically* certain that this must have caused much *suffering* and *in some cases* death. I think the attention of the medical profession and of the Local Government Board should be drawn to this subject.

I am, Sirs, yours faithfully,

Oxford, Dec. 3rd, 1903. J. THEODORE DODD.

THE JOHN JAMES JONES SANATORIUMS.

FROM a paragraph in a recent newspaper it would seem that the Gainsborough board of guardians have not been much edified by the treat- [illegible] woman who had been sent by [illegible] *sanatoriums at Sandgate* [illegible] the board went to Sandgate and found that the [illegible] nall bedroom with three other persons and was fed with food of a second-class quality. He also found, as all readers of THE LANCET could have warned him that he would, that at these homes there was no "open-air treatment" whatever in the medical or technical sense of the word. The patients just had the use of the open air of the streets. The relieving officer appears also to have reported that in the sanatorium the sheets and the table-cloths were interchangeable. Communications have recently been forwarded to us showing that a medical man named Gore has taken upon himself the highly responsible title of medical officer to these sanatoriums. We think that Mr. Gore's position in the matter must be looked into by the General Medical Council.

PICTURE POST-CARDS AND THE HOSPITALS.

To the Editors of THE LANCET.

SIRS,—I do not see why the hospitals should not *participate* in the [illegible] from the rage for picture postcards and I there- [illegible] use of these designs, and that on each card underneath the picture [illegible] "Received from ..." and then [illegible] ed a minimum sum for each card, say 3*d*., which would pay for the cost of the postage stamp ½*d*., the cost of the postcard, and leave a margin to the hospital. The *hospital could reckon the card as 1d.* (although it would not cost that to produce) and thus the contribution would be 1½*d*. Before leaving the hospital the postcard might, if necessary, be stamped with a distinctive die to ensure authenticity. Each card of the hospital series should be numbered, say, "Guy's No. 1," "Guy's No. 2," and so on, so that any collector of picture postcards would be able to get *any particular one* of the series he wished for. If this should be thought to entail too much work at the hospitals perhaps King Edward's Hospital Fund could take charge of the issue of the different series of postcards for some of the hospitals and thus centralise the clerical work. As to whether dealers should be supplied would be a moot question, but if they were it seems to me that they should be supplied at *3d* per card less equitable amount for the cost of distribution and their profit, and even then the postcards should only be supplied to dealers taking large numbers. I do not suppose that the cost of the photographic reproductions would be very costly to the hospitals as there are sure to be some philanthropic photographers who would prepare the necessary plates for little or no charge if allowed to print their names and perhaps a word or two on the cards.

I am, Sirs, yours faithfully,

London, Dec. 1st, 1903. A WELL WISHER OF THE HOSPITALS.

THE PRICE OF A BATH AT HOTELS.

To the Editors of THE LANCET.

SIRS,—Your remarks in THE LANCET of Oct. 3rd, p. 968, on this subject are particularly gratifying to an Australian. In the grandest hotel in Australia and the poorest bush public-house if they have the water you can have a bath *free*. They are very far behind in this matter in the old country. My income is very small and when I found in an hotel in Edinburgh I had 14*s*. a week to pay for washing myself I had to leave, and then there was no shower or hot water laid on. I went to a large boarding-house in London which suited me in every thing but one—no bath-room. The charming landlady assured me the thing was already in hand and would be completed in a fortnight. I stayed there six months and the same tale continues to be told to any newcomer who happens to have clean habits. Out of about 40 people, mostly women, I found no advocates for the daily bath. It is one of the greatest discomforts we have to put up with visiting England and may your remarks have some effect on those catering for strangers, more particularly colonials.—I am, Sirs, yours faithfully,

Oct. 3rd, 1903. M. M. IRVING.

THE VAGINAL DOUCHE.

To the Editors of THE LANCET.

SIRS,—Referring to Dr. G. Crichton's letter in THE LANCET of Nov. 28th, p. 1547, he is in error in stating that the central opening at the end of vaginal tubes is a fault common to all such syringes. Speaking for ourselves, we can state that we have never sold such a tube during the past 24 years and we believe that the same answer could be given by other surgical instrument houses of repute. We know the fault does exist in some syringes on the market and equally serious defects in similar instruments when not obtained from reliable sources, but we think a general statement of this nature should only be made after full inquiry. We are, Sirs, yours faithfully,

DOWN BROS., Ltd.

St. Thomas's-street, London, S.E., Dec. 2nd, 1903.

PSEUDO (?) ANGINA PECTORIS OCCURRING IN CASES OF MITRAL STENOSIS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 21st, p. 1431, records are given of pseudo (?) angina pectoris occurring in cases of mitral stenosis under the care of Dr. Graham Steell. Dr. H. Waldo recently kindly drew my attention to a well-marked case in one of his wards, but it is not upon that case that I have any right or desire to comment. The point which it has occurred to me may have escaped the notice of some is the occasional presence of well marked fibrosis of the cardiac muscle in cases of mitral stenosis. The patches of fibrous tissue may reach the size of the nail of the little finger, not a large size, but sufficiently large to be very definite. I regret to say that I have not examined the clinical histories of the cases in which this fibrosis has been present in order to ascertain whether there had been any cardiac pain during life, but the absence of pain would not materially detract from the interest of the occasional association of fibrosis of the cardiac muscle with mitral stenosis, because it is only in the minority of any cases of such fibrosis that marked pain occurs. Although, however, severe cardiac pain is much less common than fibroid disease of the cardiac muscle, in fatal cases of angina pectoris fibrosis of the cardiac muscle is almost invariably present. The occurrence, therefore, of fibroid disease of the cardiac muscle in some cases of mitral stenosis suggests that the pathology of cardiac pain, when it occurs in this variety of valvular disease, does not materially differ from that of the pain present in cases in which valvular disease is absent. The same remark applies to aortic valvular disease, in which disease fibroid degeneration of the myocardium is common.

I am, Sirs, yours faithfully,

Clifton, Bristol, Dec. 3rd, 1903. THEODORE FISHER.

PATENT MEDICINES.

To the Editors of THE LANCET.

SIRS,—I venture to think that Dr. R. Hutchison has omitted reference to one very important factor in his very interesting paper on Patent Medicines, published in THE LANCET of Nov. 28th, p. 1492, and that is the power of suggestion.

It is useless to deny that these extensively boomed remedies do good in a large number of cases, otherwise their proprietors would not flourish as exceedingly as they do, and neither can it be denied that the improvement or cure obtained in many cases assuredly cannot be the direct result of the particular preparation that has been swallowed. I believe, therefore, that a large percentage of these widely advertised nostrums owe their success entirely to the influence of suggestion and that it does not signify a row of pins how inept or inert their composition may be provided that the ailment and the patient be sufficiently "suggestible"

Of course, it does not matter a jot to the sick man whether he is restored to health by suggestion or by drugs—he simply wants to get well—and I doubt if there is much potential of harm intrinsically in the multitude of "pills" and "powders" and "tonics," &c, th quacking advertisements of which do their suggestive work for good or for ill without ceasing; indeed, probably greater harm is done by the amateur but well-meaning prescriber who dispenses potent drugs ignorantly.

It seems to me that the only way to get rid of the pest that infests the columns of the daily and weekly press (not wholly to their disadvantage) is by the better education of the public and the greater recognition on our own part of the mental factor in the treatment of disease by drugs. Surely it is time to have done with such unscientific methods as the giving of placebos and the happy-go-lucky prescribing of drugs in various neurasthenic states of which the general practitioner sees so much nowadays. The olden time practitioner was content with his stock-in-trade treatment by medicine, and medicine, and always medicine—possibly "Little Mary" was a more troublesome child then. In these more enlightened times drugging as a method of treatment is taking a less and less important place and the tendency is to supplant, to supplement, or to obscure it by other therapeutic methods, such as electricity, hydropathy, massage, rest, &c. Might we not take a leaf out of the *quack's book and employ suggestion after a scientific method both in* the waking as well as in the hypnotic condition?

I am, Sirs, yours faithfully,

Brighton, Dec. 1st, 1903. STANLEY NOBLE.

◆

L.R.C.P.I.—We observe that the extract from the newspaper speaks of one gentleman and that our correspondent's letter speaks of another with a similar name, and we presume that the same individual is meant. We do not consider that there is any proof of "self-advertisement," as our correspondent styles the paragraph. It is our experience that such paragraphs are generally supplied to the lay press by well-meaning friends. It must not be assumed that they are sent by the medical man mentioned in them, to whom they bring considerable annoyance sometimes.

Nemo.—The person is the usual quack, the whole game of whose existence is to deceive the public.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especi[illegible] ence of local events having [illegible] desirable to bring under [illegible] be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid *to London or to local* newsagents (with none of whom have the Proprietors any connexion whatever) *do not* reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "*London and Westminster Bank, Westminster Branch*") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so [illegible] extra postage. [illegible] opies direct from [illegible] tes, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

ON

THE MODERN TREATMENT OF FRACTURES OF THE CLAVICLE, WRIST, AND ANKLE; DISLOCATIONS OF THE SHOULDER, ELBOW, AND THE SEMILUNAR CARTILAGES OF THE KNEE-JOINT.

Delivered before the South-West London Medical Society on Nov. 11th, 1903,

BY F. F. BURGHARD, M.S.LOND., F.R.C.S.ENG.,
SURGEON TO KING'S COLLEGE HOSPITAL AND TO THE CHILDREN'S HOSPITAL, PADDINGTON GREEN.

MR PRESIDENT AND GENTLEMEN,—The title of my address is of Dr. Mackintosh's choosing. If I may say so I think that his choice is a happy one, for, while the injuries included in it are among the commonest surgical affections that you are called upon to deal with, their proper treatment is still sufficiently far from being definitely decided that it is a good thing to review our knowledge by the light of the improvements that have recently been introduced into this region of surgery.

Until quite recently the ge[illegible] treatment of a fracture had [illegible] turies. Controversies certain[illegible] these were mainly about splints or other points of mere detail and not over general principles. Recently, however, it has become obvious that the old doctrine that absolute immobility is essential in a fractured limb until union is complete is no longer tenable. Formerly the surgeon's sole aim was to keep the fractured bone rigid, leaving the soft parts to take care of themselves; now his aim is to see that the soft parts are ready to resume their functions immediately union is complete taking due precautions in the meantime to prevent undue disturbance of the fractured ends. This is a most important fundamental change in the treatment of fractures and I call special attention to it before speaking of the treatment of individual fractures because it applies to fractures and dislocations in general and not to any special form; it is no doubt more essential in some forms than in others, but in all it is necessary if the best results are to be obtained. The practical results of this change in treatment are very substantial. Stiffness, pain, adhesions, and swollen limbs are no longer looked upon as inevitable when the sufferer from a fracture first begins to use the affected limb and a patient thus afflicted is apt to cast up against his medical attendant the fact that friends similarly injured but treated on more modern lines have escaped these drawbacks. Even out-patients at the hospital not infrequently require to be told "whether the splints have not been kept on too long" whenever they do not get well as quickly as they think they should. There is no doubt that better results can be obtained in the majority of cases by using the more modern methods, chief among which may be mentioned the use of the x rays, the employment of general anæsthesia, and the free use of massage and passive movements from an early period [illegible]

[illegible] greatly simplified diagnosis and [illegible] time before the diagnosis of almost any fracture in the body will be made by their help as a routine matter. In all cases in which any doubt arises in the surgeon's mind it is incumbent upon him to use this method if the apparatus be available and blame will certainly fall upon him should it turn out that an error of diagnosis has been committed when the matter might have been cleared up thereby in the first instance. All who have to deal with fractures must know how difficult it is to diagnose the existence of a fracture into a joint in the first place, and, in the second place, to say precisely the nature of the particular lesion. It is here that the application of the x rays to surgery finds one of its most important uses; it localises and defines exactly the direction and extent of the fracture, it makes clear the displacement, and it may still further aid the surgeon during the actual process of setting the fracture. Whilst, however, one can say much in favour of this potent aid to diagnosis and treatment, it is necessary to say a word in disparag[illegible] me to be consulted by patients [illegible] for malpraxis against their m[illegible] that he has set a fracture incompetently, basing their contention upon the uncouth appearance presented by the fractured ends in an x-ray photograph when really the result for all practical purposes was perfect. This, however, is a point upon which we may expect the public to become more enlightened shortly. Another point of some practical importance is that greenstick fractures in very young children cannot be traced as such by x ray photography. My experience at the Children's Hospital shows that undoubted fractures may not show any sign of solution of continuity upon the fluorescent screen; nevertheless, callus is thrown out in the course of a few days in the usual way and unless splints have been applied to prevent displacement the characteristic deformity due to the fracture is seen. The explanation probably is that the bone fibres are so soft that they bend without suffering any solution of continuity.

A second respect in which treatment has improved much of recent years is the more extended use of general anæsthesia in the treatment both of fractures and of dislocations. With a few exceptions, such as fractures of the jaw and dislocations of the semilunar cartilages, an anæsthetic should always be employed in the treatment of fractures and dislocations at the present day. It quiets spasm, it stops pain, it allows full muscular relaxation and thereby facilitates accurate coaptation, while, more important still, it keeps the patient quiet until the splints have been applied. Even though the surgeon be single handed it is well to use an anæsthetic; as soon as full anæsthesia is induced the administration can be stopped and the fracture or dislocation can then be reduced with ease before the patient comes round.

The most important improvement, however, that has been introduced into the treatment of fractures and dislocations in recent years is the use of massage and early passive movements. It used to be taught that movement of any kind delayed the union of a fracture, although a little consideration of the behaviour of a fracture of the ribs or the jaw in the human subject and the majority of fractures in animals is sufficient to disprove this view. The process by which this method reached its present status has been one of gradual development When massage was introduced into general surgery it was found very valuable for the stiffness and œdema so often met with when a patient who had been the subject of a fracture began to get about. The combination of this massage with passive movement was so successful in the treatment of these ill-results of a fracture that they gradually began to be used earlier and earlier in order to obviate their occurrence, until in recent times they have been commenced in the very earliest stages—that is, from the receipt of the injury. French surgeons use this method largely to the exclusion of treatment by splints; in many of their cases splints are dispensed with altogether and massage and passive movements are relied upon entirely from the first. The best results will probably be obtained by combining the two methods and by keeping the seat of fracture immoveable by the use of splints, while the mobility of the soft parts is assured by the use of massage and passive movement from the very first.

The rationale of the method is quite clear upon a little consideration. In any fracture there are two distinct lesions produced besides the solution of continuity in the bone itself; on the one hand, there is a tearing of the muscular or tendinous structures in the vicinity of the fracture; on the other hand, there is extravasation of blood due to the injury of the vessels. Both these lesions require attention; the effused blood can best be limited and its absorption hastened by the use of massage, begun from the very beginning. Massage, however, is not sufficient for the treatment of the torn muscular or tendinous structures; the tendency of these structures to become adherent to the seat of fracture, to one another, or to their tendon sheaths must be counteracted by passive movement begun quite early—so early, that is to say, that adhesions are either non-existent or are quite supple and plastic. It may be taken for granted that the slight vibratory movements imparted to the seat of fracture by the performance of these passive movements are in no way detrimental to the union, and it must therefore be obvious how much superior this method is likely to be to the older plan of prolonged immobility, not only of the fractured ends, but also of the soft parts and the joints in the vicinity. Another very important function, both of the massage and the passive movements, is to prevent the muscles wasting, so that the patient begins to get about, when union of the fracture is complete, with a much more vigorous limb than he would be likely to have otherwise. An obvious objection to this method is that it is not very easy to learn and that it generally requires to be carried out by the medical man himself, who can ill afford the necessary time it requires, or else by a skilled masseur whose fees are proportionately high. Granting this, however, much may be done by the medical man himself and the rest can be taught to any really intelligent person.

A regular routine should be adopted in all cases of fracture. In the first instance perfect coaptation should be made under an anæsthetic and some form of retentive apparatus applied in such a manner that it leaves the seat of fracture either exposed or else accessible without disturbing the fractured ends. The apparatus should fix the joint above and the joint below the fracture, but not those beyond, such as the fingers or the toes, as passive movement has to be begun in them at once. If there be no muscular spasm the limb may be left undisturbed until the following day. Smooth rubbing over the area of the fracture is very useful in allaying spasm and in promoting the patient's comfort and therefore, when spasm is present, the part should be gently rubbed after the fracture has been set and the limb fixed upon the splint. The rubbing should be done by grasping as much of the circumference of the limb as possible in the palm of the hand and rubbing it upwards as smoothly, gently, and evenly as possible. This rubbing is repeated on the following day for ten minutes or a quarter of an hour or so and again on the next day; it it be done quite gently and smoothly it soothes the patient in a remarkable manner. On the third day the rubbing is followed directly by that is to say, of the fingers in the case of a fracture of the passive movement of the smaller joints beyond the fracture—forearm or of the toes in a fracture of the leg. This combined massage and passive movement of the smaller joints is persisted in for the next two or three days, at the end of which another addition is made to the treatment—namely, the joint below the fracture is very cautiously moved. Passive movement of the joint above may be left with advantage to a somewhat later date. Thus the sequence of events is something like this: for the first two or three days simple rubbing over the area of the fracture alone; then from the third to the sixth or the seventh day massage is followed by passive movements of the toes or fingers, as the case may be, while to this are added from the end of the first week onwards movements of the wrist or ankle; lastly, the knee or the elbow may be moved after the end of the third week. The limb need not be disturbed in any way for the movements of the fingers or toes; when, however, the wrist or ankle has to be dealt with the limb must to some extent be taken down and allowed to rest flat upon the splint whilst one hand grasps the region of the fracture firmly and the other cautiously moves the joint. Grasping the region of the fracture in this way keeps the ends of the bones in proper position and no fear need be entertained of endangering the union in any way. When it comes to moving the knee the limb must be taken off the splint entirely and it is well in this case to support and to steady the fracture by some sort of moulded apparatus surrounding it.

At first the massage and passive movements should be practised only once a day and for a few minutes only at a time. They may be, however, gradually increased with advantage both in range and in duration until, finally, they occupy half an hour or more twice daily. In the third week the fracture will be sufficiently consolidated to be taken off the splint—surrounded at first by the moulded splint referred to above if the fracture be in the leg—and can then be turned first on one side and then on the other so as to allow all the muscles of the part to receive due attention from the masseur. After the end of the third week the union will be so far advanced that splints may be entirely dispensed with, or at the most a light casing may be applied in the neighbourhood of the fracture to support the parts, and this casing should be removed whenever the massage is applied. After a fracture treated in this manner the patient will be able to use the limb soon after the third week if it be in the upper extremity, whilst if it be in the lower extremity he will be able to walk about firmly and usefully as soon as consolidation has so far advanced as to allow the weight of the body to be supported upon it; this will be after the end of the fifth week.

In the case of dislocations also the present-day treatment shows considerable advance upon that in use a short time ago. The old plan was to immobilise the limb for a considerable time after reduction of the dislocation in order to allow the torn ligaments to unite and so to retain the joint surfaces in proper apposition. A little reflection will show that this view is not correct, since the real factor in keeping the joint surfaces in apposition is not so much the capsule, which after all is only a weak structure, but the muscles surrounding the joint. If the joint be kept immobile long enough for the rupture in the capsule and ligaments to unite so firmly as to prevent recurrence of the dislocation two serious troubles will ensue. In the first place there will be considerable adhesions in the joint, not only between the torn ends of the capsule and the articular ends but between the articular surfaces themselves. The other and more serious accident is the wasting of the muscles surrounding the joint entailed by the immobilisation. The muscles waste and become feeble through disuse and when the patient attempts to use the limb after the apparatus is taken off the muscles are powerless to ward off the various shocks that the joint must receive and the liability to recurrence of dislocation is greatly increased. If, however, instead of immobilising the limb early passive movement, massage, and even active movements be employed, nothing but good is likely to accrue. In the first place the muscles will not waste; in the second place adhesions will not form; whilst, finally, there is little liability to recurrence of the dislocation, at any rate so long as the patient does not attempt to move the joint in the particular direction in which the dislocation occurred. Everyone will realise the difficulties met with in a dislocation of the shoulder in an elderly subject treated by immobilisation The treatment of this particular dislocation will be specially referred to later.

After these few preliminary words concerning the more modern treatment of fractures and dislocations in general I will try to describe as briefly as possible the appropriate treatment of various forms of fractures commonly met with.

FRACTURES OF THE CLAVICLE.

These common fractures, although usually satisfactory in their ultimate results, often give much trouble during the early days after the injury, and the method of treatment which is still in common use—viz., Sayre's method—does not meet these difficulties in the most satisfactory way. The plan which I have adopted and which I have found to be much more satisfactory is a combination of massage with the old method known as the "handkerchief" method. In this two handkerchiefs are folded around a roll of cotton-wool until they are about the thickness of a perineal strap and these are looped around each shoulder so that the handkerchief passes over the point of the shoulder and beneath the axilla. A firm pad about the size of the closed fist is fastened in the axilla on the affected side in order to lever out the head of the bone and the handkerchiefs are then knotted or sewn together in the middle line behind the shoulders after firm traction has been made upon them, care being taken to see that the handkerchief on the affected side does not pass over the region of the fracture. This is really a form of figure-of-eight bandage and pulls the shoulders well back in a very efficacious and simple manner. A large elbow sling is next put on and gentle, smooth massage is made over the seat of the fracture from the neck downwards to the point of the shoulder. The massage should last five or ten minutes in the first instance and should be repeated twice daily for the first few days. When the patient is erect no other apparatus is necessary; when he is recumbent it is well to pass another handkerchief transversely round the trunk to fix the affected arm lightly to the side. It will be found that this method causes very little pain and spasm; the rubbing relieves the spasm almost directly and the forcible pulling back of the shoulders prevents the irritation caused by the fractured ends pressing backwards upon the structures of the neck In three or four days' time the patient may dispense with the sling at times and should be encourged to practise underhand movements, the forearm being put back in the sling from time to time. The massage is used for a week or ten days, gradually increasing in frequency and duration, and at the end of that time the patient can generally dispense with all restraining apparatus, except possibly a wrist sling in which he rests the fore-arm for a short period. Overhand movements should be attempted at the end of a fortnight and gradually increased in range and direction.

COLLES'S FRACTURE.

This, which is one of the commonest fractures met with in practice, is also one that gives rise to more anxiety than many others. The trouble may sometimes arise in setting the fracture but in the majority of cases the important point is the disability which the patient suffers afterwards from the stiffness about the wrist and the fingers and it is in this particular fracture that the modern plan of passive movement and massage produces its most brilliant results. As an example I may quote two cases that came before me only to-day in the out-patient room. The first patient, a burly mechanic, came to ask if his wrist had been broken, as he had been told that it had been. He had fallen on the outstretched palm eight weeks before he presented himself. Examination showed the typical deformity of a bad Colles's fracture and an x-ray photograph showed a fracture in the usual situation extending into the wrist-joint. The patient had the most perfect movement both in his fingers and in the wrist-joint and he declared that he had never had any medical treatment at all and that all he had done himself was to work his wrist about and to rub it; he said that he was unable to afford the time to lie up and had to go on with his work which he had done from the time of the injury uninterruptedly. He said that he had a good deal of pain on the first day but that subsided readily when he rubbed it and from the time of the accident to the time that he presented himself at the out-patient department he had never worn any apparatus of any kind, not even a sling. The other patient complained of stiffness of the fingers; he also had sustained a Colles's fracture which had been treated immediately and had been excellently reduced, but the splints applied had extended to the tips of the fingers and had been kept on for six weeks. The result was that there were adhesions in all the tendon sheaths and apparently extensive adhesions in the wrist-joint itself. The first case I have mentioned emphasises the point that is being more recognised every day—viz., that the disability after a Colles's fracture depends not upon irregularity of the fractured surfaces or upon bad coaptation so much as upon adhesions in and around the wrist-joint—mainly in the tendon sheaths surrounding the joint—and the same case shows how, in spite of very marked deformity, the use of the hand and the wrist can be perfectly preserved by the painstaking application of massage and passive movement

A safe way of treating this form of fracture is to set the bone as accurately as possible after having reduced any impaction present, preferably under an anæsthetic. An anæsthetic is not absolutely necessary in these cases but is always advisable, as, owing to the proximity of the wrist-joint, perfect coaptation is important. After reduction has once been properly effected there is little tendency for the recurrence of the displacement, as the fractured surfaces are quite broad and not easily displaced from one another. As to splints, the form in common use known as Carr's is perhaps the most comfortable, but straight anterior and posterior splints do equally well provided that the former does not reach lower down than the transverse crease of the palm. Massage over the seat of the fracture applied to the dorsal aspect of the limb should be used from the time the limb is secured on the splint and at the same time active and passive movements of the fingers should be practised. The back splint must, of course, be removed to allow of the massage. Before the end of the first week passive movements should be made in the wrist; at first the joint is merely extended as it lies on the splint, while the seat of the fracture is steadied by the other hand, but by the seventh day the limb may be taken right off the splint, the seat of fracture grasped in one hand, and passive movements of the wrist made with the other. Some time during the third week it will be possible to leave off the splint altogether, the arm being carried in a sling and perhaps being supported by a good, firm leather wristlet. Active movements of the wrist joint should be encouraged from the end of the first week.

POTT'S FRACTURE.

Pott's fracture shares with Colles's fracture the distinction of being a perpetual source of anxiety to the surgeon as to the restoration of function of the limb after the fracture has consolidated. Like Colles's fracture it is pre-eminently suited for treatment by massage and early passive movement, and in it, as in Colles's fracture, the use of a splint may be reduced to a minimum. The first point in the treatment of a Pott's fracture is to reduce the outward and backward displacement of the foot, which may be very marked. Manipulation usually suffices to correct the displacement if the knee and thigh be fully flexed during the process; *this relaxes the tendo Achillis* and allows the [illegible] h. Should [illegible] cement an [illegible] reduction of the dislocation may be prevented by the interposition of some structure, such as the tibialis posticus tendon, between the two bones and then nothing will avail but an open operation by which the obstruction may be hooked out of the way. This, however, does not concern us here. Should it be deemed inadvisable to administer an anæsthetic or should the patient refuse to take one, the spasm that is opposing reduction may sometimes be sufficiently allayed by gentle massage from the heel upwards to the knee for five or ten minutes to allow reduction to be effected.

When the astragalus has been got back into position it should be kept there by some suitable form of apparatus. This is all that the apparatus need aim at doing, for the fracture of the fibula and the internal malleolus that will probably be present also are of secondary importance. Perhaps the best plan is to put the limb upon an external lateral splint with a foot-piece at right angles and to let it lie upon its outer side with the knee flexed; this has the advantage of leaving a great portion of the limb exposed so that rubbing and passive movement can easily be performed with a minimum of disarrangement of splints. A simple back splint with a foot-piece at right angles is not a useful form of apparatus as the displacement is primarily lateral and not posterior; two lateral splints will do perfectly well. Massage is begun from the first and passive movement of the toes from the second day. It is of primary importance in these cases to prevent stiffness in the ankle or pointing of the toes and hence passive movements of the ankle should be begun within three or four days of the receipt of the accident. If care be taken to prevent lateral displacement of the foot by grasping the ankle firmly in one hand, the other may be inserted beneath the heads of the metatarsal bones and made to raise the front portion of the foot. These passive movements of the toes and ankle should be persisted in for 10 to 14 days when the patient may discard his splint or at most may wear a light poroplastic or millboard splint moulded to the outer aspect of the limb. From this time onward the range and direction of the passive movements are increased and active movements are also practised, until at the end of four weeks the patient will be able to walk quite well, bearing all his weight upon the limb. In this case it will be unnecessary to devote any attention to the knee-joint.

The old plan of treating Pott's fracture was to put the limb up in a plaster of-Paris casing which was worn for from four to six weeks or even longer. The result was that adhesions made their presence manifest in the ankle-joint immediately the patient began to get about and lameness resulted. Besides this, the condition of the muscles of the leg was bad, œdema and discolouration of the extremity followed, and the time that elapsed before the patient regained perfect use of his limb—if, indeed, he ever did so—was as long as, if not longer than, the period for which the limb had been confined for the healing of the fracture. It may be said that with proper treatment a patient suffering from an ordinary uncomplicated Pott's fracture should be able to walk without pain immediately the fracture is sufficiently consolidated to bear his weight.

DISLOCATIONS OF THE HUMERUS.

The chief obstacle to reduction in any form of dislocation of the shoulder is muscular contraction which keeps the head of the bone out of place, *therefore the first thing to be done is to overcome this*. The best method of doing so without unnecessary damage to the soft parts or further laceration of the torn capsule is to administer an anæsthetic. The spasm is at once controlled and the dislocation will become reduced either spontaneously or after very little manipulation. The surgeon will generally find that if he administers an anæsthetic soon after the occurrence of the dislocation reduction has spontaneously taken place by the time the patient is fully under its influence. It is quite safe to give an anæsthetic and to reduce the dislocation single-handed, since directly the patient gets under to the surgical degree reduction can be effected in a few seconds by simple manipulation.

The important point, however, is the after-treatment. It used to be the custom to immobilise the joint for a long time in order to obtain union of the torn capsule. Experience shows that this is quite unnecessary and that union of the capsule will occur in spite of even active movements. The most important danger to be guarded against is the wasting of the muscles surrounding the joint, as this greatly increases the tendency to recurrence of the dislocation when the patient begins to use the limb again. The best plan is to employ careful smooth rubbing of the muscles about the articulation immediately after reduction, while the elbow is put into a sling and the affected arm is fastened lightly to the thorax by a suitable belt or bandage in order to prevent the patient from abducting the limb. Underhand passive movements may be practised from the second or third day and the patient should be urged to perform them for himself also. The only movement that must be guarded against is that in which the dislocation occurred—viz., abduction of the limb—and the patient must be warned against doing this for at least a fortnight after the accident. The reason for this is that if abduction be made, the weakened deltoid fails to oppose the adductor muscles which will therefore draw the head of the bone inwards towards the chest and out through the existing rent in the capsule. If this treatment be vigorously carried out the patient will be able to use the arm well in two or three weeks without any fear of the displacement recurring, a decided contrast to the feeble, useless joints so often seen after a dislocation of the shoulder treated by prolonged immobilisation, and a very marked contrast indeed to those distressingly frequent cases in elderly subjects where reduction is followed by severe adhesions and almost complete immobility of the joint.

DISLOCATIONS OF THE ELBOW.

There is little to say about dislocations of the elbow; perhaps the most important point is their correct recognition. It is not uncommon to find a dislocation either entirely overlooked or only partially reduced or confounded with a fracture. In all these cases an x-ray photograph will show the true nature of the affection at once and it is in injuries about the elbow joint that this aid to diagnosis finds perhaps its most useful expression. The dislocation should be always reduced under an anæsthetic; the old plan of forcibly flexing the joint around the knee is, although generally effectual, clumsy and painful and may give rise to lacerations of the joint structures which are better avoided. If an anæsthetic be administered, however, reduction can be effected with a minimum of trouble and damage directly the patient is under its influence.

The after-treatment presents few points of importance, the nature of the articulation being such that there is little tendency for a recurrence of the displacement. It will be sufficient to put the forearm in a sling and to practise gentle massage, followed after the second or third day by passive movements in the direction of flexion and extension, pronation and supination. Flexion and extension should not be carried too far for the first week, as otherwise the dislocation may recur, especially during forced flexion. The patient should be able to use the limb perfectly in about a fortnight after the occurrence of the injury.

DISLOCATIONS OF THE SEMILUNAR CARTILAGES OF THE KNEE-JOINT.

Although this designation is applied to a large class of cases met with in practice it is well to remember that the true cause of the mischief is not necessarily due to a displacement of a semilunar cartilage at all. Symptoms quite identical may follow nipping of the synovial membrane between the articular ends of the bones either in the subjects of chronic synovitis or even in those whose synovial membrane is apparently perfectly healthy. The semilunar cartilage may be detached from the tibia either along its convex border or at one end, or in other cases again it may be split transversely or longitudinally. Time does not allow me to go into the exact cause of the mischief but it may be roughly said that as a rule the lesion is produced by some violent rotary movement of the femur upon the tibia, the result of which is to displace the semilunar cartilage, which at the same time is considerably bruised. The symptoms are exactly similar, both in kind and often in degree, whether the cartilage be misplaced or merely bruised; there is the acute sickening pain when the structure is nipped between the bone ends, the sudden giving way of the limb, so that the patient often falls to the ground, and, as a rule, there is the characteristic "locking" of the joint in the position of semi-flexion. This phenomenon may not always be present, but it is worth while remembering that it may be met with in the bruising of the synovial membrane as well as displacements of the semilunar cartilage. After the patient has straightened the limb or has had it straightened for him an interval elapses, at the end of which acute synovitis with effusion takes place; this lasts for a certain length of time when it gradually clears up and the patient is able to get about, sometimes with an apparently sound knee and at others with a tender or aching spot. As a rule the accident is repeated after a short time; it may have all its former intensity, it may even be worse, while in some cases it may never recur at all. Each succeeding attack leaves the capsule of the joint weaker and weaker and also leads to increasing atrophy of the thigh muscles owing to the prolonged and repeated immobilisations of the joint necessitated by the recurrent attacks of synovitis. Finally, the patient becomes disgusted with this semi-invalid condition and the knee-joint is opened and the semilunar cartilage or the enlarged synovial fringes are removed.

The treatment of dislocation of the semilunar cartilage has been developed considerably in recent years and, although the more purely surgical treatment—viz., the excision of the semilunar cartilage—has *pari passu* been brought to a high pitch of perfection, nevertheless it is probable that in the near future we shall see these operations less often done than is the case at present and more cases permanently cured by less radical measures. The most important point, if the surgeon sees the case at the very outset, is to replace the cartilage should this have been dislocated. This is done by still further flexing the already semi-flexed knee, placing one finger or thumb firmly over the region of the protruding cartilage, pressing the latter back, and at the same time vigorously extending the knee. This usually allows the cartilage to slip in with a distinct snap when the knee is easily extended and can be moved fairly easily. It is important to remember that this cannot always be done, especially when the damaged structure is a fringe of synovial membrane and not a displaced semilunar cartilage. It will then happen that the attempts at reduction fail and the knee remains semi-flexed with a tender swelling between the bone ends. In these circumstances the best plan is to give an anæsthetic and gently to attempt reduction; it may, however, turn out that complete extension of the limb is impossible even under full anæsthesia and, if this be the case, it is very important not to persist, as reduction is probably mechanically impossible and the swelling that prevents the limb from being fully extended is a bruised synovial membrane into which there is effusion of blood. The limb will come straight as the swelling subsides.

The next point in the treatment is to subdue the acute synovitis that is practically certain to follow the injury to the joint. Some surgeons are in the habit of sending the patient to a gymnasium at once and of moving the limb vigorously, even during the period of acute synovial inflammation. This is, I think, wrong, and a short period should be devoted first to the treatment of the effusion into the joint. The limb should lie comfortably on a back splint and some evaporating lotion—such as spirit, lead, or lead and opium lotion—should be applied; at the same time massage of the thigh and leg muscles is practised without raising the limb from the splint. This should be done at once and persisted with until the swelling has subsided, which will probably be in the course of a week; no passive movement, however, should be adopted during this period. The massage is a most valuable auxiliary to the rest and evaporating lotions; it is primarily designed to prevent wasting of the leg and thigh muscles which is so rapid and so constant a phenomenon after the immobilisation of the joint for this injury. It also promotes absorption of the synovial effusion and it stimulates the circulation in the part, but its principal function is to prevent muscle waste and to maintain the tone of the muscles and thereby to facilitate the return of the capsule to its normal size as the effusion subsides. This important point was overlooked a few years ago when these cases were treated by prolonged immobilisation and the result was that the muscles wasted to an extreme degree, so that when the patient got about again he always had a feeling of insecurity in the joint and the ligaments and capsule were so feeble that the accident recurred on slight provocation.

Active and passive movement should be begun when the effusion has become absorbed—generally after the end of the first week—and must be persisted in for a long time. The movement should be entirely confined to flexion and extension; it is very important that no rotation of the tibia upon the femur should be allowed. The passive movements should be preceded by massage. The patient may walk about with the limb restrained by an elastic knee-cap or a bandage which will serve to remind him that the joint is unsound and he may practise gymnastic exercises in the form of flexion and extension; these should mainly take the form of pedal exercises which strengthen the muscles of the thigh and leg. Massage should also be practised daily for half an hour or more at a time and this treatment should be continued until the capsule has once more become normal and there is no wasting of the thigh muscles; it is never safe to leave it off until then.

In cases treated on these lines good results will be obtained in a large number that are seen from the first and in many no second attack will ever occur. If the original injury was *a partial displacement of the semilunar cartilage* this structure may become fixed in place again and recurrence of the accident is then guarded against by strengthening the muscles of the articulation. If, on the other hand, the case is one of bruised synovial fringes, the rest and massage will lead to the disappearance of the enlargement and a cure will result.

Cases are not infrequently met with in which either the above treatment does not succeed in preventing subsequent trouble or in which the patient only comes under notice after the condition is well established and there have been several previous attacks. In these circumstances the question if anything short of operative treatment can be done will have to be decided and the applicability of apparatus must arise. It may be said here at once that no form of apparatus is any real good. The various forms of knee trusses are of no value whatever; the pad that is supposed to press back the semilunar cartilage is quite useless, for the cartilage as a rule is not in any need of being pressed back, seeing that it is separated from the head of the tibia and probably lies loose somewhere between the articular ends The only form of apparatus of any use whatever is one designed to prevent lateral bending of the knee, which is in itself a potent factor in allowing displacement of the cartilage, but apparatus of this kind should only be used when, for instance, the patient refuses operation or when it is considered inadvisable to perform one.

Concerning the operative treatment I need say little and concerning the actual steps of the operation I shall say less. The operation consists in opening the joint freely and in removing as much of the displaced cartilage as can be got at. It has been recommended to suture a displaced cartilage back into place, but it is probably better to abandon this method in favour of the simpler and more radical method of removing the offending structure The patient gets on exceedingly well without the semilunar cartilage and its removal does not affect him injuriously in any way, while if it be the real cause of the symptoms its removal prevents any chance of recurrence. A point of great practical importance, however, and one that is not sufficiently recognised *is that it may be necessary to do more than remove* the cartilage. In cases that have lasted a long time and have been the subject of several attacks of synovitis the synovial membrane becomes so hypertrophied that large fringes hang into the joint cavity, especially in the region of the ligamentum mucosum and the ligamenta alaria and get nipped between the bone ends, so that the symptoms may be reproduced even after complete removal of the cartilage. Before proceeding to close the wound, therefore, after the cartilage has been removed, careful search must be made for [illegible] the ligamentum patellæ, and [illegible] nipped off. The operation in skilled hands is safe and successful, but it must never be forgotten that it is not enough merely to open the joint and to remove the cartilage or the synovial fringes and then to consider the patient cured. Most of these cases are only submitted to operation after repeated attacks of synovitis and the capsule of the joint is in a very relaxed condition and the muscles are greatly wasted through the continual attacks of inflammation and its consequent immobilisation The patient will therefore require to be put through a regular course of massage and exercises after the operation in order that the tone of the capsule may be restored by improving the condition of the muscles surrounding the joint. The treatment, indeed, will closely approximate to that already sketched out for a case of displacement of the semilunar cartilage seen immediately after the receipt of the injury. It is very rare to get recurrence of the symptoms after the operation In the few cases in which they are known to have occurred the explanation has generally been that enlarged synovial fringes have been left behind. In some cases the real origin of the mischief has been an osteo-arthritis which has progressed in spite of the operation.

REMARKS ON 50 CONSECUTIVE CASES OF PERFORATED GASTRIC AND DUODENAL ULCER TREATED BY LAPAROTOMY.[1]

BY T. CRISP ENGLISH, M.B. LOND., F.R.C.S. ENG.,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; ASSISTANT SURGEON, GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN; SURGICAL REGISTRAR, ST. GEORGE'S HOSPITAL

THE fiftieth operation at St George's Hospital for perforation of a gastric or duodenal ulcer was performed in June of this year. Having had the opportunity of observing and taking notes of the majority of these cases during the last six years I thought that it would be interesting to review the cases as a whole, especially in regard to certain points, such as the question of premonitory symptoms, the incidence of complications, and the after-results. For permission to use the cases I am greatly indebted to the physicians and surgeons under whose care they came. Few subjects have attracted more attention during the past few years than the condition of perforated gastric or duodenal ulcer and the number of recorded cases is now very large. In a condition of this kind, the operative treatment of which is comparatively new, it is important that cases should be reported systematically and it is unfortunate that more use cannot be made of the vast amount of material available in the wards of the large general hospitals. Cases of the greatest interest are relegated to the hospital "Reports," if such are published, or more often remain in the hospital case books and are buried in oblivion. The value of hospital statistics, faithfully recorded, is obvious. *A long series of consecutive* cases, which *includes the failures as well as the successes*, the unfortunate cases as well as the surgical triumphs, cannot fail to give more accurate information than a collection of cases from the medical journals. It is notorious that the ways of human nature are such that the cases which find their way into the medical press are conspicuous by the absence of the correct proportion of failures. A series such as the present one possesses further value in that it represents the practices of many surgeons and the results of widely different methods.

In this paper, which I have the honour to read before you to-night, acute perforations of duodenal ulcers have been grouped with those of gastric ulcers, as the general aspect of the cases is very similar; on the other hand, an entirely different clinical picture results with subacute or chronic perforation and no cases of this nature are included in the series. Three cases have been admitted into hospital in which no operation was performed owing to the condition of the patient being too desperate for surgical interference; and in two instances patients were brought in dead, death having speedily occurred during the initial shock. In these latter cases the rent in the stomach wall was large and the peritoneal cavity was flooded with material from the stomach. In these 50 consecutive cases the stomach was the seat of [illegible] In [illegible] ales, [illegible] with [illegible] this series, however, in which liver dulness was noted as absent before operation, the colon was found in front of, and considerably compressing, the right lobe of the liver.

---

[1] A paper read before the Royal Medical and Chirurgical Society on Nov. 24th, 1903.

It has been stated that the presence of a well-marked area of stomach resonance in the left hypochondrium contraindicates perforation of the stomach. It was, however, frequently noted during the operation that the stomach was distended with gas and sometimes greatly distended when the perforation was small or valvular. The extent of gastric resonance is therefore of no diagnostic value. I may here mention that in two cases seen shortly after perforation I was struck by the fact that sweating, though present over other parts, was more intense by far over the epigastrium.

The situation of the perforation is shown in the accompanying diagram. During operation it is often very difficult to be certain as to the exact position of the ulcer, more especially when there are many adhesions or much lymph around, and discrepancies upon this point are frequently found in the accounts of the operations and the post-mortem reports. The diagram shows that perforations most commonly take place in ulcers situated close to the lesser curvature and are rather more frequent towards the cardiac than the pyloric end of the stomach. On the other hand perforating ulcers close to the greater curvature are comparatively rare. Five of the ulcers occurred on the posterior wall, close to the pylorus; the rents were usually large and the gastric contents had escaped through the foramen of Winslow into the greater sac of the peritoneum. The duodenal perforations all occurred in the first part of the duodenum, six on the anterior wall and two on the upper and posterior wall.

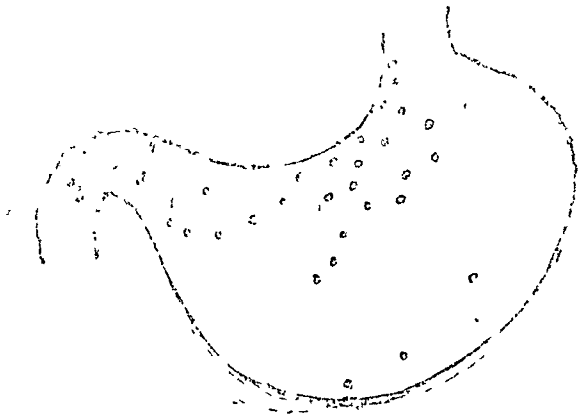

Diagram showing the situation of ulcers on the anterior wall of the stomach and the duodenum.

The number of instances in which perforated duodenal ulcers have been successfully sutured is still so small that details of two cases in this series may here be referred to. The first case has already been mentioned as an example of the "latent period" or period of repose; it has been published in detail elsewhere.[2] The second case occurred in a female, aged 22 years, with a history of old but not recent indigestion. Eight hours after taking some aperient pills she was suddenly seized with agonising pain, felt at first in the right hypochondrium and later spreading over the entire abdomen. She felt sick but no vomiting occurred. The pain continued and morphia was given; the bowels acted scantily after an enema on the third day, when she was admitted into hospital. Her condition was then masked by morphia; pain was referred vaguely to the right side; the abdomen was hard, rigid, and tympanitic all over, immobile, but not much distended; liver dulness was diminished. Laparotomy was performed about 68 hours after the onset of symptoms and free gas with foodstuff was found in the peritoneal cavity. A small perforation in the first part of the duodenum was discovered and occluded by a purse-string suture, strengthened by four Lembert stitches. The peritoneum was thoroughly irrigated and she was discharged four weeks later after an uneventful convalescence.

The possibility of saving the patient's life even in the most desperate cases is further illustrated by a case in which a perforated gastric ulcer was successfully treated 72 hours after the onset of symptoms. The case is a remarkable one for there was intense general peritonitis and the patient's condition before operation was so precarious that surgical interference seemed scarcely justifiable.

The incidence of complications arising after operation will next be discussed. Of the 24 cases in which the patients recovered definite complications occurred after operation in 13, whilst in the fatal cases in which the patients survived the first 24 hours after operation complications developed in eight. In the two cases in which perforated duodenal ulcers were successfully sutured the patients recovered without complications; empyema was present in one of the fatal cases. It appears that in more than half of the successful cases complications may be expected during the period of convalescence, and, further, that complications are often multiple and are more commonly noticed after than during the first week.

TABLE III.—*Incidence of Complications.*

	Non-fatal cases.	Fatal cases.
Parotitis	4	1
Pleurisy, plastic or serous	6	9
Empyema	—	2
Pneumonia	1	2
Pulmonary abscess	—	1
Thrombosis	3	—
Hæmatemesis	1	2
Hæmorrhage from another ulcer	—	1
Nephritis	1	—

Inflammation of the parotid gland occurred in five cases, being bilateral in two and involving the gland on the left side in the other three. It was first noticed on the second, third, fifth, sixth, and sixteenth days respectively and in the bilateral cases the onset of inflammation on the two sides was separated by an interval of two days. Suppuration—a very unusual event in these cases—occurred in both glands in the first case operated upon at St. George's Hospital; the right parotid had become inflamed on the second day and the left on the fourth day, and pus was discharged from both ears on the ninth day. Incisions were made and the resulting sinuses persisted until death six weeks later.

No definite relation to the absence of feeding by the mouth is noticed, three of the patients in whom this complication occurred having had food by the mouth for more than 24 hours. Mr. B. N. Tebbs, of St. George's Hospital, has very kindly given me figures relating to the incidence of non-specific parotitis. Of 32 cases occurring in this hospital during the last ten years 21 followed operation upon, or disease of, the stomach.

Total	21

Pleurisy is by far the commonest complication, occurring in six of the successful cases and being found in 11 of the 21 cases in which the chest was examined post mortem. As would be expected, the left side was most commonly involved; the actual figures are—both sides, five cases; left side, ten cases; right side, two cases. The pleurisy was usually of the dry fibrinous variety (11 cases) and limited to the diaphragmatic area. In two fatal cases, however, an empyema was present. It seems probable that the pleurisy is often due to the transmission of toxic products through the diaphragm and not to the presence of micro-organisms, for the effused fluid is usually sterile and empyema is uncommon. This is illustrated by a case which occurred two years ago.

CASE 6.—The patient was a female, aged 23 years. On the fifth day after operation friction was heard in the left lower axillary region; this was followed by signs of effusion into the pleural cavity and on the eleventh day the pleura was aspirated and 21 ounces of serous fluid were withdrawn. Microscopically this was found to contain a very large number of highly active leucocytes, whilst cultures made from the fluid proved absolutely sterile. The temperature remained high and irregular and rigors occurred. An empyema was suspected and the pleural cavity was opened in the mid-axillary line on the sixteenth day. Only clear fluid, however, was found and so the diaphragm was punctured. *This led to the discovery of a large sub-diaphragmatic abscess* containing a quantity of very foul pus.

---

[2] THE LANCET, March 29th, 1902, p. 890.

Amongst the other complications are the following. Thrombosis occurred in three cases, the left external saphena vein being involved twice, and the deep veins of the left leg in the other case; the symptom was first noticed on the fourteenth, sixteenth, and seventeenth days respectively. Severe hæmatemesis occurred in three cases, two of which ended fatally; death in one case was due to blood inhalation during vomiting, the trachea and bronchi being found full of blood post mortem. Reference has already been made to a case in which severe hæmorrhage from perforation of the *gastro duodenal artery* by a duodenal ulcer proved fatal 11 days after successful suture of a perforated gastric ulcer. Hæmaturia and albuminuria were noticed on the seventh day in a female, aged 28 years, although as far as could be ascertained this condition had not existed before. Albumin and renal casts with a few pus cells were present in the urine *for six weeks*, at the end of which time the urine became normal.

All the symptoms and physical signs of perforation may be presented and yet the stomach may be found intact when the abdomen is opened. Such cases must occur in the practice of any hospital or of any surgeon of experience, for undoubtedly the correct treatment *is to explore whenever perforation is suspected* A small incision above the umbilicus will at once decide the question and involves practically no risk in itself, whilst a few hours of delay may be sufficient to make operation futile. These cases may be divided into two classes—those in which some other peritoneal lesion is found and those in which nothing abnormal is discovered. I have the notes of seven such cases. All the cases occurred in young females with histories of gastric trouble; the symptoms and signs pointed to perforation of the stomach and operation proved that this had not occurred. In three cases no abnormality of any kind was discovered; one case was especially interesting as she was admitted at exactly the same time as another patient with exactly identical symptoms, which proved in the latter case to be due to a perforated gastric ulcer. Another patient, a highly neurotic woman, aged 28 years, who had already had laparotomy performed twice, was admitted in the middle of the night with acute abdominal symptoms. In the fourth case nothing was discovered beyond some blood-stained œdema of the gastric attachment of the omentum. In the fifth case the peritoneal cavity contained blood-stained fluid; the pelvis was examined *through a second incision and apparently* rupture of a small ovarian cyst was the cause of the condition The sixth and seventh cases proved fatal. In one the abdomen was full of odourless turbid serum and a most careful search failed to reveal the source of the infection; the stomach was most certainly intact; no necropsy was performed. The other was a case of acute appendicitis with general peritonitis in a young dyspeptic girl in whom all the physical signs were most intense in the epigastric region. The reverse *condition, of course, is more common—namely, the simulation of appendicitis by a perforation of the pyloric* end of the stomach or duodenum, owing to the downward gush of fluid, and in four cases in this series the primary incision was made over the region of the appendix. It is interesting to note that in two of the three cases in which there was no intra-abdominal lesion the symptoms occurred shortly before the onset of the menstrual period. I have seen several other cases in which neurotic women have presented acute *abdominal symptoms at this time; the clinical* picture of perforated gastric ulcer may be closely simulated, but, generally speaking, there are not the *severe collapse* and intense pain at the outset and constitutional disturbance is not so marked. The symptoms clear up with the onset of menstruation. It would be interesting to hear of other cases of this nature.

[illegible] ulcers are present in other parts [illegible] is well illustrated by examination of the fatal cases. In 13 of the 21 cases in which necropsies were performed other peptic ulcers were present and it is quite possible that small ulcers may have been overlooked. In two instances *four ulcers* were present in addition to the one which had perforated. Their most common situation was exactly opposite the peforated ulcer. Although no cases of double perforation occurred, in one instance a second acute ulcer of the perforating type was found to have reached the peritoneal coat of the stomach.

In regard to the details of the operations it is found that general irrigation of the peritoneal cavity was employed in 31 cases, local irrigation in nine cases, and in the remainder *sponging only was relied upon*; with each of the three methods the mortality was the same—namely, about 60 per cent. A further point brought out by a study of the cases is the *increasing tendency to dispense with drainage.* This is a question upon which surgeons differ greatly and is one well worthy of discussion. The difficulty in securely closing the perforation in deeply seated ulcers was frequently found to be diminished by the preliminary separation of adhesions to the liver and surrounding parts and by the use of cleft palate needles: the line of suture was strengthened in six cases by omental grafts or plugs and in three cases by a similar use of masses of lymph. In a case in which the perforation was deeply placed near the œsophageal opening and stitching was impossible owing to the friability of the surrounding gastric wall, strips of gauze were passed down to the ulcer; no further escape of gastric contents occurred and an uneventful recovery followed.

In conclusion reference must be made to the *after condition of the patients.* Do the symptoms of gastric ulcer recur or is the patient cured by operation? The question is one of practical importance, for certain authorities recommend that a posterior gastro enterostomy should be *performed after the perforated ulcer has been dealt with if the* patient's condition will bear it. This operation would be exceedingly difficult, or perhaps impossible, if attempted at *a later date, and so it is urged that it should be done at* once in order to complete the patient's cure. Regarding the matter from a theoretical point of view we might expect the symptoms of ulceration to recur if the perforation be simply sutured. These ulcers are known to be usually multiple and the local conditions which favour ulceration still exist. In practice we find that *this is not the case; the after-results* are surprisingly good. During the last summer I have written to each of the 24 patients in the successful cases. An investigation of this kind is always difficult, for hospital patients of all kinds, and domestic servants in particular, are constantly changing their address and so are readily lost sight of. I was able, however, to trace 17 of the 24 patients. The reports of these cases may be summarised as follows. In 11 cases there had been no return of gastric symptoms of any kind and the patients had been quite well since the operation; two had married and had had children; and in four cases dyspeptic symptoms were complained of, two being readmitted into hospital for short periods. The point which I wish to emphasise here is that the symptoms were characteristic of dyspepsia and not of gastric ulcer; the pain was of a dull, aching, diffuse character and in no case was there vomiting or hæmatemesis. One patient came under treatment one and a half years after operation for œdema and superficial varicose veins of the leg; *this case had been* complicated by thrombosis and was satisfactorily treated by an elastic stocking; there were no gastric symptoms. Another patient was recently seen seven years after operation. She was suffering from congestive dysmenorrhœa and the pelvic organs were found to be extensively matted by firm adhesions; slight peristalsis of the intestinal coils was also visible through the abdominal wall. She had been married for five years and was sterile. It seems highly probable that in this case the pelvic *peritonitis, with the* subsequent dysmenorrhœa and sterility, dated from the gastric perforation. The number of cases is small but the results point conclusively to the fact that the great majority of the patients are cured of their gastric ulcers if they survive the primary operation. Dyspeptic symptoms occur in a small proportion of cases and are readily amenable to medical treatment Gastro-enterostomy is therefore unnecessary; in any case there are many arguments against its immediate use in cases of perforation. *It materially increases the* duration of the operation and rapidity is essential if the patient is to have her best chance. In itself the operation involves an increased risk; the parts are in the worst possible condition for a complicated plastic operation; and finally, as I have said, it is unnecessary. I have already referred to a patient who died from hæmorrhage from a duodenal ulcer on the fifteenth day after suture of a ruptured gastric ulcer. In this case it is possible that a *gastro-enterostomy might* have checked the progress of the duodenal ulcer and prevented the fatal hæmorrhage; but the, case is quite an exceptional one and forms no argument for the routine performance of gastro-enterostomy.

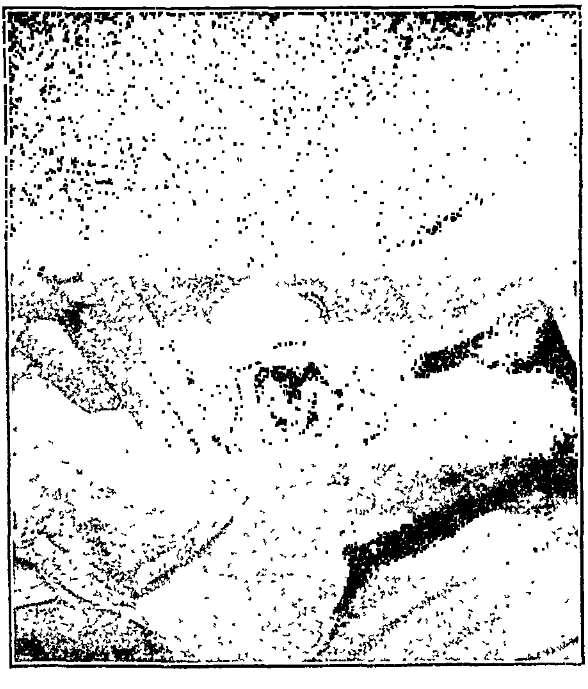
Grosvenor-street, W.

CLEFT-PALATE AND HARE-LIP; THE EARLIER OPERATION ON THE PALATE.

BY EDMUND OWEN, F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

FOR about 20 of the years that I was upon the active staff of the Hospital for Sick Children, it was my practice to operate upon hare-lip in early infancy but to postpone the treatment of the cleft-palate until the child was two, three or four years old. This plan of procedure was, indeed, a very general one. It had been adopted for several reasons—the fissured lip was dealt with before the cleft-palate because experience had shown that if the infant were in a fair state of health he could confidently be trusted to stand the shock of that lesser operation. Moreover, it was thought that if the gap in the lip were soundly closed the anterior part of the palatine cleft would keep on growing narrower up to the time of the operation on the palate. The palatine cleft was left uninterfered with because it was thought that at this tender age the infant would not be likely to survive the shock of the prolonged operation for its closure, accompanied, as it must be, by a very considerable loss of blood.

FIG. 1.



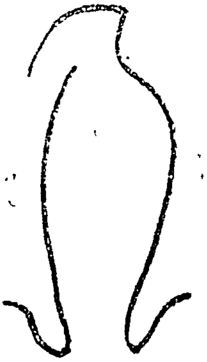
Cleft-palate and hare-lip in an infant aged three months.

A few years ago my attention was directed by my colleague at St Mary's Hospital, Mr. Morton A. Smale, to the method of treatment of cleft-palate which he had seen Dr. Brophy adopt at Chicago. Dr. Brophy not only operated upon the palate before the lip in early infancy, but he dealt with the palatine cleft in an original and very radical manner, namely, by boldly thrusting the maxillary and palate bones together in the middle line.

Since becoming more fully acquainted with Dr. Brophy's method I have cordially adopted it, and though I realise that it is not unattended with risk, still I consider the advantages associated with it are so great that the extra risk may be unhesitatingly accepted.

By way of illustrating Dr. Brophy's method, I will briefly describe it as carried out in the case of a male infant whom Dr. D. Bennie Hewat recently sent to me from Cape Town. The infant was three months old on Feb. 3rd, 1903, the day that I first saw him. He was a miserable-looking object, and he weighed but six and a half pounds. When he cried, the mouth and naso-pharynx showed as one large cavity (Fig. 1) which the maxillary processes very ineffectually attempted to separate. Indeed, for so small an infant, the cleft was enormous—which is much the same thing as saying that the horizontal processes of the maxillary and palatine bones offered but scanty material for the formation of a roof to the mouth. This is not shown in the illustration, but the width of the gap in the lip more than suggests that the palatine cleft was a wide one. Its exact width, as determined by a pair of compasses, is shown in Fig. 2. The cleft extended into the right nostril. The vomer was adherent to the left maxillary process.

FIG. 2.



Cleft of palate extending into the right nostril in an infant aged three months.

Before the operation, a warm enema of peptonised beef-tea with a little brandy was given, and the infant was swaddled in Gamgee tissue. The operating-table was made almost as high as an ordinary mantel-shelf, so that the surgeon might carry on his work without having to stoop too much. Chloroform was the anæsthetic, which Mr. Henry Davis gave on a small mask. The tongue was drawn forward by a long suture, and the mouth was kept open by a modified Smith's gag.

The operation was begun by paring the edges of the cleft, and after this I tried, but ineffectually, to thrust the maxillæ towards each other by firm pressure with the fingers and thumb. Next, following Dr. Brophy's directions, I raised the cheek, and, by a strong curved needle in a handle, passed a silk suture across the nasal fossa, above the level of the hinder part of the alveolar processes. The end of a thick silver wire was then hooked on to this suture, and, by pulling on the latter, the wire was made to take its place. The wire suture thus lay above the horizontal processes of the palate bones, where it could be seen through the cleft. Similarly, a wire suture was taken through the maxillæ above the front part of the cleft. Two small, oblong leaden plates, with a hole drilled near each end, had already been prepared, and one of them was then laid along the outside of the right maxilla, under the cheek, the end of the hinder wire being passed through the posterior hole, and the end of the front wire through the anterior hole. The right ends of the wires were then twisted together from left to right, the plate being closely applied against the maxilla, after which the twisted ends of the wires were pressed down flat. The ends of the wires under the left cheek were then similarly treated, and as they were being twisted up the maxillæ were squeezed together, or, rather, another vigorous attempt was made to squeeze them together. But I could not move them. So, in accordance with Dr. Brophy's advice, I then incised the mucous membrane over each malar process and, introducing a scalpel, divided the maxillæ sufficiently to enable me to thrust their palatine processes into the middle line. After this it was at once seen that the width of the gap in the lip was much less, and that the lateral halves of the soft palate were brought quite close together. Fine wire sutures were then passed through the freshened borders of the entire cleft.

The infant was very ill for two or three days, and the union of the sutured borders was only partial, but the front of the cleft was solidly closed, and a useful bridge held securely at the junction of the hard and soft palate. Subsequently, by the aid of three small supplementary operations, the cleft was entirely closed with the exception of a spot of the size of a rabbit shot about a quarter of the way along the line of suturing. (This I closed just before the child was about to depart on his journey home to the Cape.) On May 5th, after he had been for a visit to the seaside, I operated on the hare-lip, his weight being then 12 pounds. The present condition of the infant is shown in Fig. 3.

FIG. 3.

Appearance of the infant after operations on palate and lip.

In a letter dated Oct. 13th, 1903, Dr. Hewat sends me the report of his examination of the child on his return to Cape Town. He says that he deems the result an excellent one both as regards the palate and the lip, "very much better than I thought possible on account of the gap being so large and there being so little tissue available for the purpose of filling in."

In this particular case the cleft was so wide that when I had with difficulty approximated the anterior parts of the maxillæ I was afraid to deal with the hinder part of the cleft as thoroughly as I had intended. In ten days time, however, I did a little more, and after another ten days I vivified and sutured the sides of the soft palate and uvula the opposed borders of which were lying quite close to each other.

The essential, and at the same time the most difficult, part of Brophy's operation is the approximation of the maxillæ Brophy, however, apparently finds little trouble or difficulty with it. He says: "If we are unable to close the fissure with these wires, if from lack of time or from firm resistance of the parts it cannot be done, there is a further method to be employed which will obviate these difficulties. With your knife, after the cheek is well raised, divide the mucous membrane just over the malar process. Here insert a knife in a horizontal direction," dividing the bone freely but damaging the mucous membrane as little as possible. The lower parts of [illegible] and on again twisting up the [illegible] cleft is closed by their approximation.

A priori I should have expected that this thrusting inwards of the maxillæ would have determined the occurrence of a contracted palate. Up to the present I have been unable to inform myself on this matter, but Brophy, who speaks from ample experience, affirms that this is not so. He argues that the alveolar process develops with the eruption of the teeth, and that in due course the teeth of the upper jaw will be found antagonising those of the lower jaw "in a normal way." But should this antagonism not take place, Brophy, speaking *ex cathedrâ*, as professor of dental surgery, says that the arch can be expanded and the [illegible] did not [illegible] r jaw, it [illegible] dental surgeon to insure this taking place. But even if the arch were ultimately found comparatively small, that defect would be more than counterbalanced by the fact that, owing to the approximation of the hinder ends of the maxillary processes, the surgeon had been enabled to form a soft palate without the occurrence of tension, and without interfering in any way with the (palatine) attachments of the tensor palati, the palato-pharyngeus and the levator palati.

After operating by the old method, it is quite a common experience to find the velum as tight as a drum as soon as the sutures are inserted, and if it were so left not many hours would elapse before the edges tore themselves asunder. But of course the surgeon does not leave the adjusted velum in that condition. He relieves it of all tension either by the method of Fergusson or Pollock, or in some other way. The plan which I follow is that of making a free incision from before backwards through the entire thickness of each half of the velum near its lateral attachment. And when the cleft has been wide, the available tissue of the soft palate scanty, and the tension, therefore, considerable, it takes no little courage to make these lateral incisions sufficiently free. Subsequently, whether the line of sutures holds, or whether it breaks down, these lateral incisions gradually fill up. But inasmuch as they fill up with granulation tissue which is eventually converted into scar tissue, the muscular or aponeurotic fibres of the velum cannot escape permanent damage, which must surely have a prejudicial effect upon those delicate movements of the soft palate which make for clear articulation. To what extent this injury may be responsible for the imperfect results—so far as intonation is concerned—which sometimes follow even an entirely successful operation upon a wide palatine cleft, one cannot say. But I must regretfully admit that in some cases in which I have secured a perfect closure of a wide palatine cleft at the age, say, of three or four years, [illegible] the clearness [illegible] much to be desired, even though considerable care might have been expended over the vocal education. And if to this damage to the soft palate must be ascribed a fair share of the defect in the intonation of later years, Brophy's modification in operating is an important and valuable one. For when the halves of the hard palate have been forcibly approximated, the borders of the soft palate hang so close together that their adjustment can generally be effected without tension, so that it is unnecessary to make lateral incisions, or in any other way to interfere with the insertion of the tensor palati or with any other element of the velum. In some cases it may be advisable to steady the adjusted halves, and to relieve them of all tension, by the use of a large suture of silver wire the ends of which are secured by a split shot. This keeps the insertion of the tensor palati temporarily at rest.

Inasmuch as vocalisation is greatly dependent upon the anatomical integrity of the soft palate, and as Brophy's method enables the velum to be repaired with less interference with it than does any other operation with which I am acquainted, it might be advisable somewhat to sacrifice the hard palate to the soft if sacrifice were demanded. And this, Brophy affirms, is not the case. He says, indeed, that the palate with a congenital cleft is too large for the lower jaw to the extent of the width of the cleft, and that the approximation of the superior maxillæ is in itself advantageous.

And just as the approximation of the hinder part of the maxillary processes gives assistance in the closure of the cleft in the soft palate, so does the approximation of their anterior part simplify the subsequent operation on the hare-lip.

In conclusion, I would urge that, serious as is the operation on the palate the infant may be expected to survive it.

I have been surprised at the way in which the infants stand it. Brophy goes as far as to say that "the shock following the operation is not so great if performed within the first month, as it would be later in childhood." Of this I am by no means sure, however.

That, inasmuch as the maxillæ are closely approximated, the halves of the velum can be stitched together without tension and without the need of interfering with the attachment of the muscles of the soft palate.

That, as the approximated halves of the soft palate can be sutured without interference with the muscles of the palate, the prospects of securing a natural voice are greatly increased.

That, as the maxillæ have been brought together in front, the subsequent operation upon the hare-lip is rendered much easier of performance, and a more artistic result is obtainable.

Great Cumberland-place, W.

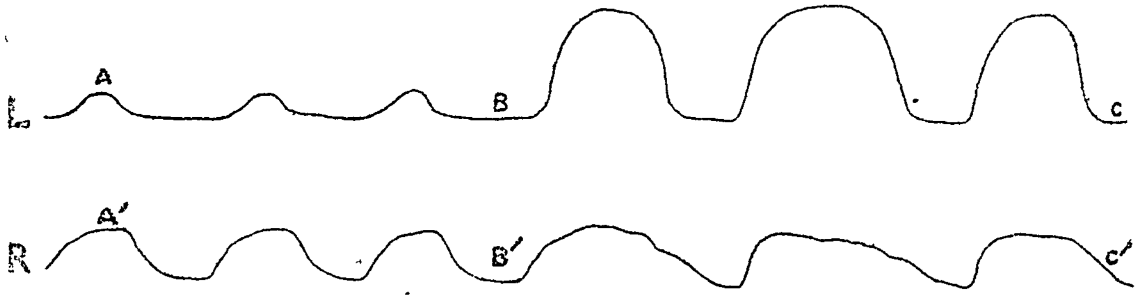
NOTE ON THE RESPIRATORY MOVEMENTS IN HEMIPLEGIA.

BY JUDSON S. BURY, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY; LECTURER ON NEUROLOGY AT THE OWENS COLLEGE, MANCHESTER.

IN THE LANCET of 1895[1] and of 1899[2] Dr. J. Hughlings Jackson pointed out that many cases of hemiplegia gave support to his hypothesis "as to the great differences of the nervous mechanism for the two very different services, organic (respiratory) and animal (voluntary), of the respiratory apparatus." Dr Jackson observed that in some cases of hemiplegia the uppermost part of the costal region of the thoracic cage moves slightly more on the paralysed side of the body in respiration proper (ordinary breathing) and slightly less on that side in voluntary expansion of the cage (deep or forced inspiration). Taking as an illustration a case of left hemiplegia his explanation of these differences in the movements of the thoracic cage is as follows: "The greater amplitude of movement of the left upper cage in respiration proper is, I suggest, owing to destruction of some fibres from the cortex which are for *continuous* inhibition of the left respiratory (medulla) centre; the less amplitude of voluntary expansion of that left upper cage is, I suppose, owing to destruction of some motor fibres from the cortex which, evading the respiratory centre, pass direct to certain left anterior horns and by these act on the intercostal muscles."

Without attempting to discuss how far this explanation is correct I wish to bear witness to the accuracy of the clinical observation which appears to have been somewhat overlooked by subsequent writers. During the last few years I have examined a large number of cases of hemiplegia, both recent and old, and in at least 60 per cent. of them the movement of the upper part of the thoracic cage during ordinary breathing was a little greater on the hemiplegic than on the other side of the body. This difference is indicated in the accompanying tracing which was obtained with the help of my house physician, Dr C. O'Neill, who devoted much time and care to the arrangement of a suitable apparatus. This consists of two air tambours which by means of indiarubber tubes are brought into communication with recording tambours, the levers of which inscribe the movements of the thorax upon a revolving cylinder. Each air tambour is held in position on the chest by a leaden tube which is attached to a firm stand. The tubes being flexible each tambour can be placed evenly on the surface of the chest.

The case from which the tracing was taken was that of a man, aged 50 years, suffering from right hemiplegia of six months' standing. He fell one morning in getting out of bed and it was then found that his right side was paralysed. The attack was not attended by loss of consciousness. On admission to the infirmary last October the hemiplegia was well marked; he was unable to stand and when in bed the movements of the right leg were very feeble. The distribution of the paralysis in the right arm differed from the common type, there being slight power to move the fingers and to flex and to extend the elbow but complete paralysis of all movements at the shoulder joint. The right side of the face was affected and the tongue on protrusion deviated towards the paralysed side. There was no anæsthesia; the speech, which was impaired for a time after the attack, was quite natural. On placing the hands in symmetrical positions on the upper part of the chest, the slight excess of movement on the right side during natural breathing was at once noticed. The movement had more amplitude and it began before and came to an end after that on the left side. When, however, the patient took a deep voluntary breath the excess of movement was on the left side. These variations affected also the lateral movements of the chest, as shown by grasping the lower costal regions. The above observations were confirmed by my clinical clerks and others before they knew anything about the case. It is, indeed, of importance to obtain observations regarding the thoracic movements in any case of hemiplegia from persons who do not know the nature of the patient's ailment and whose judgment, therefore, is an unbiased one.



Respiratory movements in a case of right hemiplegia. R, right side. L, left side. A B and A′ B′, Normal respiration. B C and B′ C′, Forced respiration.

A CASE OF ARTERIAL THROMBOSIS OF GONORRHŒAL ORIGIN.

BY F. CRAVEN MOORE, M.Sc., M.D. VICT.,
M.R.C.P. LOND.,
ASSISTANT TO THE PROFESSOR OF MEDICINE, OWENS COLLEGE, MANCHESTER.

IT has been clearly established by a number of exact observations that an acute gonorrhœal urethritis may be the starting point for a grave septicæmia which may be purely gonococcal or mixed or due to some concomitant organism and that as complications of such systemic infection certain lesions of the vascular system not infrequently obtain. Among these endocarditis and myocarditis are the more usual, thrombo-phlebitis has been noted but is relatively uncommon, whilst arterial thrombosis in such a sequence has, so far as I can ascertain, not hitherto been described, yet that it may occur is apparent from the following example which came under my cognisance whilst pathologist to the Manchester Royal Infirmary.

A man, aged 20 years, was admitted to the Manchester Royal Infirmary, under the care of Mr. W. P. Montgomery, suffering from early dry gangrene of the left leg. He gave the following history. Four days previously to admission he had a slight shiver, became feverish, and in consequence took to bed. After three days he complained of his left leg being cold and painful, especially so in the heel, and also of some pain in the left side of the abdomen. The condition of the leg had come on quite insidiously and became progressively worse. On admission to hospital his general appearance was clearly indicative of some grave general condition: he was pallid, the skin was clammy, and the temperature was 101·5° F. The left leg below the tubercle *of the tibia was cold, waxy, pulseless, and anæsthetic.* The three outer toes showed commencing mummification and the skin over the instep presented a patch of discolouration. The thigh was warm and apparently quite normal. The right leg also presented no obvious circulatory disturbance. The existence of a purulent discharge from the urethra was noted and the meatus was inflamed, but no definite history of gonorrhœal infection could be elicited. That such was the nature of the urethritis, however, was shown by the presence of the gonococcus in large numbers in specimens of the purulent material obtained from the urethra after death. Elsewhere there were no manifestations of other lesions; the heart and the lungs were normal, the spleen was not enlarged, and the urine, containing a trace of albumin and a small amount of purulent débris from the urethra, contained neither blood nor sugar. On the day following admission the general condition of the patient was worse, the evening temperature was 102°, and the left leg now presented considerable discolouration extending up to the knee. It was now noted that pulsation of the left common femoral artery at the pelvic brim could not be felt. On the next day the patient had a cachectic appearance and was sweating profusely. His temperature was 101·6°. Examination of the heart revealed a loud systolic mitral bruit During the evening he complained of his right leg feeling cold and on examination the femoral pulsation was found to be almost impalpable, whilst the limb below the knee was cold, pulseless, and anæsthetic. During the next two days the general condition became markedly worse, ending in coma and death four days after admission to hospital and eight days from the initial rigor. During the whole time blood was never present in the urine.

Necropsy.—Externally the body appeared to be well developed and fairly nourished. The anterior half of the left foot was mummified and the posterior part of the leg as high as one inch above the knee had a livid appearance. On the foot no sharp demarcation was noticeable between the mummified and livid portions nor on the thigh between the latter and the normal skin above. The right foot and leg were dry and livid but there was no indication of mummification. Elsewhere the skin was pale but otherwise normal. From the urethra a small quantity of purulent material was squeezed and removed for examination. With regard to the circulatory system, the pericardium was normal. The heart weighed ten ounces and was normal in form and size; the myocardium was flabby and somewhat friable; of the various cavities, the right auricle and ventricle were somewhat dilated, those of the left side were normal; in none was there any thrombus, old or recent, or any indication of such; the foramen ovale was closed; the valves were quite healthy. [illegible] changes in the myocardium with slight [illegible] were the only morbid changes [illegible] far as the origin of the renal arteries was healthy and free from clot, but below that situation it was completely occluded by firm, reddish grey, adherent thrombus. The upper end of the thrombus was inclined obliquely from the orifice of the left renal artery above down to the wall of the aorta below the orifice of the right renal artery. The left renal artery itself was also occupied by similar but rather softer thrombus extending into its several subdivisions in the hilum. The right renal artery was free from thrombus and appeared to be quite healthy. Below, the thrombus continued in its completely obstructing form into the common iliac arteries and along these into the external and internal iliac arteries on both sides. In the external iliac arteries it extended on the left side into the common femoral artery and on the right side to within half an inch of the pelvic brim. The internal iliac arteries and their secondary branches were similarly occupied by thrombus. The remainder of the arterial system was normal. The veins throughout were free from thrombus or other obvious lesion. With regard to the respiratory system, the lungs were the seat of passive congestion and the postero-inferior parts were somewhat friable; otherwise they were normal, as also were the pleuræ and the air passages. As to the digestive system, beyond fatty degeneration in the liver there were no features of note. The condition of the genito-urinary system was as follows. The right kidney was the seat of well-marked recent passive congestion. The left kidney, in consequence of occlusion of its artery, was almost completely necrosed; it was enlarged, weighed seven and a half ounces, was normal in shape, of a pale yellowish colour, and firm, its capsule being slightly adherent, and on section the whole parenchyma except a small area of cortex at the upper end and the tips of the pyramids presented the appearances of coagulation necrosis. The branches of the left renal artery in the hilum and one or two in the boundary zone were occupied by adherent, soft, red thrombus. The ureters and bladder were normal, the urethra was the seat of a well-marked purulent catarrh specially marked in its posterior part, and in the prostate one or two tiny foci of suppuration were visible on section. The genital glands and ducts were normal.

Microscopical examination.—Sections of various portions of the thrombosed arteries showed similar appearances. The lumen of the vessel was completely occupied by thrombus which in places, especially close to the walls, had a fibrino-cellular structure and in other parts had the appearance of more recent red clot. Of the arterial wall the adventitia and media were apparently normal; the intima, however, had in many plac[illegible] here and there remains of it [illegible] proliferating and degenera[illegible] which could be traced some [illegible] ous. Sections stained with the basic aniline dyes showed the existence of a few scattered diplococci—decolourised by Gram's method—in the peripheral portions of the thrombus. No cultural examination of the blood was undertaken either during life or after death.

The results of the pathological investigation of this remarkable case leave, I think, little doubt as to the causal relation between the gonorrhœal urethritis and the curiously localised arterial thrombosis which was responsible for the gangrene of the extremities. The precise pathogenesis of the thrombosis—a sufficiently striking event in such a situation apart from it [illegible] some consideration. The [illegible] suggested itself at the necro[illegible] deal with embolic obstructi[illegible] the left the more complet[illegible] lodged at the bifurcation of the aorta and that this had induced secondary thrombosis. Further consideration, however, rendered this view barely tenable. In the first place, the thrombus presented no such differentiation as would obtain under these conditions; secondly, its occurrence in the small intrapelvic branches of the internal iliac arteries and its limited extent in the external iliac arteries would be difficult of [illegible] grounds; and lastly, though specially [illegible] embolism elsewhere could be [illegible] ce of an embolus. Such a hypothesis would necessitate an embolus of considerable size and accordingly the possibility of a dislodged cardiac thrombus was inquired into, but neither in the left nor in the right cavities of the heart was there any indication of thrombus formation and whilst the absence of dilatation of the cavities on the left side precluded such a possibility the closed foramen ovale eliminated the slightly dilated cavities of the right side from being its source. It remained then that the thrombosis was a primary process depending on some alteration in the arterial wall and possibly on some [illegible] composition of the blood [illegible] irregular masses of red thrombus in the more central parts—would indicate that one had to do with an acute type of endarteritis with sequential thrombosis. The finding of gonococci in this situation points to that organism as the causal factor in the production of the initial lesion of the arterial wall.

As regards the method of infection two possibilities suggest themselves: (1) infection of small branches, possibly prostatic, of the internal iliac arteries and the development of an ascending gonorrhœal thrombo-arteritis; or (2) infection of the intima of the common iliac arteries by organisms present in the general circulation. The former possibility is difficult of acceptance in that it involves an ascending thrombo-arteritis against the strong blood stream; the second, receiving some measure of credence from the fact that the aortic bifurcation and the commencement of the common iliac arteries are commonly early situations for the appearance of the intimal lesions of atheroma, seems the more probable but leaves the ultimate distribution of the thrombosis somewhat ambiguous. Although no cultural examination of the blood was undertaken the clinical manifestations in themselves afford strong evidence of the existence of a gonorrhœal septicæmia, and of this the thrombosis must be regarded as a local complication.

Manchester.

A NEW SILVER SALT IN THE TREATMENT OF GONORRHŒA.

BY J. S. PURDY, M.B., C.M. ABERD., D.P.H. CANTAB.,
RESIDENT SURGEON TO THE LONDON LOCK HOSPITAL.

DURING the last nine months I have had an opportunity of contrasting the results of different methods, or rather variations in the usual method, of the treatment of gonorrhœa. With each and every treatment I have seen good results. With each and every treatment I have seen cases which showed little improvement. On referring to the records of cases at the Lock Hospital, whilst there has been little or no change in the routine of treatment it is worthy of note that as regards the number and severity of complications there has been a distinct improvement. Of course, in reviewing several thousands of cases one can only speak in generalities. In comparing the effects of different remedies one must remember the different conditions for which they are applied. Thus, a method or remedy which gives excellent results in acute anterior urethritis may be quite useless and even harmful in cases of posterior urethritis. Certainly some cases of the latter condition may occur, not in spite of, but on account of, the treatment in the first phase of the disease. It is to avoid doing a possible harm where there is just a probability of not doing much good that some surgeons prefer not to interfere locally in the treatment of acute anterior urethritis. Others do not go so far as always to taboo local treatment. Preferring to reserve more active local measures until the discharge has been diminished they commence with the administration of balsamics, of which pulvis cubebæ seems to be with them the most popular. It is only when one comes to look at the results in a special hospital with several thousands of cases, that one is struck with the fact that the best results in the aggregate have been obtained by a combination of medicinal and local treatment. I must confess that during the earlier months of my work here I was inclined to ascribe the best results to treatment simply with pulvis cubebæ (two drachms three times a day after food in a tumblerful of water). When in addition the bowels were freely opened with saline laxatives it was not uncommon to have patients reporting that the discharge had ceased in a fortnight. The presence of "floaters" in the urine, however, indicated a continuance of treatment. Though cases remained free from obvious discharge for three weeks the persistence of flocculi in the urine, together with the frequency of relapses, showed that to secure the best results in this condition something more was required than mere medicinal treatment.

On going into the cases of ordinary acute anterior gonorrhœal urethritis treated with resin of copaiba or sandalwood oil, together with injections of sulphate, sulphocarbolate or permanganate of zinc (two grains to the ounce) one found that once the discharge had ceased "floaters" more speedily disappeared from the urine and a permanent cure was more frequently obtained. Certainly relapses were comparatively infrequent as compared with those cases which had received no local treatment. The usual routine was to continue the injections for one week after the cessation of the discharge, gradually reducing the strength by the addition of warm water. Medicinal treatment was continued for at least two weeks after that. As a rule when this was carried out, the restrictions as to total abstinence being rigidly observed, there was no return of the discharge, certainly not of the patient for treatment (so frequent an occurrence when medicine only was given). To effect a cure in six weeks with this treatment is considered an unusually good result.

With regard to the efficiency of the different constituents of injections there is little to choose among those in ordinary use. As many cases of acute anterior gonorrhœal urethritis are now cured within a month by systematic irrigation, for urethral injections to maintain a reputation for efficiency and rapidity it will be necessary to show that similar results can be obtained by this method, which is simpler and can be carried out by the patient himself. It has long been recognised that if in the treatment of gonorrhœa we could introduce into the urethra some solution which would inhibit or even destroy the viability of the gonococcus and at the same time cause no injury to the delicate mucosa we should practically have solved the question as to the most efficient remedy in the local treatment of gonorrhœa. Such an injection, whilst killing the gonococcus *in situ*, must at the same time not aggravate the local inflammatory condition. A suspicion never ought to arise in the event of sequelæ, such as strictures, that the caustic action of the injection may have been a factor in their origin Injections in ordinary use when sufficiently strong to act as antiseptics are also caustics. When not sufficiently strong to be caustic their antiseptic powers are only slight.

If it were possible to test the bactericidal properties of these remedies, as regards the gonococcus, in the laboratory by direct experiment some definite information might be obtained, but as man is the obligatory host for the gonococcus our means of estimating their value is limited to clinical observations of the results of treatment of the disease in man. As antiseptics for destroying, or disinfectants for inhibiting the growth of, other organisms, such as the pyogenic cocci, more easy of cultivation for experiment in the laboratory, it is known that in the strength used for urethral injections the ordinary sulphates have little power. The solution which in former days gave most promise as a urethral antiseptic was silver nitrate, but even in the strength of two grains to the ounce this salt cannot be used with impunity owing to its caustic action. As the gonococcus may be said to have an intracellular habitat and is found in the submucosa it is necessary for the application to penetrate to that layer.

The introduction of salts of silver in organic combination marked a distinct advance in the treatment of gonorrhœa by injections. But even protargol, which contains only 8 per cent. of silver, cannot be used without discomfort and even damage to the mucous membrane in a strength above 2·5 per cent. Of course, one cannot but admit that it is possible to effect the destruction of the gonococcus with a limited amount of damage to the urethra which is reparable. It was soon evident that the limitations of protargol, though not so quickly reached, were in the main those of its predecessors. The synthetical preparation of another proteid salt containing 30 per cent. of silver suggested a more potent bactericide. This salt in a solution of 5 per cent. was said to cause no pain when applied to the conjunctiva. It was shown to possess high germicidal and penetrating properties. Ophthalmic surgeons spoke highly of it in the treatment of gonorrhœal conjunctivitis. On being injected into the urethra it was shown to be non-irritating in strengths of solution much higher than in the case of those salts in ordinary use in the treatment of gonorrhœa. This salt—known as argyrol—is a combination of silver with a proteid extracted from wheat. It is very soluble in water. Unlike inorganic silver salts it neither coagulates albumin nor precipitates chlorides. An extensive trial of this salt in the United States in the treatment of gonorrhœa has established its claim to recognition. It has also found many advocates in Germany. One is sometimes just a little dubious of remedies which have originated in the United States, sometimes unjustly so, as in this instance. There is sometimes, however, just a little suspicion, to say the least, of exaggeration in the way some preparations have had their virtues vaunted and boomed. But when authorities like Chetwood, Keyes, Martin, and Christian join in their testimony as to the good results of treatment with argyrol one must at least grant it a fair trial. Christian[1] of Philadelphia gave an account last year of 49 cases of which a complete record had been kept and the discharge microscopically examined The direct effect upon the amount of the discharge was as follows Prompt cessation in 31 cases, more gradual reduction in 14 cases, and very little in three cases Gonococci disappeared in two days in four cases, in four days in eight cases, in six days in eight cases, in eight days in six cases, in ten days in ten cases, in 14 days in eight cases, and persisted over three weeks in five cases Thus in 4 ompletely disappeared from the With regard to the duration (that nine cases were cured in two weeks 17 cases in three weeks, seven cases in six weeks, and three cases in eight weeks

---

[1] Medical Record, vol. lxii., 1902

Swinburne[2] of New York reported the results of treatment in 350 cases of gonorrhœa in all stages of the disease He sums up his results thus "This drug has decided gonococcidal powers, it has a decided effect in reducing and allaying the inflammation of the disease, it can be used safely in almost any strength and at any stage of the disease I have not seen any unpleasant symptoms due to the use of the drug" (In some cases a solution of 20 per cent argyrol was used)

In June and July of the present year a few cases of gonorrhœa treated at the Lock Hospital with injections of argyrol, combined with the internal administration of resin of *copaiba gave results sufficiently good to suggest* a further trial As a test of efficiency the effects of injections were observed without any medicinal treatment other than some simple saline aperient A case of gonorrhœal *acute anterior urethritis (No 4405 of the out patient* department) treated first on Sept 2nd for a discharge of four days duration with copaiba and injections of zinc sulphate, reported slight improvement at the end of a week *A film showed gonococci in the discharge* on Sept. 9th From that date no medicine was given Injections thrice daily of a 5 per cent solution of argyrol was the sole treatment The urethra having been washed out with warm water, the injection was held in the urethra for five minutes On Sept 16th this patient reported that after using the injection for two days the discharge had ceased Flocculi were however, seen in the urine A film of the deposit, obtained by allowing the urine to stand over night in a tall cylindrical vessel showed gonococci still present On the 30th the patient reported that there had been no return of the discharge even after taking beer No "floaters" were seen in the urine No gonococci were found

Another case in which argyrol was the only treatment was
that of a man, admitted as an in patient and discharge of
five weeks' duration In this case I was ab v that al e bacterio
scopic examinations daily On Oct 2c term commenced
injections of argyrol, 5 per cent, ever l greate ours The
urethra before each injection was washe olescents th a weak
solution of boric acid Two drachms (at all ag solution
were used at each injection and retained clic the t es in the
urethra Next morning after seven injec ood name was no
visible discharge "Floaters were, h suggest present in
the urine and gonococci were found Or ycles 5th the urine
was clear Thus after seven days' trea orge this patient
vork atte has had no
ly con curre twice a day
ited
with Dr charge of 14
days' duration was put on argyrol Afte ree days treat
ment the discharge quite disappeared re fortunately, as
soon as the discharge ceased the patient l d o the hospital and
as to this ca nen
idoors with ar er rol was irrigated
This was a l
rheumatism with a chronic gleety discharg
responded to other treatment for four
admitted on Nov 22nd, his urine was quite normal by the 29th

The last patient *treated in hospital* had a *gonorrhœal* discharge (a third attack) of two months' duration After two days of argyrol injections there was no visible discharge This man's urine however, did not become clear and free from flocculi until *after* 26 days treatment with argyrol com of cubebs and salol

patients worthy of special mention is that of a patient who first came under treatment at the Lock Hospital on August 18th with a gonorrhœal discharge which had lasted "off *and on*" *for* two years This man having contracted the disease in America had been treated at Chicago and also by residence at the hot springs Arkansas He was put on a 10 per cent solution of argyrol on Nov 3rd A fortnight *later he reported* the cessation of the discharge after one week s treatment by injections combined with sandal wood oil Another case was that of an out patient (No 950) who had been treated from August 31st until Oct 21st with *copaiba and* injections of sulphate of zinc 16 days' treatment with argyrol stopped the discharge, of which there has not been a return up to the present date (Dec 7th) In six out of *other ten cases treated with argyrol I have* seen excellent results following an early stoppage of discharge

In five out of seven cases of acute anterior urethritis, where *treatment* was *commenced* early *in first attacks*, a cure was practically assured within a month By a cure I mean that the urine was clear, normal, and free from gonococci and that after discontinuing treatment for six *weeks there was no relapse The cases which gave no* improvement were all cases of chronic gleet in men who had become *habitues* of the hospital and in whom it was tried as a forlorn hope These cases had responded to no previous *treatment and certainly* did *not come under the category of* acute anterior urethritis

It is claimed by our American *confreres* who have published such convincing proof of the efficacy of this salt *in the treatment of gonorrhœa that its superiority over* other silver preparations as a bactericide lies in its high percentage of silver Whether this is capable of explanation by the theory of ionisation is a question for a chemical physicist *In support of the statement that its effect on the mucous membrane* is bland and non *irritating* patients told me that after using argyrol pain on micturition ceased They expressed a preference for this injection when others had been used *previously I have seen no complications during* its use Chordee had not to be treated in any case in which argyrol was used The only objection to the use of this salt which has come under my notice is its cost which certainly prohibits its *extensive use in hospital and dis*pensary practice where the more standard remedies give sufficiently good results at a very small outlay Like other silver preparations it causes stains on linen and underclothing These are *however, easily removed* by a *solution* of iodide of potassium and warm water With regard to rapidity of action and permanency of cure however, I have seen no results from other injections which equal or even approach some *obtained by argyrol It may be of interest* to mention that I have seen this salt used with benefit in a solution of 50 per cent for tertiary syphilitic ulcers and syphilitic lesions of the mucous membrane of the tongue, mouth and *nose*

With regard to posterior urethritis the method of treatment which seems to give most chance of success is one of intravesical irrigation The technique may be that known as Janet s with or without the *modifications of apparatus introduced* by Valentine or Chetwood For those who like myself do not care for complicated apparatus an ordinary douche tin (shaped like an inverted cone) an indiarubber tube five *feet long an ordinary burette clip and a glass* nozzle give very good results That many complications are said to have been caused or aggravated by this treatment is an allegation to which my attention has been often drawn *In the only* case which has so far come under my notice if the epididymitis could honestly have been ascribed to the treatment, it was rather manipulation than the method itself which Certainly one would hesitate to allow the t to experiment on himself with this treatment ho e er I am inclined to think that with care in use and a simplifying of the complicated apparatus, often *advocated* but seldom seen in this country this method is destined gradually to supersede older methods of treatment many of which exc pt in the hands of the most skilled in ur genitary practice only tend to aggravate a condition difficult to treat successfully at any time However good the results from local treatment one must continue medicinal treatment As far as I have been able to judge fr m the results at the London Lock Hospital pulvis cubebæ resin of copaiba, and sandal wood oil all re equally well

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE AFTER-HISTORY OF A CASE OF EXTRA-GENITAL SYPHILIS; CHANCRE AT THE INNER CANTHUS; INTERSTITIAL KERATITIS IN THE PATIENT AND IN ONE OF HER CHILDREN.

By SIMEON SNELL, F.R.C.S. EDIN., L.R.C.P. LOND., M.R.C.S. ENG.,
OPHTHALMIC SURGEON TO THE ROYAL INFIRMARY, AND PROFESSOR OF OPHTHALMOLOGY IN UNIVERSITY COLLEGE, SHEFFIELD.

A YOUNG woman, aged 21 years, came under my notice at the Royal Infirmary, Sheffield, in August, 1882, for a chancre of the inner canthus. Previously she had been a healthy girl. At that time she was a nurse and among the children under her charge was a baby, aged five months, who had had—and, indeed, had at the time of her attendance—a rash on her body, also thrush, a sore nose, and snuffles. The nurse was in the habit of fondling and kissing the child a great deal. The chancre at the inner canthus involved the integument at the commissure and both eyelids and was about the size of a shilling. The gland in front of the ear and the submaxillary glands were indurated. It had begun as a pimple six or seven weeks before she came under observation. On her face was a scanty papular rash; she had sore-throat with slight ulceration of the left tonsil and her hair was falling out. Later she suffered from mucous tubercles on the vulva. (The case was recorded in vol. iii. of the Transactions of the Ophthalmological Society of the United Kingdom.) At the time of inoculation the patient was engaged to be married and it had been intended that the marriage should take place immediately. She was advised to defer it. About ten years later I again saw the patient and found that in consequence of what was said to her the marriage had been postponed, but only for nine months. She had had six children and never until the last time had she gone to full time with them. The first child was born at seven months, the second at eight months, the next three births were also premature, and there was a miscarriage between the fourth and fifth births. The sixth child was healthy until she was about ten months old, when she suffered from convulsions and she had since then been paralysed on the left side. There had been no subsequent pregnancies. The patient herself was well and was by no means as old-looking as many at her age would be. Beyond an attack of rheumatic fever her health had been good. Th healing of the chancre had left some epiphora, but beyc that to the casual observer it had *occasioned but little* alteration. There was no evidence of the husband having suffered at all from syphilis.

The infant who had occasioned the inoculation was brought to me in 1889 in consequence of her suffering from interstitial keratitis. The child had an almost typical appearance of face, with crushed-in nose and Hutchinson's teeth, and she later became afflicted with the deafness met with in cases of inherited specific disease. The history of syphilis in the father (then deceased) was complete and the mother was syphilised before she became pregnant with this child. The father died in 1885 and there were no children subsequently to the one specially mentioned.

Two or three years ago one of the children of the original patient, a boy, aged nine years, came under treatment for interstitial corneitis The condition occurred first in one eye and subsequently the other eye became similarly affected.

At the latter end of March of the present year (1903) the original patient herself came to me with typical interstitial keratitis in the left eye from which she has since recovered. She gave the following history with regard to her children. She had had two miscarriages, seven stillborn children, and four children born alive. There were, as already mentioned, five still-born children before one was born alive. This last, a girl, is now aged 14 years Of the children born alive, one died when eight weeks old, another is paralysed on one side, a third is the one mentioned above as having been under treatment for keratitis, and the fourth is healthy.

The above case is an interesting one for many reasons among which are the following: (1) the situation of the chancre; (2) the characteristic history of the patient's children; (3) the fact that one of the children came under treatment for typical interstitial keratitis; and (4) the circumstance that the patient herself suffered from interstitial keratitis which is only rarely met with in instances of acquired syphilis and which is *additionally* interesting in this case from the complete history that can be recorded and from the late appearance of the keratitis.

Sheffield.

NOTE ON THE SIMULTANEOUS OCCURRENCE OF TWO ACUTELY DEVELOPED CUTANEOUS LESIONS.

BY H. W. SYERS, M A., M.D. CANTAB.

A FEW weeks ago a boy aged nine years was brought to me in the out-patient room of the Great Northern Central Hospital suffering from a rash on the legs of two or three days' standing. He was a well-grown boy and complained of much pain and tenderness over the front of the tibiæ. As I anticipated, the malady proved to be erythema nodosum, and a severe form of the affection, as both shins were practically covered with the lesions. I was then informed that there was yet another rash of a few days' duration situated on the front of the abdomen and extending round the waist. Examination revealed the presence of numerous dark red papules in the locality mentioned, each of about the size of a pin's head. The rash was not present elsewhere. Some slight irritation was complained of, but otherwise this rash has been unattended with symptoms. It was not possible to form an accurate diagnosis as to the nature of the second rash and I contented myself with treating the erythema nodosum.

Three days later I again saw the patient. The erythema was in process of resolution but the spots on the abdomen and around the waist were much more numerous and presented the same characters as before. He came again a week after his first attendance and now the nature of the second rash was perfectly obvious: it was psoriasis. Many of the spots were covered with white scales and not a few had run together into sheets which were not, however, of any great size. At this time the erythema nodosum had prac lly died away but much *pigmentation* was left. The b ever ing through a perfectly typical attack of psori canno urly acute, but the elbows and knees are not mucou h, in any way affected. rse, one this case, as in many others I have seen, struction y of rheumatism even of the typically to the ur hat malady, and the heart was perfectly at the lim d the child ever suffered from chorea. ached, were previous attack either of psoriasis or erythe al prepa n.

In my exp t. of the case is unique. I have never seen the simultan salt ir evelopment of two distinct cutaneous affections suc when those which occurred in this case. A patient may b high ering from cutaneous syphilis and may then contract geons es and the two eruptions may co-exist. In the same onju eczema may be complicated with other maladies, but howe ve never before seen the rashes of psoriasis and o ghe thema nodosum co-existing in the same patient. he t

A CASE OF S ERSISTENT SUPERFICIAL NASAL HYPERÆMI IN A MAN, AGED 21 YEARS, CURED BY REMOVAL OF ADENOIDS.

BY V. H. WYATT WINGRAVE, M.D. DURH., M R.C.S. ENG.,
PHYSICIAN TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

THE patient complained of intense and persistent redness of his nose of two years' duration. The onset was gradual and he could not associate it with any particular cause. He was a teetotaler and a very moderate smoker and he enjoyed excellent health. Nasal respiration was free and nothing abnormal was to be seen by anterior rhinoscopy. The tip, the alæ, and quite two-thirds of the nose were of an intensely vivid red colour, somewhat shiny, but not swollen, tender, or painful. Being subject to indigestion the patient was forbidden tea and was treated with alkaline tonics and saline aperients. After two months' treatment he showed no improvement, but a prominence of the supranasal vein being noticed the nasopharynx was examined by the mirror and finger, revealing a large crop of adenoids. Their removal was soon followed by diminished redness of the nose, the prominent veins disappeared, and in one month the organ became normal in [illegible] that it affords a striking [illegible] between the supranasal vein and adenoids during a period of life in which neither are commonly found and further increases the already long list of troubles due to neglected adenoids. The subject is of further interest with regard to its pathology which admits of several interpretations. First there is the mechanical, in so far that the adenoids themselves directly interfere with venous return, thereby producing the prominent supranasal venous arch in infants, so often the subject of superstitious dread. Further, again, their interference with breathing leads to a general increase of venous pressure which the vessels in question specially show. A second view is that the adenoids are responsible indirectly by causing a reflex inhibition of a local vaso-motor influence. This may be the interpretation in the present instance, while the first view will be more applicable to children.

MEDICAL SOCIETY OF LONDON.

Discussion on Functional Albuminuria.

A MEETING of this society was held on Dec. 14th, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

The PRESIDENT opened a discussion on Functional Albuminuria. He began by pointing out that it did not lie in the power of hospital physicians to do much to settle the question as to the ultimate fate of individuals suffering from intermittent albuminuria but that it was the general practitioner, who had the opportunity of knowing the family and personal history of their patients, to whom they must look for assistance. The late Sir George Johnson and Dr. Clement Dukes were quoted in favour of the view that albuminuria [illegible] term "functional [illegible] greater exception [illegible] scents," as cases [illegible] t all ages and in [illegible] c, the term suggested by Dr. F. W. Pavy, was not a good name to apply to the condition, as it would seem to suggest that the abnormal condition recurred in regular cycles irrespectively of outside conditions. Though Sir George Johnson had previously described the condition the attention of the profession was first focussed on the occurrence of intermittent albuminuria by a paper contributed to the Guy's Hospital Reports in 1878 by the late Dr. Walter Moxon who brought forward a series of 19 cases. Dr. Moxon concluded his paper with the following remarks: "The occurrence of the albuminuria at a period of life when the sexual system is completing its development, and, further, when its aptitudes are not always under normal control, may raise questions of causation of a kind difficult to obtain certain answers to. Starting so near each other and with so much of close relation in their development, and with common rights of way, so to speak, over not always normally governed apparatus, disturbances of the sexual system might be allowed as likely to reflect disturbances on to the urinary system." The condition designated by Dr. Moxon as remittent albuminuria had also been termed orthostatic or postural albuminuria. Its characteristic feature was that albumin was absent on rising in the morning but appeared after breakfast. In the later part of the day it might again be absent. It had been attributed to a want of tone in the vascular system. The effect of meals on albuminuria varied. In some of the so-called cases of functional albuminuria the amount of albumin was usually not influenced by diet, but in other cases the urine lost all trace of albumin under the influence of an exclusive milk diet and again became albuminous after a meal of solid food. On the other hand, there was another class of case in which exercise and even the erect position of the body had more influence than food in the production of albuminuria. Functional albuminuria might occur at any age but it was most frequently met with at the period of adolescence. It was more common in males than in females. It was usually met with in persons who supposed themselves to be in perfect health, but in some cases languor and palpitations were complained of. The presence of the albumin was often detected in systematic examination for life assurance or previously to entry into the services. The need of a careful microscopical examination of the centrifugalised deposit in order to exclude nephritis was insisted on. As regards the causes of albuminuria in the apparently healthy the following were mentioned: an excessively nitrogenous diet (eggs for example), cold bathing, and violent exercise (such as playing football, bicycling, riding, running, or marching). The sexual factor was also considered. The opinion was expressed that chemistry would yet throw more light on the subject of albuminuria and it was thought that one of the by-paths to be investigated was the state of the blood.

Dr. J. ROSE BRADFORD defined functional albuminuria as the occurrence of albuminuria in the apparently healthy. He then discussed as possible causes of the condition latent renal disease of an organic character, the subsidence or onset of renal disease, and accidental albuminuria due to spermatorrhœa or the presence of a discharge such as gleet. It might also be associated with diet, posture, exercise, fatigue, or bathing. Posture was the most important of these. The only clearly established pathological cause of albuminuria was some toxic agent—metallic poisons, ptomaines, and bacterial toxins, substances present in the blood of all animals. But these were obviously absent in most cases of functional albuminuria. Reflex vaso-motor mechanisms of a complex character were called into play when the body assumed the upright position. Posture was probably the main cause of functional albuminuria. Postural variation in the amount of albumin was observed even in organic albuminuria.

Dr SAMUEL WEST concurred with the previous speaker in defining functional albuminuria as albuminuria in the apparently healthy. Albuminuria was never physiological in the sense that it could be shown by the ordinary tests on the urine of any and every one. By delicate tests and repeated examination the percentage of apparently healthy persons affected with albuminuria might reach as high as 40, but in half of these it was nucleo-albumin and in another quarter the trace of albumin was very minute. Thus 10 per cent. were left in which albumin could be found by testing in the ordinary way. The frequency of functional albuminuria varied greatly with age, being fairly high in children, and rising gradually from the age of 25 throughout the rest of life. Among schoolboys and young adults there were two groups—in one the subjects were florid, vigorous, with good or high pulse tension; in the other, pale, flabby, with low pulse tension. These groups probably differed in pathology and prognosis. Of these boys most got well; in some the albumin persisted without other sign of ill-health. In a few signs of renal disease developed. There was no reason in either of these cases to refer the albuminuria to sexual development, still less to masturbation. Statistics proved that functional albuminuria increased the risk to life, especially as age advanced. Throughout life the relation of these cases to granular kidney was important, and thus the association of albuminuria with arterial thickening was very suspicious even in the young. So far as life assurance was concerned the rule was correct—above 40 to reject, between 30 and 40 to increase the premium, between 20 and 30 to make a substantial addition, and to reject all cases with thickened arteries as well as albuminuria. He arrived at the conclusion that functional albuminuria was, strictly speaking, never physiological but always pathological, though not always renal.

Dr. PAVY demurred to the use of the term "physiological," though the term "functional" as applied to albuminuria might be appropriate, just as there might be functional [illegible] disease of the stomach [illegible] disease. He could not [illegible] incipient stage of organ[illegible] cases for upwards of 15 years. Posture was a prominent factor in causation of the condition. Diet did not, in his experience, play an important part; excessive exercise, however, was important as was over brain work. An unstable vascular system was often present and in such cases fully explained the occurrence of functional albuminuria.

Dr. A. E. GARROD recalled the circumstance that Dr. K. A. H. Mörner (Stockholm) had shown that nucleo-albumin, formed by a combination of serum albumin with chondroitin-sulphuric acid was a normal constituent of the urine. Dr. Garrod also referred to oxaluria as a definite cause in his experience of transient albuminuria and even hæmaturia might occur in some of such cases as the result of a surfeit of rhubarb or strawberries. In short, the proteid-retaining mechanism of the kidneys, whatever it was, was a lax one and many of the albumoses easily slipped through. Consequently a very slight departure from normal might easily allow the transudation of serum albumin. The prognosis of functional albuminuria was certainly favourable in a great many cases and Dr. Garrod doubted if it ever developed into granular kidney or other serious organic disease. Nevertheless, local or partial disease of one or other kidney was a possible cause which should be borne in mind.

Mr. H. G ARMSTRONG had studied the condition during 20 years at Wellington College. He would divide functional albuminuria into three varieties: (1) occasional, which was an extremely frequent condition; (2) intermittent, which occurred in from 10 to 15 per cent. of the boys; and (3) permanent, of which kind he could only remember about six cases. Mr. Armstrong did not connect the condition with masturbation. Certain symptoms might be associated with functional albuminuria, and especially fainting; and in his view such cases were often emotional in origin, improvement taking place when the patients were allowed to work and to play games.

CLINICAL SOCIETY OF LONDON.

Congenital Narrowness of the Pyloric Orifice a Cause of Chronic Gastric Disease in the Adult; Seven Cases Successfully Treated by Operation.—Gastro-enterostomy for Simple Ulcer of the Stomach and Duodenum.

A MEETING of this society was held on Dec. 11th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Mr. A. ERNEST MAYLARD (Glasgow) read a paper on Congenital Narrowness of the Pyloric Orifice a Cause of Chronic Gastric Disease in the Adult, illustrated by seven cases successfully treated by operation. In operating upon several cases of chronic gastric disease; a very typical form of narrowing of the pyloric orifice had been observed. While there was nothing externally to be noted, on internal examination a uniform sharp, ring-like constriction of the pylorus was found to exist. In some cases the ring was too narrow to admit the insertion of the apex of the finger. The construction put upon this condition was that it resulted from an over-development of the pyloric valve, which normally gave an orifice of from 12 to 15 millimetres in diameter. By excessive reduplication of the mucous membrane the valve might measure from two to ten millimetres. The condition was not one to be confounded with the more generally known congenital stenosis of infancy, where there was always hypertrophy in addition to the constriction. The patients were usually young adults who had suffered for years from gradually increasing gastric symptoms, quite indefinite at the onset but becoming more distinct later, and sometimes definitely suggesting pyloric obstruction. Dieting and medicinal treatment usually produced marked improvement but a return to the usual mode of living caused a recrudescence of all the symptoms. Gastric dilatation was sometimes present and was usually found to depend upon any temporary deviation from, or indiscretion in, the needful careful attention to diet. The history of seven cases was given. The patients were of the female sex, the ages being 20, 21, 27, 27, 27, 31, and 46 years. In all the symptoms had commenced insidiously and were at first of a simple dyspeptic character but afterwards showed more marked gastric disturbances. In five out of the seven cases the patients were in good social position and in two they were members of very healthy families. All were under the normal standard in stature and build but presented otherwise no defective physical or constitutional features except such as were dependent upon the gastric condition. In two the symptoms had existed as long as could be remembered. In all treatment had been tried by several medical men by various measures, usually with temporary improvement, but never with any permanently good result. Operation had been undertaken in all cases with the object of giving the stomach physiological rest, the chronicity of the complaint and its intractableness to all conservative treatment being considered a sufficient reason for operation. Posterior gastro-jejunostomy had been carried out in all. Improvement took place almost at once in some instances but not till a few months afterwards in others. Four out of the seven patients were at the end of a year's time practically cured of a condition that had existed for years. Two were still improving and one only recently operated upon was rapidly progressing favourably. In conclusion, Mr. Maylard said that he thought the condition of congenital narrowness of the pyloric orifice a by no means uncommon one. In its comparatively slighter forms it possibly accounted for many cases of gastric irritability in middle age or young adult life, and should always be considered as a not unlikely cause in young adults in whom no other explanation could be given for the chronicity and intractableness of the dyspeptic symptoms. The symptoms were always temporarily relieved by dieting. Of the three operations which might be practised for its relief—pyloroplasty, pylorodiosis, and gastro-jejunostomy—the last was considered the best. It had been employed in all the cases narrated and when executed with due regard to the normal anatomical relation of the stomach to the first part of the jejunum and the proper function of these viscera it gave the best possible results.

Mr. B. G. A. MOYNIHAN (Leeds) read a paper on 100 Cases of Gastro enterostomy for Simple Ulcer of the Stomach or Duodenum. The patients had been operated upon up to Oct. 1st, 1903. Two cases among them had been fatal. 85 patients were operated upon for chronic ulcer with intractable dyspepsia or dilated stomach with one death. 15 patients were operated upon for profuse and recurring hæmorrhage with one death. There were 56 females and 44 males. The youngest patient, a female, was aged 17 years; the two oldest, a male and a female, were each 62 years. The average age was 35 years. In ten cases the induration around a chronic ulcer was so marked that the presence of a "tumour" was recorded. In 58 cases the presence of a single ulcer or of the scar of a single ulcer was noted. In seven the ulcers were described as being multiple. Duodenal ulcer was found alone in nine cases, duodenal ulcer with one or more gastric ulcers being present in 13 cases. Hæmorrhage was the immediate and determining cause of operation in 15 cases. In all of these there had been symptoms of stomach troubles for a shorter or longer time before the onset of the bleeding. Several of these patients were in a desperate condition. In all these patients gastro enterostomy alone without the excision of the ulcer was performed; in not one of them was there any trace of renewed bleeding after the operation. Gastric tetany was observed in greater or less severity in five cases. In three it was slight and affected only the hands and forearms and the calf muscles. In two the patients experienced the utmost agony. The importance of oral and gastric antisepsis was emphasised. In 92 of the cases the result of the operation had been from the first as satisfactory as could be wished. Appetite had soon returned and food has been taken in any quantity with relish. All these patients had gained in weight, the gain varying in amount from seven pounds to four and a half stones. In the remaining six cases the after-history had not been so good. In every one of these hyperchlorhydria was pronounced before the operation and had proved a source of pain and inconvenience afterwards. Of the six patients three had improved greatly under medical treatment continued for from three to five months and were now quite well, one was almost well, and two were still under treatment. The last three had all been operated upon within the past eight months.—Dr. H. BATTY SHAW asked whether Mr. Moynihan had known a peptic ulcer to form after the operation of gastro-enterostomy. An American author had shown that it might occur experimentally in dogs.—Mr. J. H. MORGAN remarked on the fact that both these valuable papers came from surgeons practising in the north of Great Britain. Was there anything in the diet to account for this? Mr. Moynihan's result of a 2 per cent. mortality was most satisfactory.—Mr. A. E. J. BARKER had always regarded gastro-enterostomy as by far the best operation for gastric ulcer and the results now laid before the society fully confirmed this view. As to the cases of pyloric stricture brought forward by Mr. Maylard, the congenital origin of these must remain an open question. Dr. *Norman Moore* had brought the matter before that society, but the congenital origin of such cases was always a little doubtful. Pyloritis and peripyloritis might cause pyloric constrictions, just as gleet might be followed by urethral spasm and hypertrophy. He considered that suturing was a better method than the employment of mechanical appliances.—Mr. ERNST MICHELS asked Mr. Moynihan what percentage of cases of gastric ulcer were operated on out of the total *number seen.*—Mr. C. R. KEYSER asked whether the inferior method might not be regarded as better than superior gastro-enterostomy and advocated the employment of a single layer of sutures.—Mr. LEONARD A. BIDWELL, referring to the cases of pyloric stenosis, said that his experience led him to believe that Mr. Maylard's cases were due to repeated spasm of the pylorus of possi [illegible] near to him any e [illegible] As regards Mr. M [illegible] subsequent history and what proportion of them had relapsed.—Dr. H. A. CALEY asked Mr. Moynihan what proportion of his cases had been treated by rectal feeding, diet, and other medicinal measures before operation was resorted to.—*Dr. EDMUND CAUTLEY did not think* in regard to Mr. Maylard's cases that the narrowness of the pylorus could be definitely stated to be congenital or sufficient to cause the *condition of the stomach found. Had there been any* stricture he would have expected that there would have been definite hypertrophy of the muscular walls of the stomach adjacent to the *pylorus. He* asked what Mr. Maylard thought was the natural size of the pylorus and suggested that it varied considerably in different individuals. Possibly the symptoms and the dilatation of the stomach were dependent on *gastric conditions arising from* unsuitable food or alcohol. In regard to Mr. Moynihan's cases it seemed remarkable that such a large proportion should need operation.—Dr. J. W. RUSSELL (Birmingham) referred to 86 cases of gastric ulcer attended with hæmatemesis He had traced the after-history of about half of these. Of those so traced about 45 per cent. had suffered no relapse and had remained well, *10 per cent. were subject to periodic* relapses, and about 45 per cent. were in a miserable condition with persistent vomiting. These last would be suitable for operation.—Mr. A. PEARCE GOULD congratulated Mr. Moynihan on his success but asked if gastric ulcer did not *relapse after operation*, narrating *one case in* which the results of operation had been disappointing. Mr. MAYLARD, in reply, said that his chief reason for considering that his cases were of congenital origin was the extreme regularity of the feeling of the pyloric opening and the fact that thickening was absent. He thought people in good social position were less likely to give way to excesses in unsuitable diet. It was not possible to obtain a trustworthy gauge of the size of the pyloric aperture post *mortem.—Mr. MOYNIHAN, in reply, stated that he thought* there was hardly anything worse than the bad tea and bread consumed by many northerners. The proportion of cases operated upon to those seen by him had been about 25 per cent. As far as he could judge, the surgeon saw the cases somewhat earlier in the north than in London. That much suffering might be avoided by timely operation he was convinced.

EPIDEMIOLOGICAL SOCIETY.

Sleeping Sickness.

A MEETING of this society was held on Dec. 11th, Dr. B. A. *WHITELEGGE, the President, being in the chair.*

After the transaction of formal business Dr. LOUIS W. SAMBON, lecturer at the London School of Tropical Medicine, read a paper on Sleeping Sickness. *He began* by referring to the recent spread of the disease in Africa and specially its extension to the Victoria Nyanza and its islands. He then gave an account of the history of the study of the disease, *from the first* researches of Winterbottom made exactly 100 years ago to those of Castellani, Bruce, Brumpt, and Manson. As a sequel to the reference made to Castellani's discovery of a trypanosome in sleeping sickness, Dr. Sambon proceeded to give a history of the gradual acquaintance of observers with the genus trypanosoma, mentioning the trypanosomas of surra, nagana, mal de caderos, dourine, and the African gall sickness. He then mentioned the discovery of a trypanosome in man by Nepveu, Ford, and Dutton. He said that as soon as Castellani discovered a trypanosome *in sleeping sickness the idea of a fly* as the carrier of the infection came very naturally to all those who had any knowledge of trypanosoma disease. The first to publish any definite opinion on the matter, not merely as a hypothesis, but as the outcome of the *concurrence of* well-established *facts*, were Brumpt and himself. It would be idle to discuss priority in the matter. *He expressed his views* in an article on sleeping sickness which was *published in the Journal of Tropical Medicine* on July 1st, 1903 Brumpt's observations were published on July 2nd. However, the idea had come to both simultaneously and independently the day they learnt that a *trypanosoma* had been discovered in cases of sleeping sickness. Brumpt spoke of glossina morsitans. He (Dr. Sambon) specified a West African species, and more especially glossina palpalis; but he attached no great importance to this because he had books and specimens at hand, while Brumpt was in the wilds of the Congo. Besides various species of the germs, glossina might be capable of transmitting sleeping sickness just as various species of anopheles were able to disseminate sub-tertian fever. Their respective communications did not merely suggest a glossina as the carrier of sleeping sickness because a trypanosoma had been discovered in the disease, and because nagana was *known to be disseminated by glossina, but they were* chiefly intended to support Castellani's discovery by a number of facts derived from the study of the distribution and *life-history of tsetse flies on one side* and the distribution and epidemiology of sleeping sickness on the other. At first Castellani's discovery met with little favour in this country. At the last meeting of *the British Medical Association at Swansea he was the only* one to uphold a causal relationship between Castellani's trypanosome and sleeping sickness. His opinion was based on the analogy between the course, symptoms and anatomical features of sleeping sickness and of the various trypanosoma diseases of cattle generally considered and, more specially, on the striking connexion which existed between the peculiar *distribution of sleeping sickness* and that of tsetse flies. Dr. Sambon stated quite clearly that he could see no morphological distinction between Castellani's trypanosome and trypanosoma Gambiense. He pointed out that the so-called posterior extremity of the trypanosome was in reality *its anterior extremity* and that view had been endorsed by Professor Blumhard, Dr. Geart, and others. He expressed the *opinion that the glossina did not merely carry* the trypanosomes as suggested by Colonel Bruce, but played the part of an alternative host. Considering the very remarkable mode of development which obtained in tsetse flies he further suggested as a working hypothesis that nagana and sleeping sickness might be transmitted not directly by the fly that sucks the blood of *infected animals*, but by its progeny as was known to be the case in the transmission of red-water *fever by rhipicephalus* annulatus and in the transmission of the malignant jaundice of dogs by hæmaphysalis leachi. After minutely discussing the two reports on sleeping sickness by Colonel Bruce and Dr. Nabarro, Dr. Sambon criticised the former's experiments with regard to the transmission of this disease by tsetse flies. Other experiments were made to determine whether the Uganda tsetse fly (glossina palpalis) did carry sleeping sickness. Five monkeys were submitted to the bites of tsetse flies. The flies were previously fed on cases of sleeping sickness and then on *the monkeys eight, 24, and 48* hours after. Hundreds of flies were used in each experiment and after a period of about two months trypanosomes were *found in the blood of the animals experimented upon.* A second set of experiments with flies was then carried out to ascertain whether tsetse flies freshly caught in the vicinity of Entebbe did carry the trypanosomes of sleeping sickness. *Three monkeys were submitted to the bite of* large numbers of flies caught in the vicinity of the hut-tax labourers' camp in Entebbe. All these monkeys showed trypanosomes in their blood after a period averaging between a fortnight and a month. The experiments made by the commissioners with tsetse flies collected at Entebbe and fed on susceptible monkeys after *being fed on cases of sleeping* sickness had been almost unanimously accepted as proving that the trypanosomes of sleeping sickness were transmitted *from the sick to the healthy* by the glossina palpalis and that the fly carried the parasites much in the same way as the vaccinating needle carried the infection of vaccinia from child to child. He did not doubt in the least that the glossina palpalis was a carrier of sleeping sickness; indeed, he had been the first to suggest it. But to his mind the experiments made by Colonel Bruce and his colleagues did not prove the point. In the first place he (Dr. Sambon) did not consider it proved that the fly carried the infection by mere transference. The experiments made by Colonel Bruce with glossina pallidipes and nagana, those made by Rogers with various tabanidæ and surra, and those made by Theiler with hippoboscidæ and gall-sickness only proved that a fly disturbed while sucking the blood of a trypanosoma-infected animal might convey the disease to a healthy animal by means of its blood-soiled proboscis, just as malaria might be conveyed by a needle soiled with infected blood. But this mode of transmission did not seem to be the usual one. It did not explain why nagana was carried exclusively by a glossina and not by the many other blood-sucking animals which attacked horses and cattle outside the fly-belts. It did not explain why sleeping sickness was likewise confined to the tsetse zone and not communicated by the blood-sucking insects and acaridæ which swarmed in the huts of the natives. But there were many other objections against the commissioners' experiments at Entebbe. Those gentlemen did not rear their flies in the laboratory, they collected them at random, and they knew for certain that these flies were already infected because in the second set of experiments they also infected the monkeys they were made to bite soon after being caught and without being previously fed on cases of sleeping sickness. That the trypanosomes which they conveyed were those of sleeping sickness was not in any way proved; on the contrary, the commissioners informed them that they had examined some oxen at Entebbe and found in the blood of those animals a trypanosome which was neither trypanosoma Brucei nor trypanosoma Gambiense. And who could say how many other species of trypanosomes were to be found in the blood of the mammals, birds, batrachians, and fish of Uganda. A very striking fact was that whilst the monkeys bitten by the flies not fed on cases of sleeping sickness contracted the infection within two or three weeks, those bitten by flies fed previously on cases of sleeping sickness did not contract it until after about eight weeks. That proved that the flies did not get the parasite from the blood of the sleeping sickness patients who, as a rule, had hardly any in their peripheral circulation, but that on biting those patients they emptied themselves of some of the parasites they were carrying. Those experiments would have to be repeated in a thoroughly scientific way. Meanwhile he believed that the bond of association between Castellani's trypanosome and glossina palpalis was a far more intimate one. Lastly, Dr. Sambon referred to Sir Patrick's Manson's case of trypanosoma fever in a white woman. That case terminated with the characteristic symptoms of sleeping sickness, thus proving that trypanosoma fever was only an early stage of sleeping sickness and that a trypanosome was the cause of that deadly African scourge.

Sir PATRICK MANSON, having been asked by the President to open a discussion on the paper, said that he felt rather oppressed with a sense of responsibility in doing so. He could not but feel that the discussion was one of very great importance not only to Africa, where really it was a subject of primary importance, but to pathology in general, for the entrance of that protozoon into the field of pathology promised to give new light in places where darkness formerly obtained, and one must be extremely careful in expressing any view upon a subject just as it began to break upon the medical mind. He was especially pleased with the last part of Dr. Sambon's paper—that in which he expressed the hope that questions of priority would not occupy the meeting. They were always thorny subjects and they led to a good deal of bad feeling and so far as his experience extended never to any general profit. Sometimes on a Sunday he had an opportunity of contemplating the manners and customs of the fowl community, and his observations were generally taken between the morning meal and the afternoon meal when the fowls had picked up the last grain of maize and apparently had no chance of getting more food. But even in the community of fowls of that description some enterprising animal would wander from its fellows and by dint of perseverance would sometimes pick up a lob worm in some corner of its habitation. Almost before one had observed the fact that this fowl had made the discovery one also observed that this fortunate fowl was beset by numerous other fowls who rushed to share the profit. As a result the first fowl was very quickly deprived of its morsel and the second fowl succeeded in taking a little bit, and the third, and the fourth, and the fifth, until after a time it was found that the discovery had become the general property of the community with the result that the owner of the fowls, in the long run, benefited by getting a more wholesome and nutritious egg in the morning. He believed that that was a fair simile as to what happened in the field of discovery. One man got hold of a lob-worm and a hundred men could extract part of the *éclat* perhaps, but in the end the whole world benefited by the discovery. He had learnt a lesson in studying the cause of sleeping sickness. Dr. Sambon had told them already that a good many years ago he (Sir Patrick Manson) had found a peculiar parasite in cases of that disease. In a case that Sir Stephen Mackenzie gave him a chance of examining he found a new species of filaria in the blood. He was very much interested in the subject and he found a new parasite, a parasite which differed from the one that was suspected at the time to be the cause of the disease. Further, he was inclined to jump to the conclusion that the new parasite and the disease had an essential relation to each other. The conclusion seemed natural. As soon as he had made the observation he bethought himself how he should pursue the subject and he sent to Africa for specimens of blood from the natives. He sent 10,000 slides to Africa and got about 300 back. In those 300 a good many specimens came from cases of sleeping sickness and in every case of sleeping sickness he found the filaria perstans. By and by Dr. H. Grattan Guinness brought two cases of sleeping sickness to England for the purpose of studying them and put them at his disposal, and he was very much gratified to find in the blood of those cases also the filaria perstans. With evidence of that sort at his disposal he thought it would be beyond the power of resistance of most human natures to say that filaria perstans was not the cause of sleeping sickness. Thank heaven, he resisted the temptation and said that the filaria perstans was very likely to be the cause. However, after pursuing the subject further, he learnt that the same parasite was found in British Guiana and he was somewhat disappointed, because at that time they had no knowledge of sleeping sickness having visited British Guiana. He wrote to a friend there and asked him if he knew of a case resembling it in British Guiana. Writing back his friend said that a native patient had been brought to him suffering from somnolence from which he had great difficulty in waking him. That seemed to encourage the idea that possibly sleeping sickness might exist there and its existence there would further endorse the possibility that the filaria perstans was the cause of the disease. By and by Dr. G. C. Low and Dr. A. Castellani went out to Uganda from the Royal Society to test the connexion of the filaria perstans with sleeping sickness. Their first reports were distinctly in favour of regarding that parasite as the cause of the disease. In one district they found something like 95 per cent.—he did not know the exact figures—of the natives suffering from sleeping sickness due to filaria perstans infection. Subsequently on extending their observations they made the disconcerting discovery that in another district where sleeping sickness was extensive the filaria perstans was scarcely ever found, thus destroying at one stroke the hypothesis on which he had ventured to think he might derive a little credit. Now he was very glad to disallow any connexion between the filaria perstans and sleeping sickness. But as regarded the connexion of the trypanosoma Gambiense with sleeping sickness he thought they should still bear in mind his experience in connexion with the filaria perstans. His belief was that sleeping sickness was caused by the trypanosoma Gambiense, but he could not say that it had been proved. His belief at one time was that sleeping sickness was caused by the filaria perstans but he could not say then that it had been proved. He still thought there was room for further proof on the subject of the distinct and definite connexion between the trypanosoma Gambiense and sleeping sickness. He believed that that parasite was the cause of the disease but he did not know for certain. A case to which Dr. Sambon referred of a man who died from sleeping sickness was another reason for their belief in the relationship of that parasite to, and its being the cause of, the disease. But even that was not sufficient for the scientific mind. They could understand that coincidence even in that case might have something to do with the matter. When Dr. Castellani's and Colonel D. Bruce's discoveries were first made public he was extremely sceptical as to the origin and relationship of the two parasites. For this reason: Colonel Bruce distinctly stated that 28 per cent. of the general population of Uganda, apparently healthy people, had got the trypanosoma Gambiense in their blood. Now sleeping sickness was a disease which certainly predisposed the human body to many kinds of parasitic invasion. In consequence of the paralysing effects of the disease and the indifference of the patient to what went on outside him the carriers of parasites (such as flies, fleas, bugs, and the like) might bite him in that condition with impunity. They could understand that a patient affected with the indifference and languor so characteristic of sleeping sickness would be extremely prone to be bitten in that condition and therefore he was just the person who would exhibit the parasite in his blood. In the same way he was specially subject to invasion for the same cause by the filaria perstans. At the same time that evidence was not what would be regarded as satisfying in science. But when that poor lady in whom Dr. C. W. Daniels had found a good many months ago a trypanosoma Gambiense long before she had exhibited the symptom of languor characteristic of sleeping sickness—a parasite which was evidently the initial cause of her disease when on the Congo—when that lady developed it he thought they had much more definite proof than anything supplied from Uganda or elsewhere. There was no opportunity of her being bitten—nor was there any opportunity for subsequent infection following the primary infection—by the animal, whatever it might be, that introduced the poison. Therefore that case, he thought, was one of great importance. It was not complete proof that that parasite was the cause of the disease. Until they had obtained a pure culture of the trypanosoma from her blood the subject was still one on which they should keep an open mind as to the cause of the disease. In his opinion the strong probability was that that parasite was the cause of the disease but he could not say that the point was essentially and conclusively demonstrated as yet. He hoped that the cultivation experiments made lately by two American scientists in the growth of trypanosoma Gambiense in pure culture and also by Colonel Bruce would be confined to the decision of the question. Until the thing was positively decided one way or another he thought that one incurred a certain amount of responsibility and danger in advising anything in the way of extensive public measures with a view of counteracting the influence of the trypanosoma Gambiense in connexion with sleeping sickness. One would be advising extensive public measures on what might be only speculation and that was somewhat dangerous ground for men to go upon who were responsible for conducting public affairs. Therefore he would urge those interested in that question in connexion with parasitic disease to undertake cultivation experiments and then if they found that the pure culture of the trypanosoma Gambiense injected into monkeys or—if anyone was sufficiently self-sacrificing—into the human being in his own person, if they found that that pure culture produced the symptoms of sleeping sickness, then he would say that the thing was practically proved and he would be content. He would like to point out one or two other things in that connexion which were noteworthy. Colonel Bruce had distinctly proved —and his experiments had been repeated in Paris and elsewhere—that certain species of monkeys were susceptible to trypanosoma infection. That being so, was there any proof that the monkeys of Uganda had got sleeping sickness? He did not think that the experiments by Colonel Bruce of injecting the blood and the cerebro-spinal fluid of patients infected with sleeping sickness into monkeys and subsequently injecting blood from a man with trypanosoma fever, but without sleeping sickness, into the blood of monkeys,—he did not think that those experiments were conclusive at all as to the connexion of the trypanosoma with sleeping sickness. Supposing they assumed that sleeping sickness was an independent disease, depending upon a specific germ, then if they injected two specific germs into a monkey they might induce two diseases, say, trypanosoma fever and sleeping sickness. Or supposing they had a patient suffering from plague and at the same time from relapsing fever, and they took a little of his blood in a hypodermic syringe and injected it into another man's veins and it produced two diseases, plague and relapsing fever, and they found the bacillus pestis and the bacillus spirillum, it would not necessarily follow that the one bacillus was the cause of relapsing fever and the [illegible] experiment as [illegible] trypanosoma [illegible] from those w[illegible] there were [illegible] any epidemic of the disease amongst those animals. He would make one more remark. Dr. Sambon had observed that there was a correspondence between the area in which polyadenitis of the negro was noticed and the sleeping sickness area. He did not know whether Dr. Sambon had seen Dr. C. Christy's report, but Dr. Christy asserted that a large area of country in which the natives were extensively affected with polyadenitis was absolutely free from sleeping sickness. In his mind evidently polyadenitis was not associated with the disease.

Professor E. RAY LANKESTER said he would venture, as one who took a great interest in the subject from a natural history point of view, to make a very few remarks. His own interest in the matter began with the study years ago of the trypanosoma which occurred in the blood of the frog and he believed he was the first to state that and to write about it. He doubted whether it really was right—although he saw that a competent naturalist took the opposite view—to call these parasites in mammalian blood trypanosomas. Might he say that he listened with great pleasure to Sir Patrick Manson's statement which seemed to him to be an extremely interesting account of his views on the subject under discussion and to show a really scientific attitude of mind. Sir Patrick Manson entertained strong presumptive opinions with regard to the filaria perstans but did not commit himself about it. He thought also that Sir Patrick Manson's attitude in regard to the trypanosoma Gambiense was absolutely correct and sound, that was to say, there was strong evidence in favour of the trypanosoma being the cause of sleeping sickness but the question was not what he could call proved. The possibility of another parasite being present in the blood had to be borne in mind. They were getting to know such extraordinarily minute and varied parasites in the blood of the mammalia in tropical countries that they had to be very careful as to the conclusions that they might form. He would further say that he thought it was not desirable to discuss questions of priority by the present occasion. He thought that Dr. Sambon should correct a statement in his paper by a reference to the reports by the commission of the Royal Society in which he would find that Dr. Castellani did not examine those patients, 70 per cent. of whom had the trypanosoma in their blood, until Colonel Bruce arrived. It was Colonel Bruce who initiated the investigation, he having observed the trypanosoma in five cases scattered over some four months—between November and February. But that was a matter which really was not of much interest for the Epidemiological Society. Another point had struck him. Dr. Sambon seemed inclined to claim a kind of priority in suggesting that the glossina palpalis was the carrier of the trypanosoma. Of course, it occurred to many. There was nothing in it. The real interest in the matter was Colonel Bruce finding the glossina palpalis which was not previously known. It was not known that the glossina palpalis really occurred on the shores of Lake Victoria Nyanza but he searched for and found it. [illegible] that a change went on in the interior of the [illegible] which everybody who had [illegible] course entertain. It was no use making a claim to priority in a suggestion of that kind. The suggestion was one which, in his opinion, was not worthy of being regarded as a matter of priority. He had no doubt that a great deal more would be done in the study of that particular trypanosoma in connexion with sleeping sickness and in other ways. They must not be impatient. He thought that a very extraordinary rapidity had been shown in the acquirement of knowledge about the relation of that trypanosoma to sleeping sickness when they remembered that it was only in the beginning of last March that these 28 out of 30 patients, or 70 per cent., were found to have it in their cerebro-spinal fluid and not much time had been lost in the investigation since then and it was still in progress.

Dr. M. E. BRUMPT (Paris), who spoke in French, said: The discovery of Castellani was for myself as well as for Sambon the point of departure of my hypothesis as regards the rôle played by the tsetse fly. Professor Manson doubted on absolutely scientific grounds whether the trypanosoma was the cause of sleeping sickness and whether also it was not that another germ was injected at the same time as that of the trypanosoma. I believe, however, that I am able to say after my researches in Africa and those which I have carried out in Paris in collaboration with Dr. Wurtz that there is an absolute coincidence between the appearance of the trypanosoma and the symptoms of sleeping sickness.

The discussion was adjourned to Jan. 15th, 1904.

EDINBURGH OBSTETRICAL SOCIETY.

Fœtal Thyroid Hypertrophy.—Thyroid Extract in Puerperal Eclampsia.

A MEETING of this society was held on Dec. 9th, Dr. N. T. BREWIS, the President, being in the chair.

Dr. W. E. FOTHERGILL (Manchester) read a paper on Hypertrophy of the Fœtal Thyroid with Maternal Eclampsia. He regarded these two conditions as independent of one another. The eclampsia had been treated with thyroid extract. The case was also one of the five recorded instances of hypertrophy of the thyroid gland in the child following the administration of chlorate of potassium to the mother during pregnancy. The patient was 37 years of age and of gouty Derbyshire ancestry. She was married at 27 years of age, went abroad, and had been under many medical men for dysmenorrhœa. She had two early abortions and a third pregnancy ended at the fourth month in May, 1899. She again became pregnant till November, 1901, but it ended in an incomplete abortion for which she was curetted. Her fifth pregnancy began in April, 1902, while she was wearing a pessary, but this was removed and one or two small sponges were inserted into the vagina during the day if necessary; these afforded her great relief if pain and discomfort were present. As Dr. Fothergill thought it probable that the repeated abortions were due to placental thrombosis he prescribed ten grains of chlorate of potassium and ten minims of tinctura ferri perchloridi with glycerine and quassia thrice daily. This was begun immediately pregnancy was recognised and was continued throughout the gestation, which was undisturbed. The urine was examined several times and was found to be quite normal on Dec. 3rd. It should be noted that the patient's thyroid gland appeared to enlarge to about the usual extent during this pregnancy. On Dec. 7th there was slight swelling of the hands and feet and on the 16th the urine contained 0·2 per cent. of albumin. Five grains of thyroid were given twice daily and she was put on vegetarian diet. On the 25th she had eaten goose and plum pudding and felt ill afterwards, suffering from headache and vomiting On the 29th she passed no urine and that evening two eclamptic seizures occurred. Half a grain of morphia was given hypodermically and hot-water bottles were applied followed by profuse perspiration. Next day she was drowsy and restless and vision was impaired; no urine had been passed, so water was injected into the rectum, calomel was given, and nine five grain thyroid tabloids were administered during the next 24 hours. On the 31st the condition remained unchanged; rectal lavage was repeated and seven thyroid tabloids were given. Urine was passed that evening. On Jan. 1st labour began in the afternoon and at 9 P.M. the head was in the vulva. A little chloroform was given, the tough perineum was incised on either side, and forceps were used to deliver the head. A small female child was easily born; she cried freely immediately and some venous distension in the neck at once became visible. The child was found to have a large solid tumour representing the whole of the thyroid gland and this was covered by an enormously dilated venous plexus. The head and neck became more and more intensely congested and it became clear that the circulation as demanded by the pulmonary respiration could not be established. The child lived only for about one hour after birth. For 24 hours after labour there was complete anuria, but one and three-quarter pints were passed late on the evening of Jan 2nd. Thyroid substance was given to the extent of 30 grains. Next day the urine passed amounted to five pints. Another 15 grains of thyroid were given and its administration was stopped. The pulse-rate was 150. Next day, the 4th, five pints of urine were passed and the pulse fell to 110. After this her condition gradually became normal. At the necropsy on the child an almost angiomatous mass of vessels was found in front of the thyroid. The thymus was normal. The thyroid, completely freed of all other structures, weighed 25·8 grammes; its lobes were equally enlarged and the isthmus was nearly equal in size to one of the lobes. The lobes embraced the trachea, larynx, and œsophagus. Microscopic sections showed uniform structure of a glandular nature. The enlargement was due to overgrowth of all the tissue elements, especially the glandular. The average weight of the thyroid in an infant was from one to two grammes; this one was 25·8 grammes. This case seemed to show benefit from the thyroid treatment of albuminuria of pregnancy; if Dr. Fothergill had given more at first she might not have had eclampsia. He intended to give it a further trial. This case also illustrated the non-interference treatment of the gestation in eclampsia; he believed that labour should not be artificially induced in the presence of convulsions or coma; if labour began before or during the attack it should be conducted with care and patience but without unnecessary delay. Dr. Fothergill then quoted references bearing on the subject from the works and practice of Dr. J. W. Ballantyne, Sir J. Y. Simpson, Professor A R. Simpson, Dr. Angus Macdonald of Edinburgh, and Dr. J. T. Hewetson of Birmingham. Five cases in all had occurred where there was no congenital tendency and where the mother was taking chlorate of potassium. Many mothers took this drug without the child having goitre, but one should try to find out the reason why in certain cases the administration of chlorate of potassium should be associated with the thyroid enlargement in the infant. Experience showed that the administration of this drug in cases of habitual abortion was frequently followed by a full-time pregnancy. In cases of habitual abortion microscopic examination showed the presence of extensive thrombosis within the intervillous spaces of the placenta. Small doses of chlorate of potassium would appear either to reduce the coagulability of normal blood or to neutralise the effects of some form of toxæmia which favoured thrombosis.

Dr. H. OLIPHANT NICHOLSON read a paper on a case of Eclampsia treated by Large Doses of Thyroid Extract He recommended the use of thyroid extract as a prophylactic in the pre-eclamptic state, giving it in small doses of from five to 20 grains each day, the main object of the treatment at this stage being to re-adjust the processes of nutrition in such a manner as to complete more fully the metabolism of nitrogenous substances. In actual eclampsia thyroid extract was a valuable remedy, but it must be given in large doses before good effects might be apparent. The urine might be greatly diminished or suppressed and the really essential aim of any method of treatment was to get the kidneys to secrete again. In eclampsia the condition of the arteries and arterioles was one of profound constriction with resulting rise in blood pressure. Vaso-dilatation was the principle of treatment indicated. To induce vaso-dilatation very large doses must be given, 30 or 40 grains of the thyroid extract, and a second dose of from 20 to 30 grains might be required in six or eight hours if there were no evidences of improvement. A state of thyroid intoxication must be induced as rapidly as possible. When thyroidism was produced the renal arteries became relaxed and the secretion of urine commenced. The combination of morphine and thyroid extract was most successful as a means of re-establishing diuresis; morphine must also be given in good doses, as half a grain hypodermically. Dr Nicholson then detailed a case treated by morphine and thyroid extract in which the patient made a good and rapid recovery.

These papers were discussed by Professor SIMPSON, Dr. D. BERRY HART, Dr. JAMES RITCHIE, Dr. BALLANTYNE, Dr. J HAIG FERGUSON, Dr. H M. CHURCH, Dr. W. FORDYCE, Dr. GIBBONS of Boston, and the PRESIDENT.

Dr. FOTHERGILL and Dr. NICHOLSON replied.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Dec. 3rd, Dr. W. Winslow Hall, the President, being in the chair.—Mr. C W Mansell Moullin opened a discussion on the Present Treatment of the Enlarged Prostate.—Mr. G. Buckston Browne thought that the satisfactory or unsatisfactory progress of a catheter case depended largely on the aseptic care used. Moreover, a distended bladder must be only gradually emptied. He could not agree with Mr. Moullin that after two years of catheter life the bladder lost its contractility. 11 years ago he performed a suprapubic prostatectomy on a patient who had used a catheter for 20 years. No catheter had been required since, the bladder acting perfectly. He was glad that Mr. Moullin only spoke of partial removal of the prostate; the prostate, being actually part of the bladder and part of the urethra, had never been removed in its entirety and never would be. Partial removal of the prostate, as performed now, was McGill's operation, and while too dangerous to be a routine operation was perfectly justifiable in certain extreme cases.—Mr. P. J. Freyer, who exhibited several specimens which he had removed entire in their capsules, said that antiquated and useless operations based purely on theoretical considerations were happily passing rapidly into the limbo of forgotten things. He was surprised that Mr. Moullin had made no reference to his (Mr. Freyer's) operation. He was quite satisfied with the progress which this operation had made in the last two and a half years. No operation was attended by more completely successful results and the mortality, considering the age and condition of the patients, was very small. It had also been proved that there was no such thing as atony of the bladder in connexion with prostatic enlargement, as in no instance had a patient failed to regain complete power of natural micturition. It was absurd to talk of McGill's operation as similar to his. No specimen of an entire prostate resembling those he exhibited had ever been placed in a museum before the date when his operation was placed before the profession. He believed that Mr. Shattock confirmed his views that the capsule was removed with the prostate. This, however, was a question of merely academic interest. Mr. Freyer's operation, while attended by a small mortality, gave complete and permanent cure of all the symptoms.—Mr. H. T. Herring said that the only cases that called for treatment were those that interfered with the function of micturition. He did not agree that the disease was markedly progressive or that bad symptoms must necessarily follow the use of instruments. Such symptoms did not arise from the prostate but from contamination of the urine with micro organisms The symptoms were rarely if ever increased by the habitual use of a sterile catheter. Mr. Herring denied that it was impossible for a patient to keep himself surgically clean —Mr. J. G. Pardoe considered that in the case of very aged men with tolerant bladders catheterism was the treatment of choice. As regards the loss of the expulsive power of the bladder he had never seen this after complete removal of the prostate in patients in whom catheter life had lasted for from six months to 16 years. As regards asepsis in catheterism [illegible] sibility in the large class of [illegible] work to perform for their [illegible] unable to procure assistance [illegible] the treatment of prostatic obstruction at present carried out was unsound and not based on sound pathology. Most symptoms were due to secondary contamination by micro-organisms introduced from without. Symptoms due to prostatic disease *per se* were those of slight difficulty and frequency of micturition, all other symptoms being due to cystitis, generally caused by dirty catheters, and occasionally arising from the posterior urethra where micro-organisms had remained after an attack of gonorrhœa. Treatment must therefore be directed first to the prevention of a posterior urethritis or to its cure; and secondly, to the prevention of chronic cystitis caused by dirty instruments. An instrument invented by Mr. Herring rendered catheterism practically safe —Dr. Horace Manders said that in his experience elderly men reduced to the constant use of the catheter did not show such universal tendency to sink and to die from sepsis. He had found that certain drugs, like salol, helped to prevent sepsis. He thought that male nurses ought to be more impressed with the importance of sterilisation and he did not agree that sterilisation could only be properly effected by boiling. The careful and scientific use of the catheter had prolonged many valuable lives, but a large number of cases could only be benefited by a total removal of the prostate —Mr. Mansell Moullin replied on the whole discussion.

DERMATOLOGICAL SOCIETY OF LONDON.—An ordinary meeting of this society was held on Dec. 9th Mr. Malcolm A. Morris being in the chair.—Mr. Morris showed a man in whom severe Lichen Planus of the Legs had developed after prolonged mental worry. The disease appeared nine months previously to exhibition upon the front of the ankles and crept gradually up the legs to the knees, assuming the hypertrophic type. Within the last few months the disease had also invaded the mucous membrane of the mouth.—Dr. T. Colcott Fox showed a child, aged ten months, suffering from Sclerema Neonatorum. The child was the youngest of 12 children, of whom nine were still living; he had suffered from no particular disorder at birth but had always been small. At the age of three months he had been taken to hospital on account of wasting and it was then pointed out to the mother that the skin of the trunk, especially the abdomen, was thickened and infiltrated. When shown the sclerema was gradually resolving and the skin gave a very peculiar sensation to the hand, some parts feeling thin and depressed, probably the normal parts, while others still gave the hard infiltrated impression. Dr. Fox suggested [illegible] of the presence of a slow septic [illegible] Penrose showed a case of Rough [illegible] r and a half years, coming on after a bad attack of Broncho-pneumonia. The patient had been tested on two occasions with tuberculin but without producing any reaction. Dr. Penrose said that he was familiar with the condition in tuberculosis but that this child was evidently free from the disease.—Dr. A. Whitfield said that the condition was known as pityriasis tabescentium and that it sometimes occurred in all wasting diseases, even in adults. He regarded it as a sign [illegible] t it was probably due [illegible] eir full cycle and conse- [illegible] of scales and follicular horns.—Dr. J. H. Sequeira showed: 1. A woman with a widespread Lupus Erythematosus over the head, the face, and the back. There were no history of tuberculous disease in the family and no evidence of it in the patient, but, on the other hand, there was the association with albuminuria which he had already recorded in several other cases. 2. A woman who had contracted Syphilis nine years ago and had for the last three years been affected with discoid patches and sheets of red infiltrated and œdematous eruption over the face and scalp. The eruption closely resembled seborrhœic eczema and he believed it to be a mixed eruption of syphilis and seborrhœa.—Dr. J. M. H. MacLeod showed a boy, aged 14 years, who had had an eruption which was almost certainly a local tuberculosis affecting the skin over the two inner left metacarpals and the ulnar side of the hand. The disease had existed since the age of 18 months and had greatly improved under treatment with radium.—Dr. E. G. Graham Little showed a man suffering from a small patch of Scleroderma one inch in its vertical and half an inch in its horizontal diameter, situated almost exactly in the centre of the hairy margin over the forehead. The disease existed nowhere else and had only developed four months ago. The diagnosis from lupus erythematosus was somewhat difficult.—Dr. S. E. Dore showed: 1. A girl with Ringworm of the Nails, in which the infection seemed to have occurred from the posterior fold into the matrix, only affecting the free margin later. Several nails were affected and the disease was of unusually rapid onset, having only existed two months 2 A man with a very widespread Pityriasis Versicolor affecting the whole of the trunk, the arms down to about halfway between the elbows and wrists, and the backs of the knees. The man was a profuse sweater —Dr James Galloway showed (1) a case of Rupioid Psoriasis and (2) a woman, aged 37 years, who had been affected with Scleroderma over the region supplied by the right supra-orbital for the last 20 years. It had gradually involved also the region round the right ala nasi and the inside of the nose. Now she had deafness especially affecting the left ear and this was found to be due to otosclerosis of the primary type.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Dec. 4th, Mr Charters J. Symonds, Vice-President, being in the chair.—Sir Felix Semon described a case of Epithelioma of the Larynx in which operation had been twice performed by thyrotomy and resection of crico thyroid membrane. The patient was a man, 58 years of age, who had suffered for a long time from albuminuria and chronic bronchial catarrh and had become quite aphonic. Examination revealed the presence of irregular nodular outgrowths on the anterior parts of both vocal cords. The probability of the growth being malignant, owing to the age of the patient, operation was decided on. On thyrotomy being performed the whole of the anterior and lateral walls of the larynx in the region of the vocal cords was found to be a mass of disease. This was removed together with the whole crico-thyroid membrane which was involved. The thyroid cartilage was found not to be affected. On microscopical examination the growth proved to be a squamous-celled carcinoma. The patient made a good recovery but two months after began to suffer from breathlessness and on laryngoscopic examination a greyish mass of what appeared like granulation tissue was seen projecting into the lumen of the larynx. The wound was reopened and it was found that recurrence had occurred on both sides of the middle line in front. The soft parts were removed from the thyroid cartilage, together with a U-shaped piece of the laryngeal framework and a small portion of the upper part of the trachea. The patient made a good recovery and had so far remained free from fresh recurrence. The case was noteworthy as illustrating first that chronic albuminuria and chronic bronchial catarrh were not necessarily contra-indications to radical operations of this kind; secondly, that the disease was very much more extensive than appeared on laryngoscopic examination; and thirdly, that if the disease extended beyond the precincts proper to the larynx the danger of recurrence was much greater.—Mr. Charters Symonds showed a man, 30 years of age, two and a half years after operation for Traumatic Rupture of the Trachea. There was an irritating cough which was relieved on the fifth day after the accident by the expectoration of a slough. No cartilage was found in the slough. About a month later he began to breathe with difficulty and stridor. An operation was advised with a view to removing the obstruction. On dividing the trachea in the median line the third and fourth rings were seen to be injured, one was broken and bent inwards; they had been also separated so that the trachea appeared lengthened and sharply bent inwards. The deformity was partly corrected by removing a part of the cartilage and sewing the adjoining rings together The sutures were placed so as to evert as much as possible the indented wall. The trachea was not closed. The wound was covered with gauze. A tube was not used. The patient made a rapid recovery and had suffered from no inconvenience since.—Dr. James Donelan showed a specimen and temperature chart from an inoperable case of Epithelioma of the Larynx in a man, 45 years of age, undergoing treatment by Schmidt's serum. There had been no rise of temperature and but slight constitutional disturbance. The local reaction had been marked and the growth had become decidedly smaller —Dr. H. Tilley showed a case of Complete Nasal Obstruction on the Right Side due to Chronic Dental Abscess arising from the roots of the incisor tooth and forming an external fluctuating swelling below the right nasal bone. When first seen the entrance to the right nasal cavity was observed to be filled by a fleshy mass resembling in its contour a much enlarged anterior extremity of the inferior turbinal but it was more resistant than the latter and did not appreciably diminish under the influence of cocaine. An adhesion bound it to the nasal septum. Puncture of the swelling internally by means of a hollow needle was followed by the discharge of a dark serous fluid containing cholesterine crystals. Under general anæsthesia the anterior end of the right inferior turbinal was removed and also two "dead" incisor teeth. The patient made an uninterrupted recovery.—Dr. H. Lambert Lack showed a man, aged 60 years, who had undergone operation six months previously for Epithelioma of the Epiglottis, Glosso Epiglottic Fossa, and Base of the Tongue with enlarged Glands on both sides of the neck. The cervical glands had been removed and also the primary growth (by subhyoid thyrotomy) at one operation. So far there was no recurrence.—Dr. J. Dundas Grant showed a case of Pharyngomycosis.—Cases and specimens were also shown by Major F. O'Kinealy, I M S, Dr. Scanes Spicer, Mr. F. Hunter Tod, Dr. E. Cresswell Baber, Dr. StClair Thomson, Dr. H. J. Davis, and Dr. G. C. Cathcart.

LIVERPOOL MEDICAL INSTITUTION.—The second meeting of the session of the Pathological and Micro scopical section of this society was held on Dec. 10th, Dr. R J. M. Buchanan being in the chair.—Dr. K. A Grossmann showed sections and lantern slides illustrating a case of Multiple Conjunctival Papilloma. The growths consisted of branched processes of the conjunctival stroma covered by many layers of epithelial cells.—Mr. W Thelwall Thomas showed sections of a Myeloid Tumour of the Lower Jaw removed from a patient aged four years; also an Adenochondroma of the Submaxillary Gland; a Ring of Thrombosed Hæmorrhoids removed by Whitehead's operation; and specimens illustrating Cystic Mastitis with Intracystic Papillomatous Growth and Fibro-sarcoma of the Abdominal Wall.—Dr. W. B. Warrington exhibited a large Blood Clot which had been found between the liver and the diaphragm of a patient suffering from Chronic Interstitial Nephritis. The hæmorrhage was not traced to any particular vessel and appeared to have been due to capillary bleeding from the peritoneal vessels.—Mr. Richard Williams and Mr. E. M. Stockdale showed sections of an Endothelioma of the Retina and of a Rodent Carcinoma of the Eyelid.—Mr. Hugh E. Jones and Mr. Stockdale exhibited sections of a Melano-sarcoma of the Choroid and of a Pseudo glioma of Inflammatory Origin.—Mr. Stockdale also showed a Liver with a rudimentary but lobulated left lobe.—Mr. A. W. Riddell showed a specimen of Radium prepared by Sir W. Crookes as a microscopic slide and known as the spinthariscope; under a half-inch objective and an ocular × 5 it showed the flashes only; with the eye-piece lens in addition the sparking was also seen.—Dr. Buchanan showed coloured illustrations of an Empyema Cavity, of a Heart with Aortic Disease, and a Brain with Cerebral Hæmorrhage. Dr. Buchanan also showed Films of Blood containing polychromatophilic red cells and discussed their relation to pernicious anæmia.—Dr. Warrington gave a short account of the Symptoms and Diagnosis of Combined Sclerosis of the Spinal Cord and illustrated the anatomy of the disease by preparations which had been made by Dr. J. T. Collier. Dr. Warrington considered that the symptomatology and anatomy of the disease had now been sufficiently defined to consider it a distinct disease with a recognised course and stages.—Dr. Glynn recalled the fact that Dr. Pierre Marie had described in his "Leçons sur les Maladies de la Moelle" a somewhat similar condition associated with combined degenerations of the cord which he attributed to vascular changes. The situations in which the sclerotic changes took place pointed to this vascular origin —Dr. A. S. F. Grünbaum thought that the fact that the grey matter escaped in the course of the sclerotic changes indicated that the vascular theory of the disease could not be sustained.—In the discussion of the specimens the following members took part: Dr. Buchanan, Dr. E. E. Glynn, Dr. Grünbaum, Mr. A. P. Hope Simpson, Mr. F. C. Larkin, and Mr. K. W. Monsarrat.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 1st, Mr. G. H. West Jones, the President, being in the chair.—Mr. S. Snell showed the following cases: 1. A boy (a file cutter), aged 15 years, with Optic Atrophy from Lead Poisoning. 2 A woman with Monocular Proptosis and Graefe's sign; there was no enlargement of the thyroid or tachycardia. 3 and 4 Two sisters one with Coloboma of the Iris and Choroid in each eye and the other in whom one eye only was affected. Reference was made to a boy, at present under observation, with double microphthalmos, coloboma of the iris and choroid in one eye and the remains of pupillary membrane in each eye. 5. A well-marked case of Diabetic Retinitis, with diabetes of long duration. 6. A woman with marked Albuminuric Retinitis. 7. An instance of Extreme Convergent Strabismus in a man. 8 Trachoma in an alien.—Dr. George Wilkinson showed two cases of Syphilitic Lesions of the Auditory Meatus.—Dr. A. J. Hall showed the following cases: (1) Exophthalmic Goitre; (2) Tertiary Syphilitic Eruption of the Legs; (3) Favus; and (4) Congenital Syphilide.—Mr. Richard Favell showed specimens of Tumours of the Uterus.—Dr. A E. Naish showed a case of Hæmophilia with hæmorrhage under the right iliac fascia. The patient was a boy, aged 17 years. The ankles, knees, and elbows had been frequently affected since the age of five years. The left knee was the seat of extensive osteo arthritic changes with enlargement of the bones and fixation in a flexed position. A large hæmorrhagic effusion had appeared suddenly in the right iliac fossa, accompanied by pain in the corresponding hip-joint. This mass had now completely disappeared, leaving the psoas muscle firm and thickened. The patient was the eldest of a family of four boys, three of whom suffered from the disease. One brother had died from a minute cut on the lip. His mother suffered from hæmophilia of a mild type.—Dr. Hall read a paper entitled "Some Remarks on Sudden Death," illustrated by pathological specimens He referred to the different conditions under which sudden death, apart from violence, poison, and drowning, occurred, and the difficulty of framing a definition which would cover such cases. Even if the term "*unexpected death*" were used it left out many cases. Specimens were shown illustrating various causes of sudden death, e g, pulmonary embolism, ruptured heart, ruptured aneurysm, meningeal hæmorrhage from cerebral aneurysm, syphilitic fibrosis of the heart, and pontine hæmorrhage. Reference was also made to sudden death in which nothing was found post mortem to account for it; pneumonia in the aged apparently of a mild type was also mentioned as dangerous, also alcoholism in women, and particularly the taking of strong purgatives by old people.

EDINBURGH ROYAL MEDICAL SOCIETY.—A meeting of this society was held on Dec. 11th, Dr. H. D. Shepherd being in the chair.—Dr. H. H. Littlejohn gave an address, illustrated by numerous statistical tables, on the subject of Suicide. Confining his attention chiefly to European countries he pointed out that suicide was more prevalent in central Europe than in the north or south. Saxony showed the largest number of annual suicides—viz., 392 per 1,000,000 living; Ireland, at the opposite extreme, had only 17. A curious fact was that the winter months were not those in which most suicides took place—May and June being the worst months in this respect. Suicide was more common in men than in women in the proportion of three to one, and the modes of death varied in the two sexes—women as a rule choosing those methods which were least disfiguring to the person. As regarded occupation, soldiers as a class gave far and away the greatest proportionate numbers of suicides. That the constant presence of means to the end was an important factor in determining a person to commit suicide, as in the case of the soldier, was shown also by the large number of chemists and medical men who perished by their own hand. An alarming fact was the increase in the number of suicides within recent years, an increase which was proportionately much greater than the increase in population.—Dr Littlejohn was heartily thanked for his address. —Dr. T. W. E. Ross showed a specimen of a case of Mediastinal Tumour in a boy, aged 15 years. The patient had a history of thoracic distress of only two months' duration. The tumour, which occupied almost the whole of the left pleural cavity, presented the appearance of a lymphosarcoma.—A dissertation on the Treatment of Cardiac Disease by Dr. A. B. Ross was read in his absence by Dr. H. J. Dunbar.

ULSTER MEDICAL SOCIETY.—The second general meeting of this society was held on Dec. 3rd at the Belfast Medical Institute.—Dr. W. M. Killen showed a man in whom for a considerable time the diagnosis lay between Cerebral Abscess from old Ear Disease or Tumour. The history of the case and the beneficial effect of iodide of potassium pointed in the direction of a tumour.—Mr. A. Fullerton showed a child the subject of Acquired Syphilis, the chancre being on the chin. He also exhibited a skiagram showing a Coin impacted in a Child's Œsophagus which he successfully removed by cutting down on the gullet and a skiagram of a Transverse Fracture of the Shaft of the Humerus treated by operation.—Mr. Robert Campbell read a paper on the Radical Cure of Hernia in Infants and Young Children. He had operated on 114 cases at ages varying from three weeks to ten years without a single death. There were 11 of them strangulated (two as early as three weeks). No recurrences took place and as to complications two rickety children had slight bronchitis, one wound suppurated and the stitches had to be removed, and in one case some blood clot appeared and one stitch had to be taken out.—An interesting discussion followed.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Dec. 9th, Dr. E. S. Reynolds, the President, being in the chair.—Dr. I Walker Hall and Dr. W. H. Brazil described the appearances of a Proliferative Cyst-adenoma occurring in connexion with the liver of a child, aged six and a half years. The tumour gave no symptoms during life. It was [illegible] surface of the liver and displaced th[illegible] lateral border. In structure it c[illegible] containing cysts lined by cubical or columnar epithelium It was in a condition of active proliferation, was entirely extrahepatic, and probably arose from aberrant bile ducts Several small tubes passed from the right hepatic duct to the substance of the tumour. These were found to consist of fibrous tissue in which were observed definite lumina lined by columnar epithelium.—Dr. Moore showed specimens of Cystic Disease of the Liver and Kidneys.—Other preparations were shown as card specimens and included a demonstration of Various Methods of staining Nerve Tissues.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The monthly meeting of this society was held on Dec. 9th at Bolingbroke Hospital, Mr. E. F. White, the President, being in the chair. Notes of interesting cases were read as follows: Mr. H. Stanley Turner, a case of Middle-ear Disease; Dr. M. Mackintosh, a case of Abscess in the Lung; Dr. Donald F. Shearer, two cases of Loss of Power in the Right Leg; and Mr. A. G. Everard, a case of Scarlet Fever occurring in a patient for the fifth time. Mr. Eber Candwell showed a case of Empyema, a case of Tracheotomy for Laryngitis, a case of Perforating Ulcer of the Foot, and a case of Colles's Fracture. Mr E. W. M. Hearn exhibited a case of Spina Bifida in a child, aged 30 hours, and a case of Ovarian Tumour in a girl aged nine years.

Reviews and Notices of Books.

First Report of the Trypanosomiasis Expedition to Senegambia (1902) of the Liverpool School of Tropical Medicine and Medical Parasitology. By J. EVERETT DUTTON, M B., B Ch. Vict., and JOHN L. TODD, B A., M D, C M. McGill. With Notes by H. E. ANNETT, M.D., D.P.H. Vict., and an Appendix by F. V. THEOBALD, M.A. Published for the University Press of Liverpool by Longmans, Green, and Co., London. 1903. Pp 56. Price 10*s.* 6*d.*

THE subject of trypanosomiasis has lately attracted considerable attention in consequence of the investigations recently made in Uganda as to the causal relationship between trypanosomes and sleeping sickness. In 1901 Dr. J. E. Dutton found these organisms in the blood of a European who was suffering from an illness characterised by a peculiar combination of symptoms. The clinical picture presented was one which might be confounded with that of a tropical disease. Before the details of this case were published in the "*Thompson Yates Laboratories Report*," May, 1902, a trypanosome was found in a blood film taken from a native child in the Gambia, and the discovery of a second case of human trypanosomiasis made it probable that the first was not altogether a curiosity. The committee of the Liverpool School of Tropical Medicine realised the possible importance of this new parasite as a cause of disease and with characteristic energy despatched an expedition to Senegambia to make further investigations in the subject and the report of the members of that expedition—Dr. J. E. Dutton and Dr. J. L. Todd—now lies before us.

In the introduction we are informed that in this report only a very small portion of the work done in the Gambia on trypanosomiasis is described; there is sufficient, however, to form most interesting and instructive reading. The first section deals with Human Trypanosomiasis. An attempt was made to ascertain the distribution and prevalence of the parasite. The blood of no less than 1043 persons was examined but trypanosomes were only found in six instances. The investigators, however, are convinced that the percentage given by these figures is smaller than is actually the case. Their reasons for holding this opinion are the following: (1) many cases certainly escaped identification both because of the scanty numbers in which the parasites were seen in the cases examined and because of the periodicity of their absence or presence in the peripheral circulation; and (2) the majority of the natives examined were apparently healthy children and young adults who could be persuaded by small bribes to allow their fingers to be pricked; thus suggesting that adults are more liable to infection than children. The clinical symptoms yielded by the presence of the trypanosomes revealed no marked constant characteristic.

The next part of the report is concerned with Equine Trypanosomiasis. The first trypanosome which Dr. Dutton and Dr. Todd found while in the Gambia was in the blood of a horse and this is the only animal in which they were able to distinguish a pathogenic trypanosome. Out of 36 horses examined ten were found to be infected. From the careful inquiries made the following conclusions were arrived at: (1) equine trypanosomiasis in the Gambia is a very chronic disease; (2) it occurs throughout the colony and is possibly more prevalent near the river, especially during the rainy season; and (3) cattle and other domestic animals are not known to suffer from the disease.

Although a positive diagnosis of trypanosomiasis could only be made by a demonstration of the parasite, either by microscopical examination of suspected blood or by inoculation of that blood into unaffected animals, in several cases the condition was suggested by the listless expression of the affected animal and by the slight rise in temperature which was always present. Attempts to transmit trypanosomiasis from infected to healthy animals were uniformly negative. As the "results of inoculation of the Gambian human and equine trypanosomes in experimental animals" Dr. Dutton and Dr. Todd are inclined to believe that these organisms are not the same species but further experiments are necessary before a definite result can be arrived at. Some interesting observations are recorded as regards other forms of flagellata found in Senegambia.

LIBRARY TABLE.

Guy's Hospital, 1724–1902: A Tribute to its Founder and a Record of its Work. Illustrated. London: Ash and Company, Limited. 1903. Pp. 58. Price 2*s.* 6*d.*—In commenting upon this interesting book with its admirable pictures of life in the hospital we cannot do better than quote the first words of the preface as follows: "This book is sent forth in the hope that it may help to make better known the peculiar virtue and charm, the vastness and importance of the work, and the present grave wants of the hospital founded by Thomas Guy in his lifetime. Perchance it may discover a Thomas Guy of the twentieth century." When reading this statement we can hardly help picturing the gentle dove sent forth from the ark in the hope of finding solid ground or the brave emissary sent forth in search of help by a perishing band of once prosperous explorers. The book concludes with a short and interesting explanation of the present grave financial necessities of the hospital which we believe will be new to some at least of the younger generation. We can only give extracts from this well-worded account. From 1724, and for 160 years, this great foundation and its ministrations were an absolutely free gift to the people. But the time came in the early eighties when the disasters which had overtaken British agriculture fell upon the estates which represented the founder's endowment. With overwhelming rapidity, almost without warning, the income derived by the hospital from its rents went down to almost one-half. Here the very prosperity of the hospital in the past became a source of weakness. It had no list of donors, no annual subscribers; few, if any, wills contained provisions in its favour. Guy's, in short, had yet to learn the very A, B, C of how to beg. The amount asked for (£100,000) in 1886 was gladly given but by the year 1895 this was exhausted. The governors appealed again and Mr. Gladstone made the needs of the hospital quiver in the ears of the people. Amongst those who responded was his present Majesty King Edward VII. who publicly identified himself with the cause, became president of the hospital, inaugurated a re-endowment fund, and worked strenuously for its success. It is the simple truth that His Majesty's gracious and effective action was the salvation of the case and its memory will endure so long as Guy's Hospital endures. Disaster was stayed and an era of hope and progress began but always to the accompaniment of harassing financial strain. Over and above the struggle for daily bread came the demand and necessity for heavy expenditure on the permanent works and improvements; and thus, while Guy's Hospital had never done a greater work or done it more effectively than in 1902, the close of that year witnessed the hospital heavily indebted on capital expenditure and its assured income dangerously small. The last paragraph, we think, is worth quoting *in extenso*, as follows: "Yet the spirit of Charity is not dead. In this great metropolis, whose vastness hides suffering from view and deadens the sense of responsibility, that spirit, indeed, tends to slumber; but it will answer to a true, clear call. And so let these last words be the expression of a fervent hope, a firm trust, that old friends will be reanimated and new friends found in the days that are with us, to free from care Thomas Guy's glorious foundation, that sure refuge whither, through the long years since 1724, the poor and afflicted have turned for sympathy and healing like as unto a great rock's shadow in a weary land." We can only say that if this book does not find another Thomas Guy it ought to and we hope it will; in fact, if we may say so, Guy's seems not only to have learnt A, B, C but also considerably further down the alphabet.

Traité des Urines: Analyse des Urines considérée comme un des Éléments de Diagnostic. (A Treatise on Urines: the Analysis of Urines considered as one Element of Diagnosis) By Dr. E. GÉRARD. Paris: Vigot Frères. 1903 Pp. viii.–492. Price 7 francs.—This book is a very practical work which should be found useful to practitioners of medicine. That a careful analysis of urines both in health and disease can throw light upon many of the problems of disease there can be no doubt and Dr. Gérard gives a very full account of the many methods which are employed in analysis. The book is divided into three parts, the first of which treats of the analysis of normal urines and the second of the analysis of the urine as secreted in varying pathological conditions. Albumins are treated of first and then follow the sugars, acetones, blood, and the presence of digestive substances, such as bile, leucin, and tyrosin. Chapter XIII. deals with urinary sediments and thence to the end of the part the author speaks of the various modifications brought about in the normal constituents of the urine by pathological conditions. In Part III. the clinical urology of various diseases is dealt with. Altogether the book should be found of great use.

Practical Text-book of Midwifery for Nurses. By ROBERT JARDINE, M.D. Edin. Second edition. Edinburgh: W. F. Clay. 1903. Pp. 284, with 30 Illustrations. Crown 8vo. Price 6*s.*—The second edition of this work has been carefully revised and many alterations have been made. We notice that the author has left out the words "for students" in the title. In this he has been well advised since, as we pointed out in our notice of the first edition, the book is hardly a suitable one for the use of students. A new chapter has been added on Accidents to the Child during Delivery: Abnormalities and Diseases of the New-born Child. This contains a good account of the various accidents and ailments that a nurse may be required to recognise. The book should be of value to women intending to practise as midwives and is a good example of its class.

Essays and Notes on Hydrotherapeutics. By RICHARD METCALFE London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1903 Pp. 254. Price 3*s.* 6*d.* net.—Mr. Metcalfe, we gather from the appendix to his book and from the illustration which forms the frontispiece of the appendix, is the proprietor of a hydropathic establishment at Richmond. Hydrotherapeutics, like every other form of medication, have their uses when properly directed by an intelligent medical man. Mr. Metcalfe's views on the pathology of scarlatinal dropsy show that he at all events does not come under this category. On p. 16 we read: "Scarlatina being an eruptive disease of the skin obstructs the escape of the perspiration and causes the fluid to accumulate in the system. The kidneys will for a time succeed in relieving the patient. But if the skin is not speedily restored to its normal action dropsy is inevitable." The value of clean water to drink, of cleanliness, and of wet packs in certain febrile and other diseases is now fully recognised by the medical profession and although we can allow that hydrotherapy has its uses Mr. Metcalfe is evidently not the man to advise as to them.

Who's Who, 1904, and Who's Who Year Book, 1904. London and Edinburgh: Adam and Charles Black. Price 7*s.* 6*d.* and 1*s.*—This useful book of reference is published for the first time this year in two parts. The biographical portion appears by itself, while the tables of general information form a separate and much slenderer volume. "Who's Who" has now become indispensable to the furnishing of every editorial desk. The times in which we live make it necessary that accurate information should be quickly available about all sorts and conditions of men. We in the office of a professional newspaper feel this and our feeling is shared by the thinking world. Not so very long ago, say 25 years, we required information about few people that we could not obtain from the Medical Directory. Medicine has now enlarged its borders. Public health governs public policy, tropical medicine is a matter of imperial policy, the work of the engineer and the electrician dovetails with that of the chemist and the sanitarian, and the medical journalist must on occasion be expected to know the status and the past record of men who have distinguished themselves in any branch of their various provinces of life. We turn to "Who's Who" for assistance and it is easy to see that our fellow editors do the same, whatever the general or particular lines of their organs. Of the actual biographies, which form the compilation we thus commend, there is not much to be said when we remember that they are for the most part furnished by their subjects. The larger biographies do not necessarily set forth the careers of the greater men, while the confidences given to the public by some of the writers are laughable. Such blemishes do not, however, detract from the utility of the book, for it is always easy to distinguish the really important people from the others, even though the claims of the others to consideration are furnished in meticulous detail.

Manual of Diseases of the Eye. By CHARLES H. MAY, M.D., Chief of Clinic and Instructor in Ophthalmology, Columbia University, New York. Third edition, revised. London: Baillière, Tindall, and Cox. 1903. Small 8vo, pp. xv.-408, with 275 illustrations. Price 8*s* 6*d* net.—This edition of Dr. May's work has been revised without being enlarged. The chapters correspond with those that other authors have found convenient to divide the subject of ophthalmology into, as the mode of examination of the eye, the theory of the ophthalmoscope, the various diseases of each part of the eye and of its appendages, the refraction of the eye and the errors to which it is liable, the disturbances of motility, and ocular therapeutics. The accounts of the several affections to which the eye is liable are briefly but clearly and correctly given and no space is wasted in unnecessary details respecting the mode in which remedies should be applied or operations performed. The student is supposed to be familiar with the details of minor surgery. Recent methods are not neglected as, for example, the use of protargol and the subcutaneous injection of solutions of corrosive sublimate in cases of refractory ulcers of the cornea so strongly advocated by the late Professor Panas. The connexion between the retinæ, the fibres of the optic nerves and tracts, and the cerebral cortex is well given. The illustrations though numerous are a little coarse, especially in the case of those representing the normal fundus of the eye. The manual will prove a useful book for students.

The Living Temple. By J. H. KELLOG Battle Creek, Michigan, U.S.A.: Good Health Publishing Co. 1903. Pp. 568. Price 5*s.* 6*d.*—This work is a book on diet and hygiene written from a vegetarian standpoint. It contains some sense and a good deal of nonsense. There is no doubt that many people eat too much meat, many people drink far too much alcohol, and many people smoke too much or drink too much tea and coffee. But we do not believe that in northern climates, under modern conditions of work and society, that human beings can manage to live and to do their work upon a purely vegetarian diet. If we could all return to primitive conditions and live in Sicily or some of the South Sea Islands the case might be different. We are quite in accordance with the author as to his strictures upon modern bread made from flour which has nearly all the nutriment removed from it. It is a pity that a book which contains some really good advice should lay down counsels which cannot be followed under conditions of modern life.

Fungi, Protophyta, and Protozoa: their Relation to each Other, to Helminths, and to Disease, particularly Malarial Fever in the Tropics. By G. H. FINK, M.R.C.S. Eng., Major, I.M.S. (retired). Pp. 40 —In this little brochure the author, after referring to the work done by Laveran, Ross, and Manson in regard to the etiology of malaria, describes an outbreak of malarial fever that fell under his notice in the Bori Valley in South Afghanistan which was followed by epidemic infectious pneumonia. He attributes the outbreak to the impurity of the water and the scarcity of milk and having tested the water he was able to predict the occurrence of malarial cases in large numbers. Elsewhere he found that water swarming with mosquito larvæ was used for watering lettuces which were eaten raw and that malaria was prevalent. He also describes malarial fever in dogs and gives the modes in which spores may gain entrance into the body of these animals. Major Fink has a high opinion of the value of castor oil as a remedy in malaria. In this and other points we do not doubt his conclusions but the facts upon which he bases them are far too few and imperfectly worked out as they are here given to justify them. Finally, Major Fink should really attend to the orthography of the scientific names that he employs. Twice he spells "empusa" "empusca," and "filletia cares" is not the way to spell "tilletia caries," which, we presume, is the organism referred to

Whitaker's Almanack, 1904. London: 12, Warwick-lane, Paternoster-row.—The 1904 edition of this indispensable work contains as usual some new features. Such are a tabular history of consols and of the income tax, a special article on technical education, tables and articles bearing on the fiscal question, an account of the marriage laws of Scotland, and the laws referring to motor cars. There is also a political history of the world for 1902-03. The perpetual calendar has been struck out and its place has been supplied by a calendar for 700 years from 1752, the date of the introduction of the new style. The rest of the book is as good and as useful as ever and no higher praise can be given.

Whitaker's Peerage, 1904. London: J. Whitaker and Sons —This, we fancy, is the most complete peerage for its size that is published. The amount of information compressed within its 720 pages is enormous. The list of seats and residences now excludes all belonging to anyone under the rank of a knight and all of an official character. But the book is a worthy companion to the Almanack.

THE ETIOLOGY OF SLEEPING SICKNESS.

In The Lancet of Sept. 12th (p. 769) we drew attention to a Progress Report which had been issued by the commission which had been despatched by the Royal Society to Uganda to investigate the origin of sleeping sickness. We intimated the lines along which the inquiry had been conducted and also the results which had been already arrived at. Before proceeding to consider the further work of the commission it may prove interesting to refer to the events which led to its appointment. In 1902 Dr. G. C. Low, Dr. C. Christy, and Dr. A Castellani were sent by the Royal Society Committee to Uganda to study the disease. After some months Dr. Castellani reported that he had discovered a streptococcus which he announced to be the cause of the disease. Dr. Low and Dr. Christy were unable to come to any conclusion as to the etiology of sleeping sickness and returned home, having made certain observations as to the distribution and features of the disease. Dr. Castellani remained in Uganda in order to work out more fully the *history and nature of the streptococcus above mentioned*. The Royal Society Committee then determined to advise the Foreign Office to secure, if possible, the services of an observer of experience and proved skill—namely, Lieutenant-Colonel David Bruce, F.R.S., of the Army Medical Service, the discoverer of the blood parasite in the nagana or tsetse fly disease of South Africa. Lieutenant-Colonel Bruce, accompanied by Dr. D. Nabarro, reached Entebbe on March 16th. There they were met by Captain E. D. W. Greig of the Indian Medical Service. Dr. Castellani informed these gentlemen of the work which he had been doing, one especially interesting observation being that he had discovered trypanosomes in the cerebro-spinal fluid in five out of 15 cases of sleeping sickness. The results of Dr. Castellani's further investigations were published in No. I. of the "Reports of the Sleeping Sickness Commission," to which we referred in our annotation on Sept. 12th.

A "Further Report on Sleeping Sickness in Uganda" is now before us and bears the names of Lieutenant-Colonel David Bruce, R.A M.C., F.R S , David Nabarro, M.D. Lond , and Captain E. D. W. Greig, I.M.S. It was received on Sept. 30th, 1903. It states that in order to make it more easily understood and to prevent the necessity of constant reference to the previous "Progress Report," in certain places, not very numerous, extracts from the latter have been incorporated in the present report. It then proceeds as follows :—

> Since this further report contains a good deal of detail which may make it difficult to pick out easily the salient points, it may be well to point out at the outset that this report brings forward evidence to show :—
>
> 1. That sleeping sickness is caused by the entrance into the blood and cerebro-spinal fluid of a species of trypanosoma.
> 2. That this species is probably that discovered by Forde and described by Dutton from the West Coast of Africa and called by him *trypanosoma Gambiense.*
> 3. That the so-called cases of trypanosoma fever described from the West Coast may be, and probably are, cases of sleeping sickness in the earliest stages.
> 4. That monkeys are susceptible to sleeping sickness and show the same symptoms and run the same course, whether the trypanosomes injected are derived from cases of so called trypanosoma fever or from the cerebro spinal fluid of cases of sleeping sickness.
> 5. That dogs and rats are partially susceptible, but that guinea-pigs, donkeys, oxen, goats, and sheep, up to the present have shown themselves absolutely refractory.
> 6. T [illegible] the sick to the healthy by a [illegible] by it alone.
> 7. [illegible] and *Glossina palpalis* correspond.
> 8. That sleeping sickness is, in short, a human tsetse fly disease.

Many questions referred to in the Progress Report are elaborated in the report now under consideration. For instance, on the interesting point as to whether the so-called trypanosoma fever has any connexion with sleeping sickness the report states :—

> On the West Coast of Africa, during the past few years, trypanosomes have been found in the blood of several persons and the name trypanosoma fever has been given to that disease. The parasites have not been confined to the blood of natives, but at least three white people have harboured them. No suspicion of these being cases of sleeping sickness has been entertained by those in medical charge of them. The symptoms are different. Trypanosoma fever appears to cause little or no inconvenience to those harbouring the parasite, whereas in *sleeping sickness the disease* is a well-marked one and is invariably fatal. Can there be any connexion between the two?
>
> In March last Dr. Baker of the Colonial Service, who is stationed here, discovered trypanosomes in the blood of five natives, and Dr. Moffat, the principal medical officer, has also found them in the blood of a European.

Illustrative cases are given which go to show that there is probably a close connexion between the two diseases.

Another necessary point to determine was: "Does the blood of the general population contain trypanosomes?" On May 18th the commission received a telegram from the Royal Society, asking for statistics regarding the prevalence of trypanosomes in the general population (*a*) inside and (*b*) outside the sleeping sickness area. On a little consideration the importance of such an inquiry is seen. If the trypanosoma found in the blood of patients suffering from trypanosoma fever belongs to the same species as that found in sleeping sickness, then a larger percentage of the general population inside the sleeping sickness area should be found to harbour trypanosomes than those living in the non-sleeping sickness area. In fact, if the supposition be true there ought not to be a single trypanosoma found in the blood of persons living in a clean area. Because, if the theory that trypanosomes in the blood is merely the first stage of sleeping sickness be true, then all the cases in the non-sleeping sickness area cannot be in the initial stage, but scattered among them the observer would naturally expect to find some in the more advanced stage. In Entebbe the hut tax labourers supply ample material for such an investigation. There were some 1500 employed there and they came from all parts of the Protectorate. They remained at work in Entebbe for one month and then returned to their homes. During that time they were liable to contract sleeping sickness, but for the purpose of this inquiry natives from non-sleeping sickness areas, who had only been a few days in Entebbe, were chosen. Captain Greig also went over to Nairobi, in British East Africa, and examined 50 cases in an undoubted non-sleeping sickness area. The results of these examinations are given in accompanying lists in the report. These will be useful six months or a year hence in order to trace out and to learn the fate of the men whose blood now show trypanosomes, but who at present have no symptoms of sleeping sickness. 80 natives from the sleeping sickness area were examined, with the result that 23 were found to have trypanosomes in their blood, giving a percentage of 28 7. 117 were examined from non-sleeping sickness areas, but not a single trypanosoma was found. We agree that these results suggest that the trypanosomes found in the blood of seemingly healthy persons and in the cerebro-spinal fluid of sleeping sickness cases are identical and, further, that these trypanosomes are, in truth, the cause of the disease.

It is also natural to inquire whether any difference can be made out microscopically between the trypanosoma of sleeping sickness and that of trypanosoma fever. In the progress report it was stated that it would appear that the trypanosomes found in sleeping sickness are shorter, have chromatic dots more frequently, and the micro nucleus is situated nearer the end than in the other. Since the above was written an observation has been made which would seem to do away with any significance which the above differences in size and shape may seem to have. It is that trypanosomes from the cerebro-spinal fluid injected into the blood of monkeys become quite as long as the trypanosomes found in the blood of man, and the other differences also disappear. This would go to show that the trypanosomes merely find the cerebro-spinal fluid not as favourable for their growth as the blood and on this account are stunted.

An important series of observations was made to ascertain whether the trypanosomes are pathogenic to animals and whether any specific difference can be made out between them by means of suitable tests. A full report of the results of inoculations is given and forms a record from which valuable conclusions can be formed. The animals available for inoculation were monkeys, dogs, guinea-pigs, rats, donkeys, oxen, sheep, and goats. No animal was found which showed any marked susceptibility to the disease or in which the disease runs a rapid acute course, as is the case in nagana. The monkeys proved most useful and were injected subcutaneously, into the vertebral canal, and through the foramen magnum into the brain cavity with cerebro-spinal fluid and blood from many sources. Animals were inoculated with trypanosomes from the spinal fluid of persons suffering from sleeping sickness and from the blood of individuals who showed no symptoms of the disease. We quote an experiment from each class of case :—

> Experiment 1.—Monkey, male, pale-faced variety (*Macacus rhesus*) To note the effect of the subcutaneous injection of cerebro-spinal

fluid containing trypanosomes from a case of sleeping sickness. March 23rd, 1903. Injected 10 cubic centimetres of cerebro-spinal

The
try-
this
monkey has shown symptoms of sleeping sickness. He sits all day long with his head sunk on his chest, evidently asleep. July 10th. Since the last entry the appearance of sleeping sickness has become more marked. The animal sits still all day with eyes closed and head sunk on chest. He is extremely emaciated but has no marked signs of paresis. He can still climb into his box. As he sits in this lethargic condition the muscles of the arms and trunk frequently show marked twitching, a symptom often seen in the last stages of sleeping sickness. July 12th. Died at 11.30 A.M.

The following table shows the presence or absence of trypanosoma in the blood.—

others are in the incipient stage of sleeping sickness.

Trypanosomes were also injected into dogs, but the native dog in Uganda is not very suitable as an experimental animal. Many of them die from ankylostomiasis before the experiment is finished and this disease is so common among them that it is difficult to obtain one free from it. The conclusion arrived at from a study of the few cases under observation was that the trypanosomes of sleeping sickness and trypanosoma fever can live and multiply for some time in the blood of the dog but tend to disappear sooner or later and that they show no difference in their action on the dog. Further, it would seem that a puppy is less susceptible than an adult, just as the calf is less susceptible to piroplasma than grown-up cattle.

Accounts are also given of the effect of the injection of trypanosomes into guinea-pigs, donkeys, oxen, sheep and goats. For the results of these experiments we refer our readers to the original reports.

The question is then asked: Are we dealing with one or more than one species of trypanosoma? As has been shown, no morphological difference can be made out between the trypanosomes found in the cerebro-spinal fluid of cases of sleeping sickness and those found in the blood of persons evidently in good health. Neither can any difference be detected in their behaviour when inoculated into various animals. More experiments are required and more results obtained before this question can be answered unhesitatingly but at present the evidence distinctly tends to show that we are dealing with one species of trypanosoma and that species is probably trypanosoma Gambiense, discovered by Forde and described and named by Dutton.

The next subject dealt with is the history and distribution of sleeping sickness in Uganda. The report proceeds :—

According to Dr. R. U. Moffat, C.M.G.,[1] principal medical officer, British East Africa and Uganda Protectorates, the first cases of sleeping sickness in Uganda were reported by the Drs. Cook, C.M.S. Medical Mission, Mengo, in April, 1901. These cases came from Busoga. On Dr. Moffat's return from leave in April, 1902, he was surprised to find that the disease had become epidemic in Busoga and that it had spread into the neighbouring parts of Uganda and Kavirondo.

He is of opinion that the disease is not indigenous to Uganda, but has been imported during recent times from the Congo basin. This, he thinks, "is no matter for surprise when we consider that the opening up of equatorial Africa has led to intercommunication between countries and districts which in earlier days were absolutely cut off from each other." He is inclined to explain the first appearance of the disease in Busoga by the fact that a large number of Emin Pasha's Soudanese, accompanied by a multitude of slaves from the Congo territories west of Lake Albert were brought in and settled in Busago. Dr. Hodges, who studied the question in Busago, thinks it first broke out there in 1896. Be this as it may, the disease is now widely spread round the northern shores of the Victoria Nyanza from Buddu on the west to south of Kavirondo Bay on the east. As far as I am aware the disease has not yet entered German territory.

As the first Sleeping Sickness Commission sent out by the Royal Society made this part of the subject—the distribution of the disease—an object of special investigation, it was thought unnecessary to pursue the subject further. Full details of the work done are not at present available, but for the purposes of this report it may be stated that this disease has a remarkable distribution, being confined to the lake shore and to the islands. How wide the strip of lake shore affected by the disease is differs in different parts.

Mr. Cubitt, assistant collector, Busoga, who investigated the distribution of the disease in his district, in a report to the commissioner, dated Jinja, June 14th, 1902, says, "it would seem to be a fairly accurate statement to ma[illegible] itself to the territories adjoining the [illegible] to 20 mile radius of the coast, and [illegible] suffer in proportion to the greater [illegible] have with the people living within that radius, while in those who have no trading transactions with the people of the lake there are found no traces of the disease." In the opinion of the Uganda Prime Minister, Apolo, a strip ten to 15 miles wide would cover the affected area and any cases found further inland are imported. The numerous islands which lie near the northern shores of the lake are also the seat of the disease. Between these islands and the mainland and for several miles inland a constant interchange of commodities and intercourse between the natives takes place.

There must be some reason for this peculiar distribution. It cannot be due to a food poison, as the natives outside this narrow strip have the same habits. Then, again, if the trypanosomes are the cause of the disease, which there is every reason to suspect, the infection cannot be conveyed in food or clothes or directly from man to man, but most probably must be ca[illegible] This led the commission to ask t[illegible] Does the distribution of sleeping [illegible] of any biting insect? On the analogy of nagana a tsetse fly was suspected. But the tsetse was not supposed to be present at altitudes of 3000 feet and upwards, nor was it known to be found in Uganda.[2] A short search in the Botanical Gardens, Entebbe, disposed of these objections. A tsetse fly very similar to the one met with in the fly country, Zululand, was found in numbers. For three months we have had on an average 400 tsetse flies brought into the laboratory every day by a few native children. These flies were caught on the lake shore in the immediate vicinity of Entebbe. This gave a lead. The Prime Minister and Regents were asked to meet the commission and have the matter explained to them. They at once recognised the fly as one known to the Muganda as kivu and said that it was found along the shores of the lake[3] They were supplied with several dozen nets, killing bottles, and boxes and on their part promised to have the distribution of the fly worked out. A letter was also addressed to the Bishops of Uganda, who kindly promised to obtain information from their missionaries. Every official and missionary in the country was then sent a specimen of the tsetse fly and informed by letter as follows :—

"Sleeping sickness in many ways, is very similar to the fly disease of South Africa. It is caused by the same kind of parasite and is possibly carried from man to man by some insect as the fly disease is carried by the tsetse fly (*Glossina pallidipes*). A species of tsetse fly (*Glossina palpalis*) is also found in Uganda, especially along the shores of the lake and in the islands. It is possible that this fly acts as the carrier of the infective agent of sleeping sickness. If this is so the disease can only occur in places where the fly is found. In other words, *no tsetse fly, no sleeping sickness.*

"In order to settle this question the distribution of this fly must be carefully worked out. To assist in this would you kindly send collections of biting flies from your district and answer the following questions: (1) Is the tsetse fly (*Glossina palpalis*) found in your district? (2) In what kind of place is the fly found—marsh, banana plantation, bank of river, shore of lake, forest, bush, or open places? (3) When does it bite, during the morning, mid-day, or at night? (4) Is it numerous? (5) What animals does it bite? (6) Does sleeping sickness occur in the same place, distinguishing, of course, between imported cases and those which have been infected on the spot?

"The best way to catch the flies is by means of a small butterfly net. *They can then easily be killed by a squeeze and* placed in a small envelope with the name of the place and date of capture written on it. I may add that the natives call the fly kivu, plural bevu. It is important that the position of the place in which these tsetse flies are found should be exactly laid down. This can be done by giving the latitude and longitude in degrees and minutes or by saying how many miles it is from a known place in a westerly or S.S.W., &c., direction. Still better would it be to make a tracing of the district and on this to map out the distribution of the fly and of the sickness. It is no use trusting to report. The flies themselves must be caught and sent here for identification. The natives use the word kivu for several varieties of biting flies. If no tsetse flies are found in the district please send specimen of any of the various biting bites or insects known to the natives."

During June, July, and August some 460 collections of biting flies were sent in from all parts of the Uganda. As each package came in the contents were sorted into tsetse flies and other biting flies. If the parcel contained one or more *tsetse flies* a round red disc was stuck on a map over the locality from which the flies had been sent. If, on the other hand, no tsetse were found a blue disc was fixed over the spot. In the same way and at the same time a second map was prepared to show the distribution of sleeping sickness. That is to say, if the note on a parcel of flies stated that sleeping sickness is prevalent then a red disc was placed over the locality, and if, on the contrary, no cases of sleeping sickness were reported a blue disc was affixed. Where cases were reported to have been introduced from some other locality and to have died out without any spread of the disease in the neighbourhood, then a yellow disc was used.

It is evident that two maps so prepared should show at a glance whether the distribution of sleeping sickness and *Glossina palpalis* corresponds or not. [illegible]s (see Figs. 1 and 2) are taken from the originals. [illegible]e third the size of the larger maps and the blue [illegible] are replaced by black. On comparing these tw[illegible] *the distribution of sleeping* sickness and *Glossina palpalis* is self-evident. The disease and the fly are limited to the shores of the lake and to the islands, except in Busoga where some of the red dots are seen in the centre of the district. The fly is also seen to pass up the Nile. This is probably due to the fact that the Nile is a great broad waterway, where it issues from the lake at the Ripon Falls and may be looked upon in its physical characters as an arm of the lake. The other Uganda rivers are mere swamps full of papyrus. As it appeared important personally to examine one of these so-called rivers to discover how far the tsetse fly could be traced up their valleys one of us (Dr. Nabarro) proceeded on July 4th to explore the Katonga river. An account of this expedition is given by Dr. Nabarro as follows :—

"This expedition proceeded by canoes from Entebbe to the Island of Bussi. The tsetse fly was not sought here as it had been previously found by Colonel Bruce. Then it visited the islands Zinga and Bunjako, in both of which the tsetse fly was easily found along the shore of the lake where there was *forest and short grass.* Sleeping sickness is prevalent on all three islands. Buganga was the next place visited and here, too, the tsetse fly was found as well as large numbers of tabanidæ. Sleeping sickness is prevalent in Buganga. We left Buganga and sailed round the Katonga bay to see if there were any channel up the Katonga river but we could find none, the so-called river being a papyrus swamp about 1200 yards wide. We then went further on and landed near Magambo where forest comes down to the edge of the lake. Here, too, the tsetse flies were caught in numbers and there were several cases of sleeping sickness in the neighbourhood. From Magambo we marched across the Kibikuta river (1800 yards wide) about two miles from where it enters the Victoria Nyanza. No tsetse flies were found there. Thence we marched to the Katonga river, which like the Kibikuta is merely a papyrus swamp. The left bank of the Katonga was explored from the lake shore, close to the mouth of the river, to a point about 13 or 14 miles up the river and no tsetse flies were seen. So far as I was able to *ascertain there is no sleeping sickness* in this district.

"The return journey to Entebbe was made by road, passing through Metala Maria and Kianjia. In neithe[illegible] flies found, though stomoxys and [illegible] numbers. These two villages are situated about two to three [illegible] from the shore of the lake, which here consists of a vast papyrus swamp between the mainland and adjacent *Islands* Bunjako, Zinga, and Bussi. No tsetse flies were found [illegible] close to this swamp. There is no sleeping sickness at [illegible]a. From Kianjia we went along the main road [illegible]half miles distant), where we found no tsetse fli[illegible] sleeping sickness. We then travelled by the porters' road for ten miles, *viâ* Busami and Gabongas, and did not find any tsetse *flies* until we reached the shore of the lake at 'the ferry,' near Entebbe. Here many flies were easily caught in the dense forest that there runs along the lake shore. I was informed that there were several cases of sleeping sickness in the 'Shambas' near the lake shore, but that there were none in the interior—at Busami or Gabongas."

The main points of interest in Dr. Nabarro's account are that the fly does not proceed up the swampy river valleys and that even on the coast behind papyrus swamps it is also absent. On the map this journey is shown by a series of red dots on the islands and on the shore at the mouth of the Katonga river, and by blue dots up the river and along the shore behind the islands. The space between the islands and the mainland is one huge papyrus swamp. In order to work *out more* minutely the habits of the *Glossina palpalis*, the peninsula on which Entebbe stands was taken in detail and carefully searched for the fly. The result of this showed that the fly is only found on the shore of the lake where there is forest. This forest is thick jungle with high trees and dense *undergrowth. The fly is* never found on open sandy beaches backed by grass plains, even although there may be some small *scrub* near the water's edge. It is never found in the grass of the grassy plains, even though the grass be long and tangled. It has not been found by us in banana plantations, nor at any time far from the lake shore.

---

[1] Foreign Office Despatch, August 5th, 1902, Inclosure 2—Preliminary Notes on Sleeping Sickness by the Principal Medical Officer, June 17th, 1902. Inclosures 3 and 4—Dr. Hodges to Dr. Moffat, May 8th, 1902, and May 26th, 1902.

[2] Since the above was written I find that Mr. F. J. Jackson in a despatch to the Foreign Office, dated Sept. 27th, 1901, writes, "I may add that there is a species of tsetse fly found along the wooded portion of the lake shore here at Entebbe. It is plentiful in the Botanical Gardens."

[3] The tsetse flies found near Entebbe were sent to Professor Ray Lankester, the *director of* the *British Museum (Natural History)*, on March 25th and identified by Mr. E. E. Austen as *Glossina palpalis* (Rob. Desv.). He writes: "This is the West African species and its occurrence in Uganda is very interesting and was quite unexpected by me, though it is true that another species—*Glossina fusca*—occurs both in West and East Africa."

DISTRIBUTION OF SLEEPING SICKNESS AND GLOSSINA PALPALIS IN UGANDA

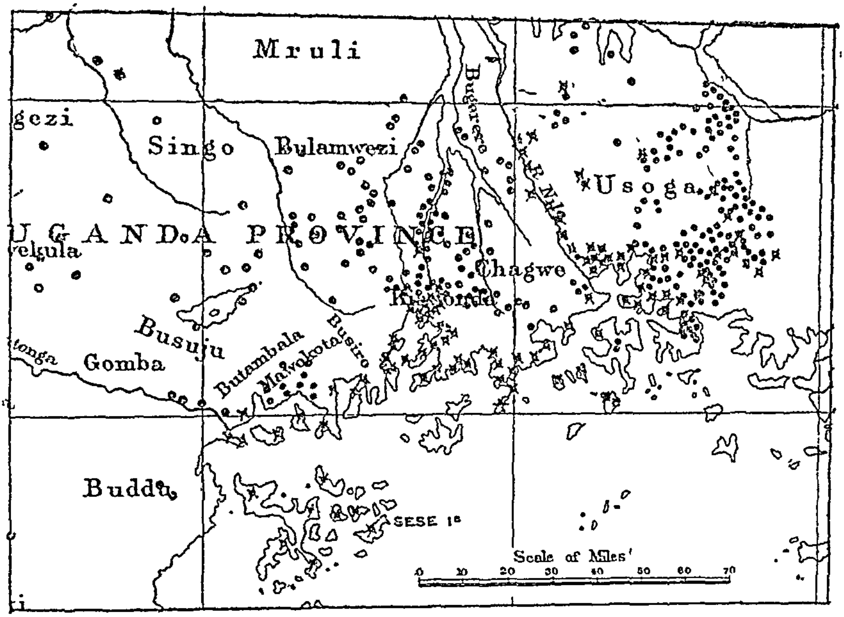

FIG 1.—The stars show the localities of the tsetse fly, the dots indicate the other biting flies

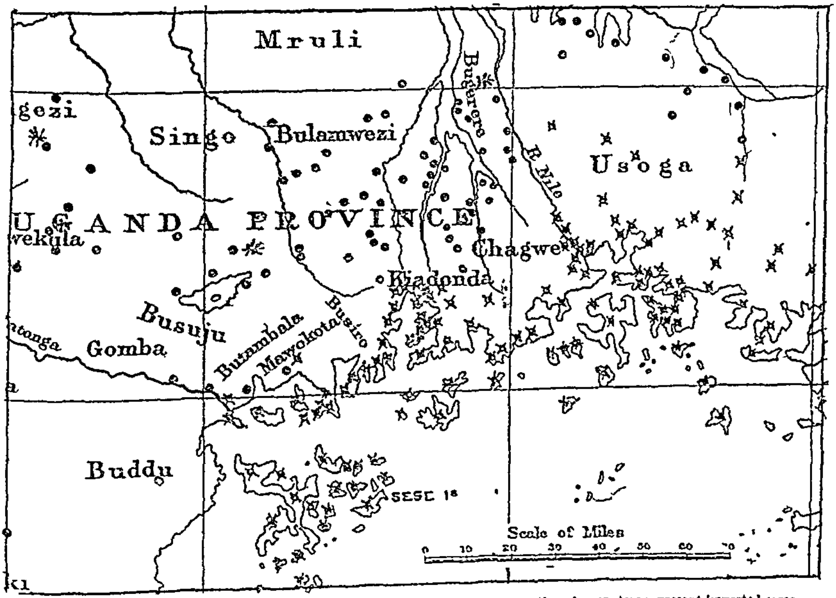

FIG 2.—The stars show the localities of sleeping sickness, the dots its absence The three larger stars represent imported cases

The habitat, then, of this fly in the neighbourhood of Entebbe is the shore of the lake where there is forest. In Uganda generally the same seems to hold good. In Busoga, on the other hand, it appears to be found inland, but what the physical characters of this province are which would account for this I have not learnt. The fly also passes down the Nile as far as Kakoge ferry some 50 miles north of the Ripon falls and it has even been received from Fajao on the Somerset Nile and from Tengri and the Achwa river, still further north and near Wadelai. It is important that the distribution of this fly should be fully worked up, but enough has been done to show that the distribution of this species of tsetse fly is, like sleeping sickness, confined to the shores of the lake and the islands. It is on the densely wooded shore of the lake that the half-naked natives of the mainland and islands meet in thousands to trade in fish, bananas, earthenware, &c. If the *Glossina palpalis* can act as a carrier of the trypanosoma of sleeping sickness, the circumstances could not be made more favourable than they are for the spread of the disease.

A series of experiments was next instituted to ascertain whether the Uganda tsetse fly (*Glossina palpalis*) can carry the trypanosoma found in cases of sleeping sickness to healthy animals. The animal chosen to carry out these experiments was the monkey. These are by far the most suitable animals to work with. They are easily procured, easily fed, and keep their health perfectly in captivity. The method used was simply to feed tsetse flies on a patient suffering from sleeping sickness and at varying intervals of time to place the same cage of flies on the monkey. The sleeping sickness patients did not seem to feel the bites of the flies, as they made no complaint or other signs of inconvenience. There were, as a rule, about 30 flies in each cage, but only those which filled themselves were reckoned as having fed. After certain details as to the methods adopted, the report continues:—

As the result of five experiments it may be considered proved that *Glossina palpalis* can convey trypanosomes from sleeping sickness cases to healthy monkeys up to at least 48 hours after feeding. We have seen that every third or fourth native in the sleeping sickness area carries trypanosomes in his blood, so that the fly has plenty of material to draw from. It may be objected that the parasites are so scarce in the blood that it is unlikely the fly will get hold of them. The same objection might be urged in regard to nagana, whose trypanosoma is probably scarcer in the blood of the wild animals than is the case in sleeping sickness. No doubt cases do occur among sleeping sickness patients, though rarely, in which the trypanosomes are fairly numerous. It is thought that they may be more numerous in the early stages when still confined to the blood than in the later stage of sleeping sickness. The observations on this point are as yet neither numerous nor exact enough to warrant any dogmatic statement.

The next series of experiments was made to find out if the ordinary wild tsetse flies, freshly caught and placed on healthy monkeys without any artificial feeding, will give rise to the disease. This is a still more important point and in this also the experiments are given in full. The flies were caught on the shore of the lake in the vicinity of Entebbe and when brought to the laboratory were immediately placed on healthy monkeys.

The following shows the results of one of the experiments:—

EXPERIMENT 94.—Monkey (*Cercopithecus* sp.). To ascertain if tsetse flies, freshly caught in the vicinity of Entebbe, are carrying trypanosomes.

May 13th, 1903. Blood examined. No trypanosomes. No malaria.

May 13th ...	Fed 31 flies.*	May 19th ...	Fed 20 flies.
„ 15th ...	„ 15 „	„ 20th ...	„ 13 „
„ 18th ...	„ 10 „	„ 21st ...	„ 16 „

Blood examined. Trypanosoma absent. Malaria absent.

May 22nd ...	Fed 20 flies.	May 25th ...	Fed 31 flies.
„ 23rd ...	„ 25 „	„ 26th ...	„ 18 „
„ 24th ...	„ 17 „	„ 27th ...	—

Blood examined. Trypanosomes *present*. Malaria absent.

* Freshly caught near Entebbe.

Three experiments (including the one we have quoted) gave positive results. To quote further from the report:—

The flies were caught in the vicinity of the hut-tax labourers' camp. These men to the number of thousands come to Entebbe and work for Government for one month in lieu of paying hut-tax. They live in rudely built grass huts near the shores of the lake, about a mile from Entebbe along the Kampala-road. Tsetse flies caught at this place and brought in cages to the laboratory have conveyed trypanosomes to three monkeys. What could be more suggestive? It is true that the trypanosoma conveyed to these monkeys may be a different species from that found in sleeping sickness, but taking everything into consideration the probabilities are that it is the same.

If this is so it would be interesting and instructive to know what percentage of the hut-tax labourers develop this disease on their return to their homes. It may possibly be an extremely small figure as these men are only exposed to the risk for a month and, as a rule, their work lies in the town where tsetse flies are never found. This is very different from the case of the natives who live all their lives on the edge of the lake and are exposed all the year round to the infection. In our opinion, if these hut-tax labourers were camped on suitable ground there would be little or no danger in their coming into Entebbe to do a month's work.

Up to the present we have received very few notices of the occurrence of cases of sleeping sickness, in non-sleeping sickness areas, supposed to have been contracted in Entebbe or on the lake shore. Five cases are reported by the White Fathers to have occurred at Kiambalangos Place, south of Hoima, and three cases in Bwekula by Mr. Lewin. These men are stated to have contracted the disease round about the Victoria Lake and have all died out without spreading the disease. Another curious case is reported by Major Harrison, K.A.R., at Nairobi, in British East Africa. The man was a bugler named Mahomed. He left Uganda in May, 1900, enlisted at Nairobi, British East Africa, on Nov. 7th, 1900, and died of sleeping sickness Feb. 18th, 1902. Dr. Wiggins also relates the case of an Askari or native policeman named Sullivan Khair, stationed at Fort Ternan, British East Africa, for two and a half years before he developed the disease. He came from Entebbe and except for a visit to Jinja, Busoga, 14 months before he died, he had not left Fort Ternan. Neither of these men set up infection among their comrades.

These cases hint at a long incubation period when the trypanosoma is confined to the blood and also to the need of the tsetse fly to act as intermediary between the sick and healthy.

In an appendix clinical reports of several cases are given. We append a typical one together with the reproduction of a photograph of the patient.

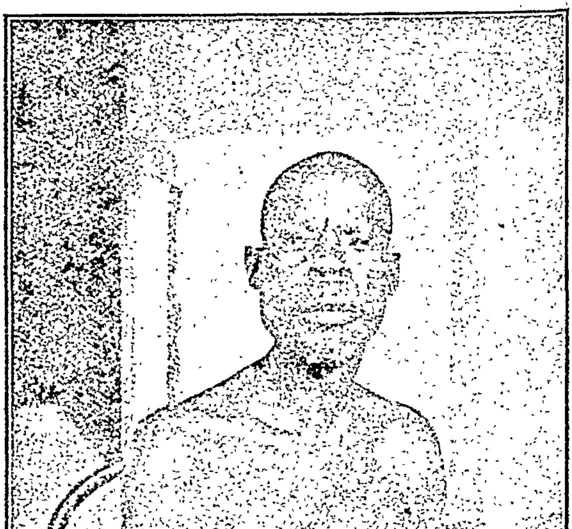
CASE 21.—Kidorme (male). Age 20. District, Bussi. Occupation, Leadworker. Food, Fish, Sweet Potatoes, and Bananas.

March 24th, 1903. Admitted to hospital. Patient states that his illness began with cough and pain in his chest and that he has been ill about three months.

April 7th. He is weak on his legs, being only able to totter along. There is tremor of the fingers. His pupils are equal and normal. His speech is indistinct, weak, and monotonous.

April 22nd. *General condition.*—He is well nourished. His gait is weak and uncertain; he walks carefully with bent legs. He is intelligent and the expression of his face is fairly bright. There is no œdema anywhere. The mucous membranes are normal. No trophic changes.

FIG: 3.



A case of sleeping sickness.

enerally enlarged, about the size of beans in
e does not complain of any pain. *Nervous*
memory are good. He lies about all day but
does not sleep much during the day. Speech rather weak and indistinct. Eyes normal. Tongue jerky. Tremor of lips and hands and generally of body. His sensibility to touch is normal, as also is his muscle sense. Knee-jerks are present. Ankle clonus absent. *Alimentary system.*—His appetite is good; tongue moist, furred; and gums are healthy. The liver and spleen are not enlarged. Bowels regular with use of medicine. *Circulatory system.*—Apex beat is imperceptible. Heart sounds weak. No bruit. Pulse 120; small, tension low, com-
ory system.—Nothing abnormal.

The following table shows the presence or absence of trypanosomes in the cerebro-spinal fluid and blood :—

Date.	Parasites in blood.			Parasites in cerebro-spinal fluid.	
	Filaria.	Malaria.	Trypanosoma.	Filaria.	Trypanosoma.
1903.					
March 28th					+
April 18th	+		+		
„ 22nd		–			

Post-mortem.—14 hours after death. Th[illegible] nourished young man of about 20 year[illegible] marked. A slight superficial bed sor[illegible] [illegible] it and the brain. [illegible] ickness appearance. The vessels are injected, the convolutions are flattened, and the sulci are filled with an excess of sub arachnoid fluid, giving them a ground-glass appearance. On section the white matter shows congested points, the lateral ventricles contain about six cubic centimetres of cerebro-spinal fluid, otherwise the brain appears healthy to the naked eye. *Thorax.*—No fluid in either pleural or pericardial cavities. *Heart.*—Weighs eight ounces. There is a slight excess of fat in the epicardium. There are no petechiæ and nothing abnormal, except a slight deposit of atheroma at the beginning of the aorta. *Lungs.*—Left weighs one pound There is some congestion of the lower lobe, otherwise the organ appears healthy. Right weighs one pound and is in the same condition as the left *Liver.*—Weighs three pounds two ounces. The surface is somewhat rough to the touch, like morocco leather. On section the lobules stand out rather prominently, due probably to dilated peripheral capillaries. There are dark ramifying [illegible] section the tissue appears healthy. *Alimentary system.*—The mesenteric glands are enlarged to the size of beans. The intestines appear healthy.

Remarks.—An ordinary uncomplicated case of sleeping sickness The accompanying photograph (see Fig. 3 was taken of Kidormo a month before he died, and it must be admitted his appearance is that of an ordinary healthy native.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Dec. 12th, Mr. JOHN TWEEDY, the President, being in the chair.

The Diploma of Fellowship was issued to 19 candidates.

On the recommendation of the court of examiners it was resolved :—

That the s[illegible] West Londo[illegible] be included [illegible] Members of [illegible] practice, aft[illegible] under the co[illegible] the Diploma of Fellow.

The Council also received a report from the court of examiners on the report of the visitor and inspector of the General Medical Council on the final examination of the Conjoint Examining Board in England. The report of the court dealt with all the complaints made by the visitor and inspector and showed that the suggestions made were all undesirable or impossible except that relating to the system of marking, as to which the court made some recommendations. The Council approved and adopted the report and directed that a copy of it should be forwarded to the General Medical Council as its reply to the criticisms of the visitor and inspector of the General Medical Council in regard to the final examination in surgery of the Conjoint Examining Board in England.

Diplomas were directed to be issued to the 72 successful candidates for the Licence in Dental Surgery. A report from the board of examiners in dental surgery was received. It referred to the undesirability of men who had passed in the dental section only of the examination for the Licence in dental surgery and who [illegible] the general section, being able to describe [illegible] the dental subjects, and it sugge[illegible] compulsory for candidates to p[illegible] before examination in the dental section. The Council adopted the report and directed that the necessary alterations should be made in the regulations.

The PRESIDENT reported that, in accordance with the unanimous recommendation of the board of examiners in dental surgery, he had authorised the board to hold in February, 1904, an additional examination in general anatomy and physiology, and general pathology and surgery (Part I. of the Second Professional Examination for the Licence in Dental Surgery).

These proceedings of the President were approved and confirmed.

A report was received from the committee on the annual report of the Council. It described the meeting, as already reported in THE LANCET of Nov. 28th, p 1521, and recommended the action to be taken on the resolutions passed at that meeting.

In reference to resolution No. 1 the Council resolved :—

That in the opinion of the Council it is not expedient to reopen the question of the representation of Members of the College on the Council.

In reference to the second resolution the Council resolved :—

[illegible] not expedient to reopen [illegible] of the College on the [illegible] e served by receiving a [illegible]

The Council also resolved that a copy of these resolutions of the Council should be sent to the respective movers and seconders of the two resolutions.

With reference to the motion proposed by Dr. W. G. Dickinson and afterwards withdrawn, the Council resolved that the minutes of the Council should be posted in the library and common room as well as in the hall of the College and that Section I. of the regulations of the Council should be amended accordingly.

It was resolved that the clause No. 4 of Section 23 of the rules relating to meetings of Fellows—viz , "A meeting shall be held in each year on the first Thursday in July after the annual election of the Council on that day"—should be suspended during the year 1904.

It was resolved that there shall be a Fellows' subscription dinner at the College on the day of the Council election and it was referred to a committee to make the necessary arrangements for July, 1904.

The PRESIDENT reported the delivery of the Bradshaw lecture by Mr. Henry Morris, the subject of the lecture being Cancer and its Origin. The best thanks of the Council were given to Mr. Morris for his lecture and he was requested to publish it.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at its late session. The best thanks of the Council were given to Mr Bryant for his services as the representative of the College.

A letter was read from the Clerk of the Privy Council forwarding a further memorandum from the Director-General of the Army Medical Service, with more detailed statistics as to the percentage of recruits rejected and the causes of rejection and asking that these documents should be taken into consideration. It was resolved to refer the documents to the committee appointed by the Council in July last and to request that committee to send a reply to the physical [illegible] committee [illegible] hase [illegible] S, for presenting to the College an engraving of Mr. Benjamin Harrison, formerly the treasurer of Guy's Hospital, and also for a case of instruments for ligaturing the subclavian artery, invented by Dr. Mott of New York and presented by Dr. Mott to Mr. Bransby Cooper.

On the motion of Mr. A. W. MAYO ROBSON and Mr. R. CLEMENT LUCAS it was resolved to appoint a committee to consider the relation of the medical profession to the coroner's court.

HOSPITAL FOR MID-CHESHIRE.—The Mid-Cheshire Joint Isolation Hospital authority, the first to be constituted in Cheshire, adopted plans on Dec. 4th for submission to the county council and the Local Government Board of a joint hospital for Northwich, Winsford, and Middlewich urban and Northwich rural districts. Estimates were presented showing that the cost, including the site, but exclusive of furnishing, &c , would be £13,537. The county council will bear one-third of the cost and will obtain borrowing powers from the Local Government Board. A small-pox hospital will have to be provided in addition on a separate site.

THE LANCET.

LONDON: SATURDAY, DECEMBER 19, 1903.

The Registration of Births and Deaths.

WE have received from the honorary secretary of the Leicester Medical Union a copy of a document entitled "Suggestions for an Act of Parliament to Extend and Amend the Law Regulating the Registration of Births and Deaths," and we congratulate the members of the Union upon having turned their attention to one of the most pressing of the medico-political questions of the day. All enactments governing domestic administration must from time to time be adapted to the ever-growing complications of national life; and the registration of births and deaths has remained unaltered since the consolidation of the Acts relating to the subject by the 37th and 38th of Victoria. In the course of the period which has since elapsed much knowledge has been gained with regard to the statistical value of correct registration, as well as with regard to the misleading character of the inferences likely to be deduced from careless and inaccurate returns, and, at the same time, our knowledge of the facilities for crime afforded by the present law has been materially increased. According to documents issued by the Registrar-General the uncertified deaths which were not made the subjects of judicial inquiry have amounted during the last ten years to something ranging from 1½ to 2 per cent. of the entire mortality of the kingdom; and not the least striking feature of the case is that this proportion differs widely in different parts of the country. During the last quarter, for example, there were no uncertified deaths in Rutlandshire, and the proportion was less than 1 per cent. in London, Surrey, Middlesex, Wiltshire, Somersetshire, Gloucestershire, Cheshire, the East Riding of Yorkshire, and Monmouthshire; but it reached 3·0 per cent. in Kent, 3·2 in Cumberland, 3·3 in North Wales, 3·4 in Bedfordshire, 3·5 in Derbyshire, 4·4 in Herefordshire, and 6·1 in Westmorland. The contrasts presented by urban districts were not less remarkable, for while the mean proportion in 76 great towns was 1 per cent., and while there were no uncertified deaths in Croydon, Willesden, Hornsey, Tottenham, East and West Ham, Southampton, Great Yarmouth, Derby, Stockport, York, Newport (Mon.), or Merthyr Tydfil, the proportion per cent. rose to 3·1 in Smethwick, in Bootle, and in Barrow-in-Furness, to 3·2 in Gateshead, 3·5 in Rochdale, 3·7 in Warrington, 3·8 in Rotherham, 4·2 in South Shields, and 4·6 in St. Helens. Neither the county nor the city of Leicester receives special mention, a circumstance from which we may infer that the action of the members of the Medical Union has been guided by considerations of a general character rather than by any special experience gained in the localities in which they live.

Of the 1781 deaths which in the third quarter of 1903 were registered without certification the returns furnish us with no particulars. We are not told in what proportion they were those of young children or of aged people, the two classes in which death is most likely to be brought about, directly or indirectly, by cupidity or by neglect. It is probable that some causes have been assigned for this mortality, but no one can tell in what proportion such causes may have been those actually in operation. During the same quarter the causes of death were certified in 8296 cases by coroners after inquisition, and it is manifest that an increase of this number by something more than one-fourth, while entailing but small expense, would materially have increased the public safety. We do not need SHAKESPEARE to tell us the frequent dependence of ill deeds upon opportunity; and a locality in which it becomes known that registration can be easily effected, and that the absence of a certificate will be excused or disregarded, quite naturally becomes a happy hunting ground for the agents of those perverted forms of the insurance office or of the burial club which have been responsible for so many instances of unexplained decease. A minor but still an important consideration arises from the extent to which the want of certification introduces an element of inaccuracy into the returns of the causes of death and diminishes their usefulness as the basis of conclusions upon questions of public health. At St. Helens, for example, where there is a population of rather more than 85,000 and an average mortality of 475 deaths per quarter, there would be an average of 78 uncertified deaths in the year; and it is easy to conjecture the extent of error which might thus be introduced into any calculations concerning, say, the mortality attendant upon some particular local epidemic or cause of disease. The existing state of the law, therefore, strikes at the root of the accuracy of registration as well as at that of its completeness, and in regard of both it falls much below the scientific requirements of the present day. In addition to all this, it casts a wholly unjustifiable burden upon medical practitioners who are required to furnish certificates of the cause of death in all cases which they have attended and in which there is no suspicion of foul play, without any provision for their remuneration, either by the relatives of the deceased or by the State.

The evils and abuses thus referred to have long been flagrant and have more than once been made the subject of official representation to the Privy Council by the General Medical Council, but so far wholly without effect. It may be added that the office of Registrar-General, which has for its main object to chronicle the causes of death and to derive from them whatever lessons they are calculated to teach, instead of being regarded as one which is in its very nature medical, has hitherto been conferred upon non-medical gentlemen. The Leicester Union does not touch this aspect of the case but is content to suggest that no burial shall take place without a medical certificate, that every birth shall be certified to the registrar either by a medical practitioner or by a registered midwife, and that no *stillborn* child shall be buried without a medical certificate, provisions being introduced to meet the accidental absence of a person entitled to certify. So far the "suggestions" ought to command universal assent; but there is also one which would require a practitioner who had been in attendance during an illness to see the body of his deceased patient before certifying, and within 24 hours of death, or to depute some other practitioner to do this on his behalf. We have heard objections to this proposal on the part of medical men who have alleged that the discharge of the duty might sometimes be troublesome or inconvenient, but we think, especially as the suggestions provide for payment, that any such trouble should be faced. It would hardly be consistent with professional dignity and rectitude to certify even the fact of death, when this is done as a public duty, merely on a basis of hearsay information, and there could be no overwhelming inconvenience in paying another visit where presumably several have been paid before. The medical profession, with everything to gain by the better enforcement of registration, should be the last to object to an enactment which would invest it with due and proper formality. As regards the important question of remuneration, the suggestions are only defective in so far as they neglect to say by whom it should be provided. They recommend a payment of 5*s.* for a medical certificate of the *cause* of death and a payment of 1*s.* for a certificate of the *fact* of birth, thus making a proper distinction between the value of professional and of what may be called common knowledge. The proposed service is for the good of the State and it is clearly by the State that the expense of providing it should be incurred. The proposed payments would yield something between £160,000 and £200,000 a year to the profession; and whenever there is any prospect of the question being submitted to Parliament the medical men in every constituency should impress upon their representatives the absolute dishonesty of the demand hitherto made upon their time and skill, and the strength of the arguments in favour of their being paid as public officials for the discharge of important public duties.

The Results of Operative Treatment of Perforating Gastric and Duodenal Ulcer.

FOR more than ten years it has been the routine treatment to deal with perforated ulcers of the stomach by laparotomy and sufficient time has now elapsed to enable us to form a clear idea of the operation and its results. It is true that the records of many cases have appeared in THE LANCET and other medical journals, both in this country and abroad, and these have been collected from time to time and analysed, but the statistics founded on the results of these published cases have but little value, for successful cases are far more likely to appear in a medical periodical or to form the basis of a paper read at a society than are those in which the issue has been unfortunate. There are several reasons for this. In the first place every surgeon feels a perfectly justifiable pride in the recovery of a case which he has submitted to operation and therefore he is more likely to put it on record; secondly, an unfavourable result may be, and often is, due to some peculiarity in the case itself or to the time at which it comes under treatment, and therefore it may in itself be less instructive; and in the third place, especially when an operation is new, the surgeon is liable to attribute a fatal result in some degree to a lack of acquaintance with the technique of the operation. As a result of these natural tendencies single cases, whether recorded in the journals or in the transactions of the societies, should be excluded from statistics which claim to be of real value, because it will be found that single cases are far more likely to be successful than unsuccessful. It is then on series of cases that we must rely if we wish to obtain a trustworthy statistical idea of the mortality following any operative procedure.

A complete list of the cases under any one surgeon will give a far better view of the risk of an operation, but of greater value still is a series of cases occurring in a hospital, for thus not only are we likely to obtain a greater number of cases but, inasmuch as it will include the practice of several surgeons, the personal factor will tend to be eliminated. In this issue of THE LANCET will be found a series of cases of operation for perforation of gastric and duodenal ulcers treated at St. George's Hospital. The cases number 50 and have been collected by Mr. T. CRISP ENGLISH who has also analysed the facts connected with them and thus has conferred a distinct service on surgery. Of course from this series have been excluded those cases in which moribund patients with perforated ulcers were admitted and in which no operation was performed. The first question which Mr. ENGLISH has attempted to solve by his series of cases is, What signs are there of impending perforation—and he has shown that in a certain proportion of the cases there were a progressive increase of pain and vomiting for a few hours or even for two or three days preceding perforation. This increase of severity of symptoms might prove of value in enabling surgical aid to be at hand should perforation result. In three cases perforation occurred in patients already in the hospital and curiously all three patients died; in one of the cases death was due to a duodenal ulcer opening up the gastro-duodenal artery. The signs of perforation are generally sufficiently clear; the sudden intense and abdominal pain is the most important of these while vomiting was present in over 75 per cent. of the cases. During the stage of reaction the patient may show few signs and in one case a man walked into the hospital merely complaining of "stomach-ache" although he had general peritonitis from a perforated duodenal ulcer. Mr. ENGLISH considers that not only morphine but also stimulants such as alcohol or strychnine may produce such temporary improvement as to mask the symptoms and to lead to the postponement of an urgent operation. We have on several occasions pointed out that the presence or absence of liver dulness is of no value in the diagnosis of perforation and Mr. ENGLISH's statistics support this view, for in 11 out of 43 cases the liver dulness was normal in spite of perforation having occurred.

The percentage of recoveries after laparotomy for perforation of gastric and duodenal ulcers is certainly encouraging. In the case of gastric ulcers the percentage of recoveries was 52 and in the case of duodenal ulcers it was 25. The proportion of recoveries is increasing, for of the first ten cases only three patients recovered, while of the seven patients admitted during 1903 six have recovered. We hope that when the number of cases at St. George's Hospital reaches 100 we may have the statistics brought up to date, for the larger the number of cases in a series the more trustworthy are the conclusions to be drawn therefrom.

◆

Herbert Spencer.

THE hand of death has removed from the ranks of the living another of the triumvirate who conceived the theory of evolution, laid the foundations, and completed the mighty edifice. We do not attempt to appraise the size or the value of the part which each artificer contributed to the completion of the whole. It must be remembered, however, that HERBERT SPENCER'S achievement was unique in the annals of literature; with a limited scientific equipment, with no classical training, and with, at first, no conspicuous literary gifts he imposed upon himself, the task of systematising all knowledge and of symbolising in concrete ideas the processes whereby organic and inorganic nature had arrived at the stages of development at which he found them. He assumed at the commencement of his task that there were certain immutable laws which were responsible for all conditions of change, and as a sequence he laid it down that in all the phenomena of the material world there was a gradual passage of matter "from an incoherent homogeneity to a definite coherent heterogeneity, during which the retained motion undergoes a parallel transformation." Applying and extending this general formula to the interpretation of particular phenomena he sketched in his "First Principles" the outline of a philosophy which covered the entire ground of biology, psychology, sociology, and ethics. At the time that he moulded the skeleton of the system which he ultimately clothed with adequate tissues his knowledge of biology, psychology, sociology, and ethics was admittedly small. He was, as he described himself, "merely a synthetic philosopher," a systematiser of the work of others. His knowledge of the completed anatomy of his skeleton, with its nerves, its muscles, and its integuments, was still to be acquired, and was acquired as he proceeded with his task and then published for the benefit of the world in the volumes which unfolded the details of his many-faceted philosophy. The real greatness of the man is not least revealed in the fact that never, or practically never, was he compelled by force of evidence to abandon any of the original propositions which he laid down in his "First Principles," or, with maturer experience and knowledge of the subject, to modify any of the important views which he therein enunciated. Guided entirely by first principles and laws which were universally applicable he seldom fell into gross error, and by reason of the exactness of his methods few could criticise or find fault with his less important observations. The principles which HERBERT SPENCER enunciated are to-day accepted all the world over as the basis of an exact philosophical reasoning and his conceptions have influenced the directions of progress of almost every science. Biology has by no means been the least to profit by his work. Medicine has as yet reaped benefits which were hardly comparable with those which he has conferred on kindred branches of science; indeed, the full significance of his definitions of life and death and disease are by no means to-day as fully valued by those who attempt to unravel the problems of pathology as they undoubtedly deserve to be. The conception of disease as a "disturbance of organic equilibrium," a perverted manifestation of energy, and an uneconomical redistributing force, is one which has only found expression in some few of our medical writers who have come under the influence of his genius. But pathological manifestations, like all other natural phenomena, are subject to immutable laws, and as medicine becomes more and more an exact science we may expect to see among its practitioners a wider appreciation of HERBERT SPENCER'S synthetic work.

HERBERT SPENCER was himself little interested in the problems of pathology, but such generalisations as he occasionally ventured to form had an illuminating influence on the conception of morbid processes. It has been a loss to medical progress that his philosophy extended so little in this direction. Up to the end of his illustrious career he fought with all the energy and the sincerity of which his profound mind was capable for the principle that acquired characteristics were, and must be, inherited. The truth or falseness of this postulate was, he contended, of the utmost importance to the progress of mankind, for according to the manner in which men regard this question so are determined their actions in politics, ethics, education, and sociology. In the appendix of the last edition of his "Principles of Biology," which was written only a few years before his death, and which therefore may be accepted as representing his final word on this subject, he expresses the depth of his feeling in the following words: "And now I must once more point out that a grave responsibility rests on biologists in respect of the general question (inheritance), since wrong answers lead, among other effects, to wrong beliefs about social affairs and to disastrous social actions. In me this conviction is increasingly strengthened. Though the 'Origin of Species' proved to me that the transmission of acquired characters cannot be the sole factor in organic evolution, yet I have never wavered in the belief that it is *a* factor and an all-important factor. And I have felt more and more that since all the higher sciences are dependent on the science of life and must have their conclusions vitiated if a fundamental datum given to them by the teachers of this science is erroneous, it behoves these teachers not to let an erroneous datum pass current; they are called on to settle this vexed question one way or other." The truth or the reverse of his views on the inheritable qualities of acquired characteristics is of universal importance, but more especially so in medical science; and although his proposition is by no means opposed to the accumulated evidence of clinical experience, nevertheless deductions from morphology, laboratory experiments, and microscopic investigation at least lay it open to serious doubts. As we have already said, HERBERT SPENCER'S views have seldom proved wrong. His purview of organic evolution was so far-reaching in extent that we must hesitate many times before we reject on grounds of detail a proposition in which he firmly believed and which was material to the stability of his great argument.

"Every change," wrote HERBERT SPENCER in his "Principles of Biology," "is towards equilibrium, and that change can never cease until equilibrium is reached." And again he postulated: "Evolution is an integration of matter and concomitant dissipation of motion." In his own powers of mental cerebration he provided one of those great climaxes of intellectual evolution which at times anticipate, perhaps by generations, the progress of knowledge. The integrated forces from which proceeded this intellectual outflow have now found their equilibrium and that life which was devoted to the fathoming of the knowable has passed to the regions of the unknowable. The influence of his intellect will persist, permeating men's minds and substantiating his conceptions in psychology.

◆

The University of London and Medical Education.

WE publish in another column a thoroughly well-justified appeal made by the University of London for funds to support an adequate system of medical education in the metropolis. The appeal takes the form of a letter signed by the Earl of ROSEBERY, the Chancellor of the University; Dr. P. H. PYE SMITH, the Vice-Chancellor; Sir ARTHUR RUCKER, the Principal; Mr. H. T. BUTLIN, the Dean; and Dr. J. KINGSTON FOWLER, a member of the Senate; and in this document all the arguments for the foundation of a central institute for the preliminary scientific education of the medical student are succinctly set forth. A Royal Commission has recommended that the teaching of such subjects as physics, chemistry, biology, anatomy, physiology, and pharmacology should be concentrated into one or two central institutions. The recommendation was adopted by the Statutory Commission responsible for the statutes of the reconstituted University and has since been endorsed by the faculty of medicine, which has urged upon the Senate the advisability of carrying out a project so importantly brought to its notice. Lord ROSEBERY and his co-signatories have, therefore, behind them an enormous weight of deliberate and authoritative opinion when they appeal to the public for funds to establish in connexion with the University of London a central school for the teaching of subjects ancillary to the acquisition of medical science or preliminary to the practice of medical doctrines. We trust that the appeal will be generously responded to.

The affairs of the University of London have lately been much in evidence. The address recently delivered by Sir ARTHUR RUCKER on the work and aims of the University of London marked a distinct forward step in the organisation of education in the metropolis. It is not a matter for surprise that some considerable time should have elapsed before the Senate of the reconstituted University was able to announce to what small portions of its mighty task united effort would first be directed. The irresponsible critic has frequently in the last three years grumbled at the apparent absence of immediate results from the work of the Statutory Commission, and even in the three important schemes which the Principal of the University commends to the attention of a generous public, it is not impossible to find features which fail to command universal approval. Fortunately, while recognising the impossibility of pleasing all parties the authorities move forward, doubtless carefully considering the criticisms, and taking every precaution to avoid the pitfalls pointed out to them. Mr. T. BAILEY SAUNDERS, whose work as secretary of the Statutory Commission gives his opinion on university matters weight, has lately indicated the difficulties that will have to be overcome, if the scheme, which is usually called Lord ROSEBERY'S Charlottenburg scheme, is to achieve the good results hoped for by its promoters. Sir ARTHUR RUCKER'S reply to these criticisms makes it clear that most of Mr. SAUNDERS'S objections have already been noted by the authorities. It remains to be seen with what success the powerful and representative committee now considering the details of Lord ROSEBERY'S proposal will be able to devise a scheme which, while filling vacant educational spaces, will not unduly interfere with existing institutions. Difficult as is the problem it certainly should not prove insoluble. Almost immediately after it had been officially announced that an additional amount of £100,000 would enable the incorporation of University College with the University of London to be carried into effect the satisfactory news came to hand that the College had received an anonymous donation of one-half the needed sum. We offer our hearty congratulations to the authorities of University College upon this latest indication of the public appreciation of the good work which they have done in the past under difficult conditions.

The last of the three aims of the University which the Principal linked together as requiring and deserving the immediate support of the public purse is that in which the medical profession is most interested—namely, the proposal to build and to endow an institute of medical sciences in the near neighbourhood of the University. The Principal stated that this scheme was well in hand and that the proposal was receiving the warm support of the Senate, and now the letter, which we publish to-day in our columns, shows that it is intended to make an immediate attempt towards its realisation. We understand that promises of pecuniary help towards this object are somewhat difficult to obtain. London has not been accustomed to find money to promote medical education, and it will require much eloquence on the part of those who recognise the value of concentration to persuade the wealthy public to subscribe the considerable sum required to build and to endow the institute. Nevertheless, we are confident that the example that has been set in provincial universities and colleges will shortly be followed by wealthy citizens of London. Sir TREVOR LAWRENCE, in defending the original determination of the governors of St. Bartholomew's Hospital to rebuild their charity on what is now allowed to be an inadequate site, alluded to the subject in a suggestive way. He pointed out that the taking over by the University of the teaching of certain subjects of medical education now taught at the hospitals will provide, in hospitals having medical schools attached, an automatic extension of their sites. This is no doubt true and is not the least of the many advantages of concentration. We, however, think that the space freed in hospitals by the relegation of some of the earlier courses of the students to a central institute would almost immediately be made use of for those improvements in the teaching of pathology, bacteriology, and other clinical subjects which the progress of medical education will inevitably demand. However this may be, it is of interest to note that the lay authorities of the hospitals in London are beginning to recognise that, by the help of the University of London in relieving them of some of the burden of medical education, the difficult problem may possibly be solved of providing for the ever-increasing demands of scientific medicine upon the defined but costly sites which most of the hospitals occupy.

Annotations.

"Ne quid nimis."

THE CASE OF DR. LACHLAN GRANT.

IN THE LANCET of Dec. 5th we drew attention to the then existing position of the dispute between the quarriers of Ballachulish and the directors of the quarry company. We said that if the men held out the shareholders would insist upon the matter being settled in the men's way. We now learn that on Dec. 9th two members of the quarriers' committee, together with Dr. Grant, went to Edinburgh at the request of their legal advisers. On arrival they were told that the company's secretary had approached the quarriers' lawyers with a view to a settlement. Eventually it was agreed between the directors on the one hand and the quarriers' representatives and Dr. Grant on the other that Dr. Grant's appeal to the House of Lords should be withdrawn, that the quarriers' appeal to the Inner Division of the Court of Session should be withdrawn, and that the company would suspend its interdict against Dr. Grant practising in Ballachulish. Dr. Grant and the directors have signed an agreement, the quarriers consider that the labour terms already agreed to are satisfactory, and now all that remains is that the quarriers themselves should agree to the terms accepted by their representatives. This we should think there is no doubt of their doing. So the dispute may be said to be at an end and Dr. Grant and the quarriers have won all along the line. From a strict legal point of view the directors had a right to terminate their agreement with Dr. Grant. But it was foolish of them to do so, and they found that they were unable to get another medical man to take over Dr. Grant's work permanently. The quarriers have acted towards Dr. Grant magnificently all through the trying times which have now passed. Their club is, indeed, one worth working for and Dr. Grant may well be proud of having gained the confidence and esteem of such a worthy body of men.

THE METROPOLITAN HOSPITAL SUNDAY FUND AND THE KING'S HOSPITAL FUND FOR LONDON.

WE publish this week an abstract of the report of the King's Hospital Fund for London for the past year which sufficiently shows the magnificent work that has been accomplished. A sum of £100,000 will be distributed among the hospitals, the awards having been made as usual with generosity as well as with scrupulous discretion. We publish also a report of the annual general meeting of the supporters of the Metropolitan Hospital Sunday Fund, which Fund has been instrumental in collecting and distributing a sum of £64,975. Magnificent as these sums are the wants of the hospitals are so urgent that they are absorbed without making any apparent difference to the prevalent financial depression of our noblest London charities. Ask, however, the treasurers of the different institutions what the receipt of an annual donation from these funds means and it will be found that the grants are welcomed with the greatest gratitude. They are doubly valuable as, first, the receipt of them is a testimonial to good management, and secondly, the augmentation of funds comes with approximate regularity and in some proportion to the urgency of the needs. If the public knew what a relief the certainty of being able to meet particular claims with particular receipts brings to those who are responsible for the pecuniary management of the London hospitals, surely they would help these two splendid funds to do a still greater work.

BUTTER STANDARDS.

IN the words of the fourth section of the Sale of Food and Drugs Act, 1898, "the Board of Agriculture may after such inquiry as they deem necessary make regulations for determining what deficiency in any of the normal constituents of genuine milk, cream, butter, or cheese, or what addition of extraneous matter or proportion of water in any sample of milk, cream, butter, or cheese, shall for the purposes of the Sale of Food and Drugs Act raise a presumption, until the contrary is proved, that the milk, cream, butter, or cheese is not genuine or is injurious to health and an analyst shall have regard to such regulations in certifying the result of an analysis under those Acts." For a long time there has been considerable difficulty amongst analysts in drawing a uniform inference from the results of their analyses in regard to butter. The difficulty has been increased by the fact that butter fat varies in composition in accordance with the different conditions (such as climate and feeding) under which it is produced in different places. The difficulty became acute when it was shown that certain imported butters gave abnormal results, though there was no doubt about their genuine character. Analysts have commonly based their inference as to the genuineness or not of a butter upon the amount of soluble or volatile acids that it contains and a fairly constant number was used as a semi-official limit. It was soon found, however, that though this limit could be fairly applied to home-produced butters it could not be so applied to certain butters imported from abroad. In other words, certain butters showed a deficiency in volatile acids although the samples were undoubtedly genuine. The subject therefore was one requiring serious attention and a departmental committee was appointed by the Board of Agriculture to deal with it, and the recommendations just published in its final report appear to us to be, on the whole, well founded. The committee was appointed in July, 1901, and in an interim report issued in January, 1902, it unanimously recommended the adoption of a limit of 16 per cent. for the proportion of water in butter. We believe that this limit has worked well in practice and has not imposed any hardship upon the trade, but, as we have pointed out before, it is a pity that the operation of this limit can be avoided provided that a sufficient disclosure of the fact be made to the purchaser. This system of disclosure seems to us to reduce the Sale of Food and Drugs Acts in many cases (notably in spirits and the milk sold in restaurants) to a dead letter. However, in its final report the committee deals with the question of what regulations, if any, should be framed for the purpose of directing an analyst appointed under the Sale of Food and Drugs Acts when to raise a presumption that a sample of butter has been mixed with foreign fat. Without going into such details of the report, as, for example, the chemical nature of butter, the composition of butter fat and of butter substitutes, and analytical methods, it may be stated that the committee has decided to recommend a limit based on a deficiency in the normal constituents of butter. The opinion of the committee is that if the amount of the volatile acids in any sample of butter as determined by the Reichert-Wollny method should fall below the number 24 a presumption should be raised that the butter is not genuine. In arriving at this decision the committee had before it the evidence of analytical experts and the tabulated results of some thousands of determinations more particularly of the volatile acids contained in butters of very variable origin. As a result it was shown that more than nine-tenths of the samples have a Reichert-Wollny number comprised between the limits of 24 and 33, and that by far the greater amount of these are comprised between the limits of 26 and 31. Many of the exceptional instances were the produce of single cows or of very small herds. The opinion is expressed that as the butter which comes within the purview of the Sale of Food and Drugs Acts is the product of large herds or the mixed products of different dairies, abnormalities due to idiosyncrasy or to exceptional causes tend to disappear. The committee assumes that the proposed limit will not act prejudicially upon any appreciable quantity of butter made in the United Kingdom or upon colonial, American, Argentine, Danish, Swedish, French, or Italian butter, but it may occasionally affect to a small extent, and then only for a short time during the year, the butter from Norway, Siberia, and Holland. An important step is suggested in regard to margarine, and that is that the use of 10 per cent. of sesame oil in the manufacture of margarine should be made compulsory. As it is remarked, fraud might be considerably checked if margarine were required to contain, as is the case in Germany, Austria, and Belgium, and as is contemplated in France, some "tell-tale" or indicative substance sufficiently sensitive to allow even small quantities of the margarine to be detected. The report is signed by ten of the members of the committee, three of whom, however, make certain reservations. Mr. C. J. Dunn and Mr. J. Gilchrist refer to the limit of 24 and suggest that the figure 23 would be safer, while Mr. P. G. Craigie is of opinion that it is premature yet to fix a limit in view of the cases of variations brought to the notice of the committee. Finally, Mr. Patrick Hickey found himself unable to sign the report because his views were at variance with the conclusions of the majority. He has, therefore, added a separate report in which he gives his conclusions for thinking that the evidence presented to the committee does not afford solid grounds for the fixing of any limit based upon the proportions of volatile acids.

THE VIVISECTION QUESTION IN THE PAST.

QUESTIONINGS as to the justifiability of vivisection and expositions of the results obtained by means of experiments upon live animals are by no means new. So long ago as 1709 Christian Sigismund Wolff published at Leipsic a disputation as to the morality of anatomy when occupied with living animals ("De moralitate anatomes circa animalia viva occupatæ") and in 1722 Apinus contributed to the literature of the law of nature a dissertation on the same theme. The book was published at Altorf and its quaint title runs, "An licet brutorum corpora mutilare et speciatim ob es recht sey, dass man den Hunden die Ohren abschneide, variis observationibus aucta et a nonnullorum objectionibus vindicata." After the time of Apinus' library catalogues omit any mention of this vivisection literature until in 1824 appears a judicious dissertation by Gerdy of the University of Paris in which the claims of vivisection are weighed *pro* and *con*. Gerdy's book is followed a year later by a Copenhagen *prize essay from the pen of Dr. P. W. Lund*. The book is a detailed exposition of the benefits and discoveries *due to vivisection*. *It* deals with discoveries concerning reproduction, digestion, and the functions of the *intestines generally*, all of which have been arrived at by means of the experiments of such men as Blundell, Haighton, Magendie, and Wilson Philip, to mention English-speaking physiologists alone. Such a book as Dr. Lund's, carefully compiled and issued by authority, is, despite its antiquity, a sufficient answer to the silly modern query: "What has vivisection discovered?" The older writers were never really doubtful of the use of vivisection both to science and to humanity. Mr. Pepys, for instance, after recording "a pretty experiment of the blood of one dog let out into the body of another," writes optimistically of the possibilities of the experimental method in the future. "Mr. Hooke …… tells me," says he, "the dog (into the body of which blood had been transfused) is very well and doubts not its being found of great use to men, and so do Dr. Whistler, who dined with us at the tavern."

ST. BARTHOLOMEW'S HOSPITAL.

WE have received the following communication from the governors of St. Bartholomew's Hospital:—

> [illegible] lieve that they have the unani- [illegible] the action they have decided to [illegible]

We have also received this letter from the medical council of the hospital:—

To the Editors of THE LANCET.

St. Bartholomew's Hospital, Dec. 10th, 1903.

SIRS,—We, the members of the medical and surgical staff of St. Bartholomew's Hospital, wish it to be known that we support most cordially the [illegible] essential is the [illegible]

We beg to [illegible] ew buildings, and acquisition of [illegible] on the extended the ultimate [illegible] area.

I[illegible] we are in hearty agreement with the [illegible] ire more land and to erect first and [illegible] ut-patient block, on account of the [illegible] which will be included in this building.

[illegible] rs will necessitate the [illegible] id other new buildings [illegible] of the most complete [illegible] rily depend the future [illegible]

[illegible]

T. HOLMES SPICER.
A. E. CUMBERBATCH.

We heartily congratulate the governors of St. Bartholomew's Hospital upon the decision to which they have come and all the more so because we applied the major portion of the stimulus which has brought about so prompt a response. We may remind the governors of the hospital that on July 2nd, 1900, Sir Sydney Waterlow remarked at a special court of governors: "Personally I do not think that the purchase of the whole site (of Christ's Hospital) would be a very speculative undertaking."[1] Only late, however, have the governors made up their minds and already we hear of formidable rivals who are anxious to obtain the remainder of the site of Christ's Hospital. The most dangerous rival in the field is the Post Office, an organisation which without doubt is cramped for room. But the claims of St. Bartholomew's Hospital are paramount and we can but hope that an institution with such a noble history, the Patron of which is the King, the President of which is the Prince of Wales, and which is the one hospital within the City of London, will not be allowed to be outbidden in its desire for more land by any other organisation. Some five weeks hence the citizens of London will have all the details laid before them at the Mansion House meeting. If the governors make a bold and large appeal we repeat our opinion that such an appeal will not fall on deaf ears.

---

[1] THE LANCET, July 7th, 1900, p. 43.

SIR WALTER BESANT AS A LONDON CITIZEN.

AN interesting little ceremony was performed on Dec. 11th, when a memorial was placed in the crypt of St. Paul's Cathedral to Sir Walter Besant. Sir Walter Besant's literary work and position do not call for detailed comment in THE LANCET, but his deep interest in London had its distinct medical side. Lord Monkswell, the chairman of the London County Council, to whom the unveiling of the monument was entrusted, pointed out that the especial fitness of a memorial to Besant in St. Paul's Cathedral lay in the fact that his unrivalled knowledge of London went hand in hand with a deep and genuine sympathy for the poor of the great city. Such men as Besant, said Lord Monkswell truly, give enormous aid to municipal bodies in their attempts to brighten and to sweeten the lives of the needier classes under their jurisdiction. In all Besant's work dealing with the metropolis there is evident knowledge that the foul environment produces the defaulting citizen. What is this but to preach the doctrines of sanitation?

PARACENTESIS THORACIS IN TRAUMATIC PNEUMOTHORAX.

BY far the most frequent cause of pneumothorax is the bursting of a tuberculous vomica of the lung into the pleural cavity, but pneumothorax may be the result of injury and then the air may be admitted into the cavity of the pleura in one of three ways. In the first mode by a bullet or a cutting weapon an aperture is made through the chest wall and the parietal layer of the pleura and the external air enters directly; this is, perhaps, the most common variety. In the second form there is no external wound but the force applied breaks a rib and the sharp end of this tears both the parietal and the visceral layers of the pleura and the air from the torn lung escapes into the pleural cavity. The rarest of all the forms of traumatic pneumothorax results from a rupture of the lung substance without any wound of the parietes of the thorax or fracture of a rib. This occurs especially in children, in whom the pliancy of the ribs permits their bending so that the full force of the pressure comes on the lung. If, at the same time the glottis closes from the sudden shock, the lung is liable to be ruptured and pneumothorax to be produced. The form of violence that usually gives rise to this lesion is the passage of the wheel of a cart over the chest. In recent issues of THE LANCET we have recorded two instances in which a traumatic pneumothorax was produced and in each of them the injurious effect of the pressure exerted by the air in the pleural cavity was relieved by the withdrawal of some of the air. In one case, which was under the care of Mr. R. J. Godlee in University College Hospital, the air was removed by means of a trocar and cannula, a tube being attached to the end of the cannula and dipping into a bottle containing sterilised salt solution. The other case was in King's College Hospital, under the care of Mr. F. F. Burghard, and in this instance an aspirator was employed. In both cases much benefit resulted from the operation and the question arises should paracentesis be performed in any cases of pneumothorax? and the further question follows, should simple tapping be preferred or should aspiration be done? The value of paracentesis in the analogous condition of pleurisy with effusion has long been recognised, and therefore it is natural that the operation should have been performed in pneumothorax. From time to time there have been discussions as to the advisability of attempting to remove the air from the pleural cavity and many of the text-books deprecate any interference on the ground that there is a possible danger of renewing the fistulous opening. This objection, however, applies chiefly to pneumothorax which has resulted from the rupture of a tuberculous cavity; for in the traumatic variety it would not apply. If it be determined, then, to perform paracentesis thoracis, which method, tapping or aspiration, is to be preferred? The answer to the question will depend on the intrapleural pressure. Mere tapping will suffice to relieve the pressure should it be above that of the atmosphere. Although it has been denied that the intrapleural pressure can ever exceed that of the atmosphere, yet it is clear, from the observations of Dr. Samuel West, for instance, that in many cases of pneumothorax the pressure, especially during expiration, may exceed the pressure of the atmosphere by several inches of water. If, however, there be no excess of intrapleural pressure it is obvious that no air will escape through a simple cannula and in such cases, other conditions permitting, the aspirator may be usefully employed. The relief to the dyspnœa has been very great in many recorded cases and in some the operation has appeared to rescue the patient from imminent death.

ANTIDIPSO.

THERE have been many cruel and wicked frauds committed by the sellers of quack medicines but of all that have come to our notice we do not know one of a baser character than that which is perpetrated by the proprietor of antidipso. This remedy is "run" by a person named A. L. Pointing who is referred to in our contemporary *Truth* in its issue of Dec. 10th. Mr. Pointing, who resides at Century House, Regent-street, appears to be responsible for the Century Thermal Bath Cabinet, Limited, the Grecian School of Physical Culture, the Espanola Medicine Company for increasing the size of the female bust, and the Ward Chemical Company which is responsible for antidipso. Antidipso is said to be a drug which in cases of drunkenness "can be given in tea, coffee, or food, thus absolutely and secretly curing the patient in a short time without his knowledge." So we learn from an advertisement which occupies a whole page in the December number of the *Strand Magazine* in company with such advertisements as Dr. Rice's Rupture Cure, the Espanola Medicine Company, and that of the well-known quack Dr. James W. Kidd. About ten days ago we sent a representative to Century House who purchased antidipso powders for which he paid 10*s.* He was also given two samples of the same and we will do the Ward Chemical Company the justice to say that the powders in the box and the sample were similar in composition. Ten powders weighed 2·733 grammes, being an average of 4½ grains for each powder. Their composition was as follows: bromide of potassium, 21·78 per cent.; milk sugar, 78·22 per cent. There is therefore in every powder an average of rather less than one grain of bromide of potassium. The printed matter accompanying the powders stated that up to six powders may be given per day and that antidipso is both alterative and curative. It may be alterative, whatever that means, but to say that it is curative *is a lie.* The 10*s.* box contained 48 powders which at a moderate estimate would cost the vendors ½*d.* for bromide of potassium and nearly 1*d.* for the milk sugar. We do not, however, so much object to the price—if people are so silly as to buy quack remedies they must expect to pay for them—but the heartless swindle is scandalous. To raise false hopes in those whose lot it is to be tied to a drunkard is disgraceful and no punishment can be too bad for the person who profits by such deceit. There is not the excuse that even if the drug is useless *per se* it may act by suggestion, for great stress is laid on the fact that it can be administered to a patient without his knowledge. Six grains or less of bromide of potassium per diem would have no effect whatever in restraining the craving for alcohol or in relieving the physical evils arising from the ingestion of alcohol. The proprietors of our lay contemporaries in these circumstances might surely consider the advisability of refusing to insert the advertisements.

VACCINATION FEES IN RURAL DISTRICTS.

WE publish in another column a communication from a correspondent dealing with the very pressing question of the charges for vaccination in rural districts and without at this stage entering into all the controversial matters which centre around the subject we may say that in our opinion the communication referred to sets forth the case from the point of view of the public vaccinator clearly, forcibly, and reasonably. All who are familiar with the difficulties in carrying out the provisions of the present Vaccination Act and Regulations in rural districts will, we think, recognise that the illustrations furnished by our correspondent are fair average examples of what actually occurs in practice. The present outcry against the cost of vaccination is no doubt largely the result of what some would call a fortuitous concourse of circumstances. On the one hand, it is due to the neglect of vaccination and revaccination in the past and, on the other, to the actual or threatened presence of small-pox. We are dealing, therefore, not only with a charge in respect to arrears but also with a charge relative to insurance in which all the premiums are being paid at one time in consequence of the fear of disease or death. Similarly those who have any knowledge of the routine work of the public vaccinator in rural districts will agree with our correspondent in recognising that under the present system there is an enormous amount of unremunerative work performed, and if the guardians call in question this fact let them inspect some of the H Forms which their public vaccinators have, in accordance with instructions, returned to the vaccination officers. The guardians will find that in some instances not 50 per cent. of the cases on the list have been vaccinated by the public vaccinator and that in the column for "remarks" there abound entries such as "refused," "will be done by own medical man," "left," "postponed," "cannot find," and the like. An examination of these H Forms will satisfy the guardians or the departmental committee which is at present sitting that our correspondent is not exaggerating when he states that in a certain instance "the public vaccinator had travelled 1172 miles to vaccinate 745 cases for a remuneration of £45, being a fraction over 9*d.* a mile," and hence it is that in some cases the remuneration works out at 2*s.* or 1*s.* 10½*d.* per visit. The clerical work under the present Act is certainly very considerable, more especially if the instructions are rigidly adhered to, and the guardians, as well as the medical inspectors of the Local Government Board, are becoming very strict in regard to these matters. We think that all reasonably minded persons will agree with our correspondent that any reduction of fees for primary vaccination in rural districts would be eminently unfair. With regard to revaccination it cannot be contended that the fees are too high, but possibly a little saving might be effected where several persons are revaccinated in the same house. Here the maximum fee might be allowed for the first case only. Similarly, the guardians might, during the actual or threatened presence of small-pox, more frequently provide stations for revaccination. The Local Government Board would not, we imagine, in these circumstances withhold its consent. That these stations have not been provided in the past in greater degree is due largely to the indifference of the guardians themselves who take no interest whatever in performing the administrative duties in this respect which have devolved upon them but who content themselves with protesting when a somewhat startling table of fees is presented to them. Of course, stations of this nature are less used in rural than in urban districts owing to the long distances which have to be travelled, but in towns during an outbreak of small-pox stations opened in the evening hours would effect a very material saving in the total charge for revaccination and it appears to us that if any retrenchment is considered desirable it is in this direction that it might be effected. But, as we have already said, the magnitude of the whole question has become distorted by the vast accumulation of arrears and the presence of small-pox.

THE INVESTIGATION OF MALIGNANT DISEASE.

A JOINT paper by Professor J. B Farmer, Mr. J. E. S. Moore, and Mr. C. Walker was read at a meeting of the Royal Society on Dec. 10th. The paper contained the substance of some extensive investigations which have been undertaken by them into the structure of carcinomata and sarcomata. They found that the cells at the growing edge of a malignant growth exhibited peculiarities in their nuclear changes on division. When an ordinary healthy cell divides the nucleus undergoes the changes which are so well known, and the chromosomes which are formed are constant in number in each group of organisms. In the division, however, of reproductive cells the chromosomes are few in number, and this smaller number is never exceeded so long as the cell remains a reproductive cell. The authors of the paper have observed that the growing cells of malignant tumours exhibit on division the phenomena of reproductive cells, possessing only the smaller number of chromosomes. From this fact they deduce that the cause of multiplication must be physiological stimulus and cannot be parasitic in origin. The observations are of great interest.

IRISH FOLK-LORE.

Professor J. W. Byers recently delivered before the Belfast Natural History and Philosophical Society a lecture on the Stories, Proverbs, and Sayings of Ulster. Apart from their intrinsic interest, such *résumés* of popular humour render service to students of folk-lore, for with the spread of education many of the old-world beliefs in elves, and forms of "good people," and many charming local superstitions will naturally die out. The greater part of Professor Byers's lecture was occupied with what may be called the supernatural side of his subject, but he also dealt with many curious words and phrases used by Ulstermen. "The Real M'Kay," "Morgan Rattler," and "Tibb's Eve" came in for explanation, and we think that most English audiences would here require an interpreter. No one knows the derivation of the phrase "Tibb's Eve"; it implies the day that never comes and is a sort of Irish synonym for "the Greek Kalends." "The Real M'Kay" is used as an expression of commendation which may be compared to the street boy's phrase, "a bit of all-right." The phrase had its origin in the Spanish title of "Réal" or Royal granted to a scion of a famous Irish house. The name of Morgan Rattler, a well-known smuggler, is used as a type of cleverness not necessarily coupled with honesty. Of many examples of Ulster humour we quote the following. "Coming into hospital one day," says Professor Byers, "I overheard a patient say to another, 'Is your chicken soup thin?' The reply came at once, 'Ay, the bird only walked through it,' to which the first answered, 'Maybe it was on stilts.'" The people, especially the bucolic people of Ulster, do not differ from the inhabitants of other parts of the world in their belief in charms as a preventive of, or cure for, disease. We are told that in some places in the north of Ireland the moment a medical attendant pronounces the disease to be erysipelas a "charmer" is brought to the child. A patient suffering from mumps has to put on a donkey's bridle with the bit in his mouth and being led blindfolded to a stream or well is made to drink water three times in the name of the Trinity, the charmer meantime repeating an incantation. The ritual seems to be complicated but the value of suggestion is doubtless enhanced by making the patient submit to a good deal of trouble. Dread of the power of the evil eye still exists in Ulster as does also faith in omens. Professor Byers is to be congratulated upon having put on record some of the poetic superstitions of a charming people. That jettatura still has force in northern Ireland, as in Italy or the Levant, will be something of a revelation, we fancy, to most of our readers.

BURROUGHS, WELLCOME, AND CO. *v.* THOMPSON AND CAPPER.

Mr. Justice Byrne delivered judgment on Dec. 14th in an action of some interest to medical men brought by Mr. H. S. Wellcome, trading as Burroughs, Wellcome, and Co., against the firm of Thompson and Capper, druggists. The object of the action was to restrain the defendants from passing off goods as of the manufacture of Burroughs, Wellcome, and Co. which had not been manufactured by them and particularly from selling, or offering for sale, any such goods under the name "tabloid" or "tabloids" and from infringing these the registered trade-marks of the plaintiffs. Evidence was given in the course of the trial of the selling of goods not of the manufacture of Burroughs, Wellcome, and Co. to persons asking for tabloids and bearing prescriptions in which further specification of the manufacture demanded was afforded by the use of the initials B. W. & Co. by the prescriber. As to this being wholly unjustifiable no question could arise but the real claim of the plaintiffs was for the declaration of their exclusive right to the use of the words "tabloid" and "tabloids," without any addition, as indicating goods of their manufacture. The establishment of such a right by them was denied by the defendants, and behind this lay the question whether the words "tabloid" and "tabloids," registered by the plaintiffs as their trade-marks, were to remain upon the Trade-marks Register or were to be struck off in accordance with the defendants' cross-action to that effect. The judgment of Mr. Justice Byrne was in favour of the plaintiffs upon all points. He granted them an injunction against the defendants independently of the question of registered trade-mark. With regard to the trade-marks he refused to order their removal from the register and he granted the plaintiff firm a certificate to that effect. The case has some important professional bearings. One of the main grounds of attack on the trade-mark "tabloid" was the allegation that a proportion of the public did not know that the word was the property of a firm. It was shown in evidence by the defendants that Burroughs, Wellcome, and Co. advertised only to the medical profession and pharmaceutical trade, no facilities therefore being given to the public for gaining knowledge of the trade name in its proprietary connexion. It was also shown that some dispensers when supplying "tabloids" have removed the makers' label and affixed their own—a still more obvious reason for the ignorance of the public as to the property of Burroughs, Wellcome, and Co. in the word "tabloid." There are a few circumstances in which the dispenser is entitled to exercise his judgment concerning a prescription but the substitution of one drug for another, or of imitations for proprietary articles of accepted reputation, is not one of those circumstances. The medical man is accustomed to depend upon the pharmacist for a faithful discharge of the obligations of the written prescription, a consideration which no doubt determined the attitude of certain leading members of the pharmaceutical profession, and the President, Vice President, and several members of the Council of the Pharmaceutical Society appeared to give evidence in favour of Burroughs, Wellcome, and Co. For the reasons implied above we congratulate Burroughs, Wellcome, and Co. upon the result of the action. Their intent to approach the public through the medium of the medical profession only was used against them in a manner which could but enlist for them the sympathies of all practitioners.

ARGON IN ATMOSPHERIC AIR.

AN interesting communication was made recently to the Paris Academy of Science on the above subject. M. Moissan reported that he had followed up the researches of M. Schloesing who had already determined the proportion of argon existing in certain specimens of air. By utilising the property which calcium possesses of absorbing at one and the same time the oxygen, the nitrogen, and all the impurities which are found in atmospheric air, and by the use of a special apparatus of which he had already given a description to the Academy, M. Moissan had been able to estimate the amount of argon found in the air of Paris, of London, of Berlin, of Vienna, of St. Petersburg, and of Athens. In all these towns the amount was identical. The same proportion of argon was also found in samples of air taken in the Channel, in the Ionian Sea, in the Gulf of Naples, in the valley of Chamounix, at the Grands Mulets, and at the top of Mont Blanc. Air collected in the middle of the Atlantic appeared to be slightly richer in argon than that from other places. Calcium will combine with the hydrogen which is produced during reactions, forming a hydride which is not decomposed at a temperature of 600° C. All this illustrates the remarkable uniformity of the composition of the air. M. Moissan does not appear to refer to the question of small quantities of helion which may possibly occur in the air or as to what its behaviour would be when exposed to hot calcium. The results as regards argon are of interest and the observation that the air collected in the middle of the Atlantic appeared to contain a slightly greater proportion of argon than that from other places is probably in some way connected with its solubility in water and the great and frequent variations of atmospheric pressure to which the Atlantic ocean is liable.

THE MILK-SUPPLY OF FINSBURY.

A SPECIAL report has been printed in accordance with the instructions of the public health committee of the metropolitan borough of Finsbury in which the medical officer of health, Dr. George Newman, gives a very complete account of the position of the milk-supply of that place. Dr. Newman points out how difficult it is to trace the exact source of the milk sold wholesale or retail in the shops, so complex is the system by which the milk reaches the consumer from the point of production. And yet the importance of being able to do so is obvious when the question of milk and its relation to disease is considered. It is not easy to trace milk to its origin or to discover where or how contamination or adulteration originated. It appears that 90 per cent. of the cow's milk consumed in Finsbury is obtained from country farms and that 95 per cent. of the contributory farms are situated at a greater distance than 100 miles from London which, of course, means that the milk must be 12 hours *old* before it reaches the shops Dr. Newman states that as a general rule the country cowsheds from which this milk is derived are ill-lighted, overcrowded, badly ventilated, and badly drained. There is also little or no guarantee that the milk is derived from healthy cows free from tuberculosis. Again, the milk shop is sometimes found to be in anything but a sanitary environment. In Finsbury it is further stated that the adulteration of milk in 1901 was 22 per cent., that is to say, 7 per cent. higher than the average for all London. Dr. Newman therefore very properly calls attention to these facts and adds that in the face of them much remains to be done by the borough council in the direction of the control of the milk supply in Finsbury.

THE ROYAL INSTITUTION OF GREAT BRITAIN.

THE Christmas course of lectures at the Royal Institution will be delivered by Professor Ray Lankester, director of the natural history department of the British Museum. These lectures, which will be illustrated by lantern slides and adapted to a juvenile auditory, will deal with the subject of Extinct Animals and will be delivered on Dec. 29th and 31st, 1903, and Jan. 2nd, 5th, 7th, and 9th, 1904, at 3 P.M. on each day. Various extinct mammals will be described in the first four lectures, birds and flying reptiles in the fifth lecture, and newts, salamanders, and fishes in the sixth lecture. The Tuesday afternoon discourses will commence on Jan. 12th, when Professor L. C. Miall of the Yorkshire College, Leeds, will deliver the first of a series of six lectures on the Development and Tranformations of Animals. The Friday evening discourses will commence on Jan. 15th with an address by Lord Rayleigh on the subject of Shadows. The programme of the lecture arrangements up to March 26th, when the Easter recess will commence, includes a great variety of topics

TEETH IN THE TEMPORAL BONE OF HORSES.

THE occurrence of teeth in the temporal bone of horses formed the subject of an interesting communication by Mr. J. Bland-Sutton in the recent issue of the *Transactions of the Odontological Society of Great Britain*. This anomaly, which has been especially studied by French writers, has attracted but little attention in this country. The clinical features of these cases are briefly as follows. A swelling occupies the region of the temporal fossa and communicates with the surface by a sinus situated near the base of the ear. A probe passed along the sinus comes in contact with a hard body which invariably proves to be a tooth. The position of the sinus is of interest and it is not clear whether the sinus is congenital or arises as a consequence of suppuration as the tooth develops; indeed, Hensinger[1] regards the condition as due to persistent branchial fistula The teeth, varying in number from one to four, are misshapen and of a molar type and in some cases are so ill-formed as to come under the category of odontomes The condition in all recorded cases is unilateral and Mr. Bland-Sutton thinks that the malformation may be teratoid and allied to a somewhat similar anomaly in sheep. With regard to the origin of these teeth Mettams[2] suggests that the tooth-bearing cysts and the associated sinus are due to a developmental error in connexion with the first branchial cleft. A small portion has been separated off and along with it there is included parts of the tooth-bearing segment of the palato-pterygoid division of the arch From the point of view of pathogenesis, Mr. Bland-Sutton suggests that the abnormality should be studied in connexion with cervical teeth of sheep. These animals are liable to an anomaly in the neighbourhood of the ear which consists of a fistula opening near its base with the orifice invariably surmounted by an incisor tooth. In one specimen examined the tooth was lodged in a bony pedicle surrounded by mucous membrane of the same features as the gums, and the cutaneous recess in which it was accommodated presented in the aspect in contact with the tooth a number of processes resembling the papillæ in the sheep's lips The arrangement of the wool on the outer surface of this accessory lip was identical with that covering the normal lip of the animal. In another specimen examined by Gurt[3] two deciduous incisors were lodged in a miniature but unmistakeable mandible and associated with a tongue of corresponding size, while the fistulous tract communicated with the pharynx. These facts suggest that the teeth and associated structures are the remnants of an attached or parasitic fœtus and the cutaneous opening represents its mouth. A more careful examination is required of the anomaly of teeth in the temporal bone of the horse before any decisive statement can be made but the anomaly in the sheep seems to throw light on the pathogenesis.

THE COMPARATIVE GERMICIDAL EFFICIENCY OF DISINFECTANTS.

IT is time that some system of control should be organised with regard to disinfectant preparations by which some assurance could be given of their actual germicidal efficiency. There is no doubt that many proprietary disinfectant preparations on the market have exaggerated claims made for them in this respect and there are not a few which are practically worthless as germ destroyers. From time to time private investigations have been made on correct lines, in which the relative germicidal efficiency of a number of disinfectant preparations has been stated and the results have been of value. But it seems to us that what is wanted is a well-organised system by means of which the absolute efficiency of a disinfectant preparation can be guaranteed. The need of such an organisation is felt in America as well as in other countries and recently a practical paper upon the subject was read by Mr. B. R. Rickards at a meeting of the Massachusetts Association of Boards of Health, Boston, the details of which are of interest. The author's results may thus be summarised. Formaldehyde solution or formalin, although commonly supposed to be superior to carbolic acid as a liquid disinfectant, is really much inferior in equivalent per centum solutions. This fact is all the more striking when the high efficiency of formaldehyde as a gaseous disinfectant is considered. Formaldehyde is also a most efficient deodoriser The coal-tar proprietary compounds are, as a rule, very good disinfectants. They are not any better, however, than carbolic acid. Moreover, the composition of the proprietary articles may be varied and the purchaser be none the wiser. Carbolic acid is preferable in all cases when its odour and properties are not objectionable. The various colourless solutions put upon the market under fanciful names are, as a rule, of little value as disinfectants, their cost usually increasing in inverse ratio to their efficiency.

THE secretary of King's College Hospital has received a letter from the clerk to the Worshipful Company of Drapers stating that the company views with approval the proposal to move the hospital. The company has therefore voted the sum of £5000 from its corporate funds to the removal fund, conditionally upon the balance of the sum of £300,000 required being raised by voluntary contributions within the next 12 months. We can only hope that this generous offer will not be lost by any failure to raise the balance. A statement has just been authoritatively issued that the donor of the site for the new buildings of the hospital is the Hon. W. F. D. Smith, M.P., who is the chairman of the removal committee and treasurer of King's College. Mr. Smith wishes his donation to be associated with the memory of his father the late Mr. W. H. Smith who was for many years treasurer of the hospital, and the committee have accordingly decided to associate that gentleman's name with the central administrative block of the new hospital.

Dr. A. Marmorek, whose paper on Antituberculous Serum and "Vaccine" we published last week (p. 1642), has intrusted some of his serum to Dr. Arthur Latham for the purpose of an experimental trial of its properties in England. At present Dr. Latham has under observation in this connexion three cases at St. George's Hospital and two at the Brompton Hospital and next week he will have more cases. Dr. Latham thinks that in the course of a few months he and his colleagues will have collected sufficient evidence from the English cases in order to enable them to form a trustworthy opinion as to the advantages of the treatment. Dr. Latham will have the benefit of the personal advice of Dr. Marmorek who intends to come to London once a month; he was in London last week and gave the first injections himself before a number of Dr. Latham's colleagues.

THE British Dental Association has appointed a committee (in connexion with the inquiry at present taking place as to the alleged physical degeneration of the British race) to investigate the question of the alleged increase of dental caries. With this object the committee is anxious to examine British skulls and teeth of the last few centuries if possible. Early British skulls are to be found in museums and elsewhere in considerable abundance, but with the exception of Professor Thane's collection of skulls from Whitechapel (? plague pit) none of more recent date have been examined. The honorary secretary of the British Dental Association, 32, Leicester-square, London, W.C., would be grateful for any information concerning any such collection, if existent.

THE medical officer of health of the Cape Colony states that for the week ending Nov. 21st only 1 case of plague was discovered in the Colony—namely, that of a native male found dead on Nov. 15th in King William's Town. Plague-infected rats were found at East London, Knysna, Lady Grey Bridge, and on board a ship in Cape Town Harbour. As regards the Mauritius, a telegram from the Acting Governor received at the Colonial Office on Dec. 11th states that for the week ending Dec. 10th there were 76 cases of plague and 46 deaths from the disease.

THE King has approved of the appointment of Dr. John Mitford Atkinson (principal civil medical officer) to be an official member of the Executive Council of the colony of Hong-Kong.

Mr. Edward D. Madge, M.R.C.S. Eng., L.R.C.P. Lond., has been made an officer of the Order of the Crown of Roumania by H.M. the King of Roumania.

DONATIONS AND BEQUESTS.—The executors of the will of the late Mr. Robert Munn have paid to the Victoria Hospital for Burnley and District £8006, being the residuary estate of the testator bequeathed by him to the hospital.

THE FINAL REPORT OF THE ROYAL COMMISSION ON ARSENICAL POISONING.[1]

II.

IN our first article on this subject in THE LANCET of Dec. 12th, p. 1674, we dealt with Parts 1 to 3 of this report and gave an account of the Commission's conclusions regarding the toxicity of small quantities of arsenic taken for considerable periods together with beer and other articles of food and drink and its recommendations as to the tests which should be employed for the detection and estimation of arsenic in various substances. Part 4 of the report deals with the ways in which foods are liable to become contaminated by arsenic. When a question of risk of arsenical contamination arises the food manufacturer often argues that as the amount which could reach his products is in any case small there is no need for him to take special precautions in obtaining his glucose, colouring matters, or other ingredients which happen to be in question, and if small amounts of arsenic are found in his goods he urges that almost any substance will be found to contain arsenic, if enough of it is examined by modern methods.

The Commissioners have evidently been fully alive to objections of this kind in preparing Part 4 of their report, and they deal with the question in a thoroughly practical manner. Taking first ingredients of food, or substances used in food preparation, which are liable to contain arsenic, and next "finished foods," they show in each instance what is the extent of the liability to be arsenical, assuming carelessness or ignorance on the part of the manufacturer; what quantities of arsenic have been found in particular specimens; and what degree of purity is habitually obtained commercially or is readily attainable if reasonable precautions are adopted.

The Commission has obtained its information on the subject by hearing evidence of manufacturers, by correspondence with public analysts, and by instituting a series of inquiries at places of food manufacture, on which a report has been made by Mr. H. Hammond Smith. A number of foods obtained by the Commission have been examined for arsenic in the laboratory of Dr. G. McGowan and a large number of analyses made in the Government laboratory in connexion with brewing materials have also been reported to the Commission. The following substances are among those dealt with in the final report.

Mineral Acids.

Directly or indirectly sulphuric acid is used, sometimes in relatively large amount, in the preparation of a variety of foods.

The greater part of the sulphuric acid used for manufacturing and general purposes in this country is obtained [illegible] imported mainly from Spain and Portugal. [illegible] from certain mines, contain large proportion [illegible] manufactured, unless subjected to a de-arsenication process, is invariably arsenical. At works where a de-arsenication process is carried out the system of manufacture usually followed necessitates the production, in addition to the de-arsenicated acid, of an acid derived from the Glover tower which habitually contains a high proportion of arsenic. This, however, is not the case where the acid is prepared by synthetic processes which have been introduced in recent years. The sulphuric acid ("B.O.V.") supplied in 1900 by Messrs. Nicholson and Sons to Messrs. Bostock and Co. was contaminated by arsenic to an exceptional and enormous degree. As much arsenic as 1·45 and 1·9 of arsenious oxide per cent. has been estimated in certain samples of this acid. Chemical and other technical witnesses are agreed that de-arsenicating processes when thoroughly and uniformly applied at works where acid is obtained from pyrites produce an acid [illegible] de-arsenicated acid of the [illegible] when tested [illegible] only minute amounts of arsenic. Proportions of arsenic as high as from 2 to 3 parts per 1,000,000 (approximately 1-70th to 1-50th grain per pound of acid) can only occur if the de-arsenication is not properly carried out.

Commercial hydrochloric acid, as is well known, frequently contains arsenic. A recent specimen showed as much as 1·12 grammes of arsenious oxide per litre. The liability of this acid to be arsenical, however, is relatively small when it is prepared by "cylinder" and other processes in which special care is taken to employ pure sulphuric acid.

Glucose and "Invert" Sugar.

The glucose used by brewers is usually "solid." It is manufactured on a large scale at factories in Great Britain and a considerable quantity is also imported from America and Germany. The glucose used for confectionery, syrups, and other food purposes is generally "liquid" and is almost always imported. Solid and liquid glucose alike are liable to contain arsenic derived from sulphuric or hydrochloric acid, which are used in varying proportions (e.g., from 2 to 6 per cent.) in the "conversion" process by which the glucose is manufactured from starch. In view of the circumstances of the epidemic of 1900 it is unnecessary to insist upon the high degree of arsenical contamination of glucose which may be brought about by neglect of precautions regarding the quality of the acid used. Solid glucose manufactured by Messrs. Bostock and Co. in 1900 in several instances was ascertained to contain as much arsenic as three grains per pound, and even larger proportions of arsenic were estimated in a few specimens.

---

[1] Cd. 1848. Eyre and Spottiswoode, price 5½d.

With due attention to the purity of the chemical sub- [illegible]

But such instances have been few. Brewers' glucose is now generally free from arsenic, and the arsenic detected in some specimens has seldom exceeded 0·004 grain per pound. Similar conditions obtain in the case of the "invert" sugar which is used by brewers and sometimes also by manufacturers of cider and fermented "temperance drinks." About 3 per cent. of sulphuric acid is used in the preparation of this form of sugar.

Glycerine.

The observations of the report on glycerine are of interest. It is not generally known that as much as 3 per cent. of glycerine is sometimes added to cakes to keep them moist, or that this substance is used in certain meat extracts and confectionery. Large quantities of arsenic (one grain or even three or four grains per pound) were discovered a few years ago in several samples of glycerine. The attention then given to the subject has no doubt secured considerable improvement, but it is instructive that public analysts and others shortly after the 1900 epidemic reported objectionable quantities of arsenic in several samples of British and foreign glycerine sold for pharmaceutical purposes. A special test for arsenic ("Gutzeit" method) was introduced into the British Pharmacopœia in 1898.

The report notes, however, that—

> Doubts have been expressed as to the sufficiency of this pharmacopœial test. It has been stated that this test may fail to detect [illegible] vely small are neverthe- [illegible]

Colouring Matters: Caramel.

Oxide of iron, sold under various names, is the chief mineral colouring matter used in food. It is frequently obtained from the residue in the manufacture of Nordhausen sulphuric acid, and this is no doubt the reason for the considerable quantities of arsenic which have been found in some specimens. Coal-tar or "aniline" colours are in many cases prepared by the use of large quantities of crude sulphuric acid. Aniline colours used by sweet manufacturers have been found in some cases to contain as much as, or more than, half a grain of arsenic in the pound. Caramel has usually been found free from arsenic, but owing to the use of impure alkali in its preparation it is liable to be arsenical and as much as a quarter of a grain per pound has been reported in certain instances.

The report gives a useful warning (though on a matter somewhat outside the Commission's reference) as to the use of emerald green.

> Coloured salts o [illegible]
> are so notoriousl [illegible]
> never used in foo [illegible]
> articles which ma [illegible]
> use of emerald g [illegible]
> objectionable anc [illegible]
> year that he had [illegible]
> in green tapers thus coloured.

Other Chemical Substances used in Food.

Arsenic is well known as an impurity of commercial phosphates, which are largely used in baking powders, and of phosphoric acid, which is used in sugar refining and mineral waters. These substances have lately been purer as regards arsenic than was formerly the case. In some samples of commercial borax over one-third of a grain of arsenic in the pound has been reported. Considerable quantities of arsenic have been determined in certain samples of beer "regenerators," consisting mainly of alkaline carbonates used to treat beer which is going sour, and in other chemical substances used by brewers. In all these cases the Commission points out that satisfactory degrees of purity can be obtained commercially.

Malt.

> The liability of malt to be contaminated by arsenic was first recognised after the cause of the 1900 epidemic had been ascertained. Considerable amounts of arsenic have been reported by different witnesses to have been found in malt; as much as 1-20th grain and [illegible] seems certain that no arsenic was introduced otherwise than by way of the malt used.
>
> The question of arsenic in malt has lately received close attention from brewers and maltsters, and malts as a whole have in consequence improved in this respect. All our evidence goes to show that it is now commercially practicable to produce malt which either may be considered free from arsenic, or in which the amount of arsenic present is certainly less than 1 250th grain per pound (0 57 part per 1,000 000), and that most of the malt prepared during the past two years has been of this character.

Owing to the practical difficulties which have arisen the report gives a considerable space to the various ways in which it has been found possible to avoid the risk of malt becoming arsenical. Brewers and maltsters appear to hold that the products of combustion, whether of anthracite, gas coke, or oven coke, are essential to give a flavour to malt which is necessary for beer. Kilns constructed so that the malt-drying is wholly effected by means of heated air have lately been introduced but they have not got beyond the experimental stage. The Commission is not satisfied with the evidence that the products of combustion are necessary and recommends that the new systems should receive careful attention from brewers and maltsters who are about to erect new kilns. The use of gas coke for malt drying has been shown to be dangerous and has now been largely discontinued; oven coke, which is less objectionable, has also been discontinued to a considerable extent It cannot be said that the use of anthracite, as such, affords complete security. Much depends upon the selection of this fuel and on the extent to which pieces of pyrites, shale, and other "impurities" which contain arsenic are picked out of the anthracite at the colliery or by the maltster. The Commission had instituted an important inquiry into the presence of arsenic in malting anthracites and in "impurities" of anthracite seams with the aid of Mr. A. Strahan, F.R.S, of the Geological Survey, and others, and they indicate the principles which should guide maltsters in the proper selection of their fuel. The objections to relying solely on chemical analysis in the case of fuel, owing to the question of sampling and other practical difficulties, was emphasised by one of the Commissioners, Dr. Whitelegge, in the interim report of 1901 and the final report points to the more practicable method of picking out obvious impurities, such as pyrites, from anthracite as the first and most important step in the selection of satisfactory fuel.

The problem may also be attacked in other ways by "treating" the fuel with lime which prevents the arsenic from becoming volatilised, by placing lumps of limestone at the outlet of the kiln furnace, and by modifying the construction of the kiln so that the major portion of the hot air has not come into contact with the fire. In any case it is evident that frequent and thorough cleansing of the interior walls of the kiln is essential as the sweepings from these walls have been found to contain a surprising amount of arsenic which is liable to be volatilised again and carried to the malt on the drying floor above. The report notes that the drying of chicory roots in Belgium and France is in many respects comparable to malt drying and that the small amounts of arsenic (up to 1·100th of a grain per pound) reported in some samples of chicory are to be accounted for in this way.

Among "finished foods" which are liable to arsenical contamination the following are mentioned:—

Beer.

> The liability of beer to be contaminated by arsenic arises mainly through the use in brewing of arsenical glucose, invert sugar, and malt, or by the addition of arsenical invert sugar or glucose as "priming" after the wort has been fermented. The degree of contamination which

may arise in these ways is abundantly illustrated in our evidence. Since the 1900 epidemic and the appointment of this Commission close attention has been given by brewers to the exclusion of arsenic from these and other substances used in brewing and various precautions have been extensively adopted with the object of eliminating all risk of arsenical contamination of beer. We have referred in the first part of this report to evidence that, notwithstanding the general adoption of these precautions, beer has been occasionally met with in which notable amounts of arsenic (for example, 1-20th or 1-30th of a grain per gallon) have been found. But such instances at the present time may be considered quite unusual. We are satisfied from the evidence received during the later part of our inquiry that much of the beer sent out at the present time from breweries in this country may be regarded as free from arsenic and that arsenic, where detected, is usually in minute amount. All the chemical witnesses from whom we have recently had evidence (including responsible chemical advisers of breweries) have been agreed that it is commercially practicable to produce beer which uniformly shows less arsenic than 1-100th of a grain per gallon and in which as a rule any arsenic present is in much smaller proportion than this.

Golden Syrups; Treacle; Foods containing Glucose.

Golden syrup and treacle are usually prepared from cane or beet sugar by the addition of about 2 per cent. of sulphuric acid. Glucose is an ingredient of a large variety of foods. Certain syrups sold as "table syrup," "amber syrup," and the like, consist largely of liquid glucose. Jams and marmalade frequently contain from 5 to 10 per cent. of glucose and sometimes larger amounts. Glucose may be *mixed with honey or used as a basis for the manufacture* of "artificial honey." Certain kinds of sweets and confectionery, again, consist largely of glucose.

It is satisfactory to read that British manufacturers of golden syrup and treacle have been in the habit of taking strict precautions to obtain pure sulphuric acid and that many manufacturers have lately made a practice of testing the glucose which they use. But the report notes that—

> Certain manufacturers whose products contain large proportions of glucose appear to have considered it unnecessary to take any steps to assure themselves by analysis that their glucose was satisfactory in respect of arsenic, notwithstanding the circumstances of the epidemic of 1900.

Vinegar is specially noted, as at some factories the material from which the vinegar is made is raw grain (rice or maize) which has undergone a "conversion" process in which sulphuric acid is used in much the same way as in the manufacture of glucose.

Demerara sugar has been found to contain small quantities of arsenic, exceptionally 1-50th of a grain per pound, derived from chloride of tin used to colour West India sugar or from impure phosphoric acid.

In general, the Commission appears to have found little evidence of the presence of arsenic in *malted foods*. It draws attention, however, to a preparation termed "Carnos" made from yeast and malt culms obtained from a Yorkshire brewery. In four different samples of this food Dr. McGowan found from 1 25th to 1 6th of a grain of arsenic per pound.

Foods containing glycerine and colouring matters are also dealt with.

> Bole Armenia and other mineral colouring matters consisting mainly of oxide of iron are frequently added in considerable proportion in the preparation of a variety of foods—for example, sausages, anchovy preparations, cocoa, and certain kinds of sweets. Material quantities of arsenic may be contributed to these substances in this way. Thus Mr. Hehner in June of this year informed us that he had estimated approximately 1-20th or 1-25th grain of arsenic per pound in a "chocolate powder" largely sold in London at a cheap price, which had been contaminated by arsenic through the use of oxide of iron. He also estimated the arsenic in certain sweets, similarly coloured, at 1-30th grain per pound.

The Commission has found no evidence that the use of arsenical superphosphates as manure will cause contamination of ripe grain or roots. Other inquiries have been attended with reassuring results, especially an examination of enamelled cooking utensils from a large number of factories which indicates that the use of arsenic as an ingredient of the enamel has now been generally discontinued.

The report makes a series of recommendations in Part 5 as to the precautions which should be taken by manufacturers to exclude arsenic from foods. These comprise practical suggestions as to the substances to which attention should be given, as to the extent to which it is necessary that their purity should be controlled by analysis, and as to the significance which should be attached to any guarantees asked for or given in the case of ingredients such as sulphuric acid, glucose, malt, or colouring matters.

The Commission objects strongly to the giving of guarantees of "freedom from arsenic" based on crude tests or insufficient frequency of testing. The application of the Marsh-Berzelius test is now well understood and the Commission is of opinion that in all cases where arsenic is detected its amount should be estimated. For practical purposes it recommends certain limits, on the understanding that these do not represent standards of purity but merely of what should not be tolerated :—

> We think that no substance should be used as an ingredient of food which contains a larger proportion of arsenic than 1-100th grain per pound, or in the case of solutions 1-100th grain per gallon. In many cases (particularly glucose and malt) more stringent limits are now attainable commercially and should be insisted upon.

Incidentally the report draws attention to, and strongly condemns, the objectionable practice of selling chemical substances to food manufacturers under misleading or ambiguous trade names, giving as an example the sale to bakers of solutions of phosphoric acid, a cheap substitute for tartaric acid, under the name of "liquid tartaric acid." The use of oxide of iron and chloride of tin in food is regarded as objectionable and unnecessary. In one instance lanoline was employed as a substitute for cocoa-butter and owing to the use of arsenical sheep dip this substance is regarded as unsuitable for food purposes.

Review of the Present Means of Official Control over the Purity of Food and Recommendations for Improvements.

We are unable in this article to do more than call attention to Parts 6 and 7 of this report They comprise a very valuable summary of the present administrative machinery in relation to purity and adulteration of food and an exposition of its many defects. The recommendations which are made for improved administration by the Local Government Board and as to the establishment of food "standards" are eminently practical and moderate and deserve the careful consideration not only of the department concerned but also of all health officers and public analysts, who are frequently baffled by the present unsatisfactory state of the law. Practical proposals are also made for amending the law of "warranty" and for improving the "seizure" clauses of the Public Health Acts.

Pending an authority officially to prescribe standards the Commission advises that amounts of arsenic in food which exceed 1-100th of a grain of arsenic per gallon in the case of any liquid food, or 1-100th of a grain per pound in the case of any solid food, should insure penalty when prosecutions are instituted under the Sale of Food and Drugs Acts.

Doubt was originally expressed in some quarters as to the necessity of calling together a strong Royal Commission for the investigation of the subject of arsenical poisoning by way of beer and other food. But no one who reads this final report will now question that the Government were well advised. Lord Kelvin and his colleagues have fully justified the Commission's appointment by having undertaken a most thorough and valuable inquiry which could not have been carried out by other means, and the Commission by its report and recommendations has rendered an important service to the public.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A meeting of the Council of this Fund was held at Marlborough House on Dec. 14th, under the presidency of the Prince of Wales.

Lord Rothschild, the treasurer, in presenting the balance-sheet, said that the financial year had not ended, so that the accounts presented were incomplete. The amount received to Dec 10th was £71,033 8*s*. 3*d*. It spoke very highly for the honorary officials that the collection and distribution of the Fund were made at a cost of under £2000 a year.

Sir Henry Burdett said that he was glad to inform the meeting that the League of Mercy would be able to send a contribution of £10,000 to the Fund, which was £2000 more than last year and ten times as much as the amount given in the first year of the establishment of the league.

The report of the executive committee recommended this year the distribution of £99,000 to the London hospitals, making with the £1000 entrusted to the Fund by the London Parochial Charities for the convalescent homes, a total distribution of £100,000.

In presenting the report of the hospitals distribution committee Sir William S. Church referred to the great loss which the Fund had sustained by the retirement of Lord Lister as chairman of the distribution committee.

Sir William Church was elected to fill the post vacated by Lord Lister.

Sir SAVILE CROSSLEY then read the list of awards, which we hope to publish in full in an early issue.

We notice that the Bolingbroke Hospital at Wandsworth has been granted a donation of £1000. This hospital, which is in the centre of a congested population, has recently extended its accommodation and its expenses are necessarily great. Charing Cross Hospital has been given £2000 towards the rebuilding fund and the East London Hospital for Children £1600 to provide isolation and whooping-cough wards. Guy's Hospital, which receives an annual donation of £5000, has been granted £1000, and King's College Hospital, which also receives an annual grant of £1000, has been given the sum of £6500, £5000 of which are to be spent in the removal of the hospital to South London, which the committee views with great satisfaction. The London Hospital, with its annual grant of £5000, will receive a donation of £2000 and the Royal London Ophthalmic Hospital a donation of £2500. A sum of £2000 has been given to St. George's Hospital and one of £2000 to University College Hospital. A donation of £1000 has been granted to the West London Hospital, Hammersmith-road, W.

HIS ROYAL HIGHNESS, in moving the adoption of the report of the executive committee, said: My Lords and Gentlemen,—I beg to move the adoption of the report and in doing so to express my hearty concurrence with the recommendations of my committees and approval of the various grants and of the conditions upon which in some instances these have been made. You will, I know, join with my feelings of deep regret at our loss through the deaths of Cardinal Vaughan and Lord Rowton. We have also sustained a further serious loss in the retirement of Lord Lister who since the inception of the Fund has been chairman of the distribution committee. I trust that with improvement in his health we may again have the benefit of his valuable services. In reviewing the results of this year's work I have to admit that the hopes which I expressed 12 months ago that another £10,000 a year would be forthcoming, have not been fulfilled. But the year 1902 was an exceptional one, as a large sum was contributed specially as a coronation gift. We have, however, in addition to the sums set aside to be invested and those given in the form of investments, a considerable balance which can be utilised at the discretion of the general council. Upon this balance we have decided to draw for this year only in order that the amount for distribution among the hospitals may not be less than that of last year. We have not come to this decision without duly considering those two opposing principles one of which deprecates any encroachment upon our reserves, while the other advocates the expenditure of subscriptions with a view of relieving present necessity rather than of placing them to capital account. We are anxious not to go back in the work initiated by the King, and in the fulfilment of which I consider a sacred trust was confided to me. Our aim must be steady progress and to secure public confidence. I venture to draw attention to the enormous sums for which appeals are now contemplated by the London hospitals. According to my information, if we take only 12 hospitals out of more than 100, thus omitting many which are contemplating appeals, these sums amount to £700,000. This is exclusive of a probable appeal on behalf of St. Bartholomew's Hospital for a sum varying between £300,000 and £600,000. Hence the public must be prepared for appeals to provide over £1,000,000. And in addition to this there are other hospitals not included in this list, many of which have equally pressing needs. It is indeed a serious question whether some limit should not be put upon hospital extension works, and I trust that new schemes will not be undertaken by any hospitals without grave consideration of these heavy demands now being made on the charitable public. It is also a matter of regret to find that in the hospitals where the charges for maintenance were held to be too high no adequate reduction has yet been made. No doubt this matter will next year receive the close attention of the distribution committee. With regard to King's College Hospital I note with the utmost satisfaction its removal to South London. The importance of establishing in that vast population a large hospital with a medical school is known to all and I am glad that the decision seems to have met with general approbation. The amount allocated to the amalgamation of orthopædic hospitals is large but I fully concur with the distribution committee in its view of the great importance of establishing in London one first-rate orthopædic hospital. You will, I am sure, join with me in congratulating the League of Mercy on the steady progress made and the increased aid given by it to the Fund. It is a matter of satisfaction to find that the trustees of the London Parochial Charities continue to entrust us with the administration of the £1000 which they allot to convalescent homes. We are satisfied that in allocating these grants chiefly to convalescent homes connected with London hospitals we are acting in conformity with the views both of the supporters of the Fund and of the trust. The continued success of the Sunday and Saturday Funds proves that, as promised by the King, we have not trespassed upon their field of operations. The meeting of the Sunday Fund takes place to-morrow. We trust that the results may be in every way satisfactory and we look for continued coöperation with the other hospital funds. I have much pleasure in offering my congratulations to one of our honorary secretaries (Mr. J. G. Craggs) upon the honour conferred upon him by His Majesty, the patron of the Fund, in recognition of his valued services since the inauguration of the undertaking. I am directed by the King to express his high appreciation of the efficient manner in which the work of administration of the Fund has been conducted during the past year. His Majesty was especially pleased with the evident care and thought which had been bestowed upon the list of grants to hospitals and with the judicious decisions come to by the distribution committee. I have now great pleasure in moving the adoption of the report.

The LORD MAYOR of LONDON, supported by the Duke of FIFE, seconded the adoption of the report, which was carried unanimously.

A vote of thanks to the Prince of Wales, proposed by the Rev. J. GUINNESS ROGERS, was carried, to which HIS ROYAL HIGHNESS replied, and the proceedings terminated.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE annual general meeting of the Metropolitan Hospital Sunday Fund was held at the Mansion House on Dec. 15th, when the Right Hon. Sir JAMES T. RITCHIE, Lord Mayor, president and treasurer of the Fund, presided.

The report of the council for the year 1903 stated that—

> The thirty-first year of collecting this Fund has resulted, under the presidency of the Right Honourable Sir Marcus Samuel, Bart., Lord Mayor, treasurer, in a total of £64 975 12*s* 3*d*, the largest amount ever collected on Hospital Sunday since it was founded in 1872. The collections made in places of worship have again resulted in a record amount of £49,238 15*s* 9*d*, being an increase of £2907 13*s*. 4*d*. over those of last year. Their Majesties the King and Queen, with other

In proposing the adoption of the report, Alderman Sir JOSEPH SAVORY, Bart., M.P., said that the Fund owed a special debt of gratitude to the Rev. Prebendary Ridgeway of Christ Church, Lancaster Gate, to the Rev. Canon Fleming of St. Michael's, Chester-square, and to the Rev. Canon Pennefather of the Parish of St. Mary Abbots, Kensington, for the splendid contributions which they had made towards the total sum collected.

The CHIEF RABBI, in supporting the motion for the adoption of the report, referred to the loss which the Council had sustained by the death of Mr. A. L. Cohen.

Before putting the motion to the meeting the LORD MAYOR read an amendment which had been handed to him by the Hon. Stephen Coleridge with reference to the alleged use of the grants made by the Metropolitan Hospital Sunday Fund for the purpose of hospital school or college teaching.

Mr. RICHARD B. MARTIN, M.P., and the LORD MAYOR said that the awards of the Fund were made for the relief of the sick poor in the hospitals and not for the purposes of medical education.

Canon BASIL WILBERFORCE, who was to have seconded the amendment of the Hon. Stephen Coleridge, said that if this were so the amendment must fall to the ground.

A speaker in the body of the hall asked, if it were found that a hospital had made a grant to its medical school out of the sum awarded by the Metropolitan Hospital Sunday Fund, whether the amount so misused would be deducted by the Fund when it made its next distribution.

The LORD MAYOR replied in the affirmative.

The report was then adopted.

On the motion of the Rev. R. L. ALLWORK, seconded by Mr. R. W. DIBDIN, the council was re-elected with the addition of the following gentlemen to fill vacancies—Sir Marcus Samuel, Bart., the Rev. Frank Freestone, the Rev. J. Scott-Lidgett, and Mr Arthur T. West.

Sir SAVILE CROSSLEY, P C., M P., proposed, and Lord MEATH seconded, a vote of thanks to Mr. George Herring for his generosity which had assisted the Fund to secure the record amount of £64 975 This was carried with acclamation.

The ARCHDEACON of LONDON proposed :—

> That June 12th be fixed for Hospital Sunday of 1904 and that the cordial coöperation of all ministers of religion within the metropolitan area be again invited in the usual way.

In doing so he referred to the Royal visit to St. Paul's Cathedral this year which, he said, was due to the initiative of Sir Edmund Hay Currie, the secretary of the Fund. The Rev. W. H. HARWOOD seconded the proposition, which was adopted.

On the motion of Sir HENRY BURDETT, seconded by Sir WILLIAM CHURCH, an addition was made to Law IX. of the Constitution, which now reads :—

> In the event of a congregational collection made on Hospital Sunday being given to a particular hospital, dispensary, or institution, instead of being sent to the General Fund, the amount so sent shall be deducted from the grant made to that hospital, &c., and can in no case be included as forming part of the Fund. And in the further event of a partic[illegible] or institution fixing any day or days in the we[illegible] Hospital Sunday in any year for the purpo[illegible] of such institution upon the public it shall be an instruction to the committee of distribution, when determining the award to such institution, to take into consideration the amount received from such an appeal and the loss, if any, resulting therefrom to the Fund.

This was carried and the meeting terminated with a vote of thanks to the Lord Mayor who, in his reply, said he hoped that during his year of office the sum collected by the Fund would exceed any previous amount.

THE REPORT OF THE COMMISSION ON THE NATURE, PATHOLOGY, CAUSATION, AND PREVENTION OF DYSENTERY AND ITS RELATION TO TYPHOID FEVER.

WE have received a communication from Dr. George Turner, medical officer of health of the Transvaal, commenting upon the statements contained in the above-mentioned report. Our own summary of the report was published in THE LANCET of August 29th, p. 626. The main portion of Dr. Turner's letter is taken up with a judicially written estimate of the marked differences shown in the report between the opinions of Dr. W. J. R. Simpson and of Colonel J. Lane Notter, R A.M.C. Dr. Turner was sent in October, 1900, by Lord Roberts on a tour of inspection to all the camps situated between Pretoria and Komati Poort and Barberton and he was accompanied by Dr. Simpson and Colonel Notter. All that either of these authorities saw on the tour Dr. Turner saw and that at the same time, so that, to use his own words, "I can form a fair opinion as to which of them most accurately represents the facts." Speaking generally Dr. Turner agrees with Dr. Simpson. With regard to the objection taken by both Dr. Simpson and Colonel Notter to the prevailing system of removal of excreta by bucket Dr. Turner points out that no doubt water carriage is the best method of removal. But water carriage implies a supply of water "and that is precisely what is generally wanting in South Africa." As regards Lord Wolseley's "Soldier's Pocket Book," 1886, Dr. Simpson states that "it was the knell to the development of sanitary science and sanitary administration in the army as a prevention against disease." With this statement Dr. Turner thoroughly agrees. Dr. Turner next proceeds to take Colonel Notter's objections to Dr. Simpson's statements *seriatim* and here we give his own words.

Sanitary Condition of the Camps.

"Colonel Notter (p. 5) says : 'I consider the description of the camps to be greatly exaggerated. In my opinion, except in a few cases of camps occupied by colonial and irregular forces, the general sanitary state of the camps was good. ...... This has been intensified by the free employment of civil surgeons with the army in the field who have had no training whatever in sanitary science or preventive medicine.' This is in reply to a remark of Dr. Simpson (p. 56) as follows : 'The most crude notions and practices prevail which are contrary to the simplest elements of sanitary science. It requires very little descriptive powers to portray the results : polluted water-supplies, filthy latrines, covered with swarms of flies and uncovered with earth, excrement, polluted soil, manure heaps, and dead horses have been the usual accompaniments of camps where large numbers of troops have been located.'

In my opinion Dr. Simpson's general description is not exaggerated. Camps varied considerably as regards cleanliness and selection of position and those occupied by the colonial and irregular forces were not by any means always the worst. The civil surgeon did not always see that his tents were pitched with mathematical regularity and the whitening of the stones to mark out the paths left something to be desired, but as regards essentials it was different. The civil surgeon is just as likely to have received instruction in sanitary matters and is more likely to have had practical experience than is his military *confrère*.

I do not wish to infer that in bad camps all the errors enumerated in Dr. Simpson's general description were to be found but generally one or more of these avoidable errors were committed. The latrine pits were usually defective and no care was taken to prevent the dispersal of paper. At one camp I saw the dam side covered with pieces of paper which had been blown from a pit. On another occasion a regiment, to save the trouble of digging a pit, had actually used the furrow which carried the drinking water into a town. I did not actually see this but I had the evidence of two men who did see it and who told me of it independently and I have no reason to doubt the truth of their statements.

The selection of camps when on the march was often bad. A relative, a civil surgeon, spoke to his commanding officer about the imprudence of camping on the ground occupied by the Boers 24 hours previously as he knew that they had left several cases of enteric fever behind them. The reply was, 'What business is it of yours?' This was on the march and there may have been high strategic reasons for camping on a fæces-sodden soil. But in camps it must be different. I saw men camped out and and actually eating their food on the refuse heaps and within a few feet of a foul latrine. It would have been perfectly possible to have gone elsewhere and not far away. I saw the men camped out on ground on which the slop water of a hospital discharged and actually washing in the foul water. There was no earthly reason for this, there was more than ample room, yet this place of all others was selected. I accidentally ascertained that a rest camp had been formed near the railway. I suspected, from the elevation, that the town water could not reach it and made an examination. My surmise was correct. But water from a filthy sluit was laid on in readiness for the troops. A regiment which had been religiously filtering and boiling water might have camped there for the night and have suffered soon after from typhoid fever, and then the uselessness of filtration, the effects of soil and the agency of flies would have been called into requisition.

The disposal of carcasses was particularly bad. Colonel Notter (p. 4) tried to throw the onus of this on the Civil administration of Pretoria. But the jurisdiction of the municipality of Pretoria does not extend over the whole of the Transvaal and the nuisance was not by any means confined to Pretoria. I have frequently seen carcasses in water furrows and spruits which must have been there for days. As regards Pretoria, the civil administration was carried out under martial law and the duty of burying carcasses was imposed on the civil administration. Sometimes the number reached 200 in one day. The civilian population of Pretoria could not possibly furnish anything like 200 animals; 90 per cent. of those buried belonged to the military. And when it is remembered that nearly all the draught animals had been commandeered it is marvellous that so much was done; the work was not rendered any easier by the fact that sick animals were driven into the municipal area to die in order that the civil administration might bury them. The difficulty of burning carcasses has, in my opinion, been exaggerated. The process requires little fuel, provided that the carcass is previously opened and the bowels are exposed to the air for 24 hours, then very little brushwood and a small quantity of paraffin will cause it to burn easily. In fact, I burned many carcasses in this manner.

The Water-supply.

This, in my opinion, is the most important of all questions as regards typhoid fever. Colonel Notter writes (p. 139): 'Very stringent orders were issued to all units that the water used for drinking purposes should be boiled before distribution and for this purpose Sawyer's boilers were provided and an extra fuel allowance issued.' And again (p. 4*a*): 'The statement that it was the general exception for water to be filtered or boiled by regiments I consider to be far from the real facts Commanding officers were most keen on this point and in my experience it was rather the *exception to find water not boiled or filtered*' This to me is the most surprising assertion in view of the knowledge I possess of what Colonel Notter actually saw while he and Dr. Simpson accompanied me to Komati Poort and Barberton. Dr. Simpson's statement, so far from being exaggerated, is under-stated. I did not see any Sawyer's boilers; they may have been provided at a later period or in other districts but the troops were all supplied with filters.

If asked whether the water was filtered we were generally assured that it was and I have no doubt that the assurance was given in good faith. But we always inspected the filters. On one occasion a screwdriver had to be fetched to open the box, the bougies were all wrapped in the paper in which they left the shop, and the original packing was in the box. This box had been transported God knows how many miles and had never been used. More than once the filter was broken and I remember one was popular on that account because it filtered easily. In some regiments the filters were put up and anyone who liked to have filtered water could filter for himself. In very few regiments was the filtration properly supervised. In one case we were informed that the commanding officer had 'a fad about water,' that 'he had water on the brain.' Anyway he had come up from Natal and was then at Waterval Boven and he had not had any cases of typhoid fever. But even when water was filtered no attempt was made to insure that the men did not drink foul water. I am speaking now of camps not on the march.

At Skinner's Court was a well of fine water which could be raised by means of a pump. Dr. Simpson and I watched the men fetching water in their bottles. I did not see a man fill his bottle at the clean well, but several did so from a polluted spring which was about 50 yards nearer the camp and this went on *right in front* of the commanding officer who was sitting outside the tent. At Daspoort camp, where pure water was provided, at great expense in pipes from the Pretoria source, Dr. Simpson and I saw the men, about a dozen, fill their bottles from a leak in an irrigation furrow which contained the foulest water possible. I drew the attention of an officer to the fact and he remarked 'Yes, they will do it.' I went to see this camp because so many cases came into hospital from it Two of the cases described by Lieutenant-Colonel D. Bruce (p. 29) came from this place.

Dr. Simpson (p. 70) describes the discovery of the supply of foul water to the Pretoria railway-station as the result of an accident. It was hardly that. I had arranged that weekly samples of water should be taken from the reserve and at some ten or 20 points in the town should be analysed. This I did in order to be able to note and to inquire into any slight variations which might appear in the analyses. For three consecutive weeks I noticed that the sample taken at the station differed slightly from the others and that the difference increased. As the station tap was so situated that it was subjected to a negative pressure during the daytime I made arrangements with the town engineer to examine the pipes so as to be certain that there was no leakage. We then found that the tap in question was supplied, not from the covered reservoir which contained the same water as the town supply, but from an open sluit which was polluted. A clean supply by means of tanks was provided but the tap, to the best of my knowledge and belief, was never removed although I wished it done. Colonel Notter (p. 4) apparently objects to the remarks of Dr. Simpson as to the water-supply of West Fort as he has no knowledge of it, but the objection is rather far fetched, because at that time Colonel Notter was in hospital and Colonel Bruce was occupied in the laboratory, so that unless the work of the commission was to stop only Dr. Simpson remained to carry it on.

Even when pure water was laid on it was frequently so managed as to become polluted. For instance, water had to be pumped both to the Yeomanry Hospital and to another large hospital, because they were situated at too great a height for the town water to reach them Therefore wells were formed on the mains in such situations that at night, when the pressure was at its best, they were filled and water was pumped from these wells to cisterns in the hospital. I noticed that in the weekly analyses the number of micro-organisms per cubic centimetre instead of being below 100 amounted to thousands and, therefore, I inspected these supplies. In one instance the well was uncovered on the level of a very dusty road over which much traffic passed. In the other instance the well was in a shed; it was imperfectly covered, and on the cover were remnants of bread and meat. I concluded that a pet dog had been fed there. I may be wrong but the pieces of meat and bread were there and had no business there.

Colonel Notter (pp. 4-6) says, 'Too much is made of failure to put a guard on a particular disused water-supply. It must be remembered that the men were getting one night in bed per week owing to the onerous duties then prevailing.' He evidently misunderstands Dr. Simpson. If the paragraph mentioned in the note is referred to it will be seen that though the remarks are applied to the Daspoort incident it was in the second paragraph made generally applicable. I can substantiate Dr. Simpson's remark. I cannot remember any attempt being made to prevent men from drinking bad water. It may have been done, but although I was constantly making inquiries I never came across a case. As regards the Daspoort incident an officer and many engineers were working day and night within a few feet of the place at which the men took the foul water. The plea cannot hold water.

A civil surgeon, a relative, informed me that he had seen a guard placed at a drift from which an engine was pumping water. No one was allowed on the banks. Well and good, but he added that the men bathed and washed their *clothes above the place.*

But there was even a grosser case of neglect. During my investigations as to the origin of certain cases of enteric fever I became convinced that they were caused by drinking soda-water from a particular factory. I had a sample analysed and the analyses showed not only that the soda water was not prepared from the town water-supply but that the water was polluted. I immediately wrote to the principal medical officer of the forces and was informed that he had been aware of the fact for ten days. I am speaking from memory —it may have been a week; but in any case the time was quite long enough to have informed me of the fact so that I might have closed the factory. Dr. Simpson subsequently was good enough to make a bacteriological examination of the well water; the result is given in Appendix V., p. iii. The typhoid organism was separated. The sample said to have been analysed by the military had been taken from the Yeomanry Hospital. This I could not understand, because I had gone through the merchant's books and there was no entry of any sale to the Yeomanry and, when questioned, he denied any sale to them. Besides, there had not been any marked number of cases of enteric fever in the hospital which could have arisen during the patients' stay there. If the soda water at the Yeomanry Hospital came from the factory in question (the Trevenna) then the cases I supposed to be due to the consumption of that water were attributable to some other cause. The bacteriological examination had not then been completed. I went to the hospital and was assured that the water came from Travenna, but when I saw the invoices it was evident that all had come from a factory which used Pretoria town water and which I had recently closed because the premises were dirty and not well kept. The Travenna books show that considerable sales had been made to the military and I endeavoured to trace these and to have them destroyed, but found that the whole supply had been sent down the Durban line Therefore, not only had the military omitted to report the matter to me or to close the factory, but they had omitted to take such an obvious precaution as to stop the issue of the soda-water which they had in store. It was impossible from the army statistics to find if the soda-water in question had caused any appreciable amount of disease, because they are useless for that purpose, but judging from the effect it had produced in Pretoria it cannot have been harmless. The factory was closed until Pretoria water was laid on and the proprietor, who acted very innocently as regards the unfortunate occurrence, made a donation of £20 to the hospital, I am entirely of Dr. Simpson's opinion as to the value of the army hospital statistics. They may serve the purpose for which they were designed but they are useless for sanitary purposes. We spent hours trying to obtain any useful information from them and failed. It is important for preventive purposes that there should be speedy and accurate knowledge of the places in which disease originates.

Without offering any opinion as to the method he proposes to provide a sanitary service for the army, such a service is essential. Of course there are brilliant exceptions, but, broadly speaking, the officers of the Royal Army Medical Corps know less of sanitary matters than the general practitioner. How can it be otherwise? Moreover, any officer who has any sanitary *fads*, to quote Lord Wolseley, is very apt to have them soon knocked out of him. I could give a very glaring instance of this but it would serve no good purpose and might embarrass deserving men. I have not the least wish to depreciate the value of the Royal Army Medical Corps as a body and I feel certain that Dr. Simpson has no wish to do so. We quarrel with the system, or want of system, and not with the officers. The same remark applies to the Royal Engineers. No man possessed of ordinary common sense could travel over the railway line at the time that I did, when it was frequently destroyed, and see the stupendous work carried out by the Engineers and the rapidity with which it was accomplished without being struck with admiration. At the same time I do not think they are usually first-class sanitary engineers. It is not their vocation."

Dr. Turner concludes his letter by saying that he has "a few exceptions to take to Dr. Simpson's views as to the way in which typhoid fever was spread." As regards the frequency with which it is conveyed from person to person directly or at least not through the agency of water, upon which both Dr. Simpson and Colonel Notter lay stress, Dr. Turner agrees that this method of infection, though not common, probably accounted for many cases at Bloemfontein. The agency of flies he considers as unimportant; for instance, the highest proportion of admissions for enteric fever occurred in June, 1900, when the admissions were 1·16 per cent. of strength. But June is midwinter and the flies then are not troublesome.

Looking Back.

FROM

THE LANCET, *SATURDAY*, DEC. 17, 1825.

OBSERVATIONS [1]

Upon "IGNOTUS *on the Medical Profession*," *and* "NEOTEMERE *in reply*." By a SURGEON, APOTHECARY, and MAN-MIDWIFE.

To the Editor of THE LANCET.

SIR,—In turning over some old numbers of the Repository the other day, (a somewhat morbid taste, you will say,) or what a pastoral friend calls "chewing the cud," I chanced to stumble upon two papers in Nos. 87 and 89, written by a wag, yclept or ycleping himself "*Ignotus*," and a third in No. 93, professing to be a reply to the above-mentioned two by, evidently, a *no wag*, under the *nom de guerre*, "*Neotemere*," a name under which it behoves his god-fathers and god-mothers, for the edification of all good Christians, to explain and etymologize.

He (Ignotus) tells us, that "*professional men carry their stock in trade within their crania, or skulls*."—God help them!—'tis a small store-house, and often too but slenderly stocked; besides, does he mean to assert that a lawyer, carries all his briefs, a divine, his texts, and a physician, his prescriptions under his hat? Pshaw! the thing is impossible.

"*A surgeon*," *he goes on to state*, in "common with, &c. &c. may claim his station amongst those who exchange intellectual exertion for money, but whence the apothecary derives his claim," &c. &c —whence? why, from the same source. Is not his intellectual exertion?—what can be more so than pill making, plaster spreading, gallipot scraping, and draught shaking, accompanied, as it may be, by humming an Irish melody, spouting Shakspeare, quoting Horace, or mouthing Byron? Would that he had been accustomed to such intellectual pursuits, he could not then, after his affectation of euphony, too, have been guilty of another mis quotation; "the rose will smell as sweet," &c.—bah!—"the flower we call a rose, by any other name would smell as sweet;" let him look at Romeo and Juliet, in Stevens's edition.

"*The art of the apothecary*," we hear, is "that of sending in medicine," and "the most wonderful mystery—what becomes of it all?" but this is far from his only art. There is the art of supplanting a pre occupant, or rival—the art of worming into a family—the art of coaxing nurses—the art of frightening your patient, but, at the same time, keeping out his physician—the art, too, of calling him in *in time*; there is also the art of emulsionizing a cough, and of cordializing a pious spinster, who would not drink a tea-spoonful of "Booth's best" to save her soul, but will swallow alcohol by the ounce from the doctor, to the decided detriment of her body; in short, there is the whole art of acting, looking, walking, talking, and riding, the apothecary—the mystery is soon solved; woe to the clergy were theirs as soluble; that is, palatable medicines are swallowed, nauseous ones smelt, and those of ambiguous character returned with the empty bottles.

"*Walking the Hospitals*," it is true, generally amounts to an amble, and now and then to a run; but the book of disease, like that of nature, is, we all know, written in large and legible characters, and "he who runs may read."

"*A sentence in the pharmacopœia*," is no such trifle; the very first one in the preface would puzzle many an Eton boy, although, I contend, that it is quite as classical and humane to bring a *book to an anvil* as a *nose to a grindstone*: and where, let me ask, is the physician, who can *always* translate his own prescriptions?

P.S. These lucubrations, although anonymous, will of course be admitted into THE LANCET. Should any doubt exist as to the authenticity, respectability, or responsibility of the writer, the Court of Examiners at the Hall will perhaps be able to set these matters at rest, if it is just mentioned, that he is the identical X T.N. who, not many years since, was a little puzzled with their *drawings* of medicinal plants, and who then and there took the liberty of suggesting, that as medical botanists made use of their *noses* as well as their *eyes*, it might be as well to have the said drawings *scented* according to the individual odour of the plants they represented.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8207 births and 5553 deaths were registered during the week ending Dec. 12th. The annual rate of mortality in these towns, which had been 17·4, 17·6, and 18 6 per 1000 in the three preceding weeks, further rose last week to 19·2 per 1000. In London the death-rate was 18·9 per 1000, while it averaged 19·4 in the 75 other large towns. The lowest death-rates in these towns were 6·3 in Grimsby, 8·8 in Leyton, 10·6 in Hornsey, 10·8 in Walthamstow, 13·1 in King's Norton, 13·3 in Barrow-in-Furness, 13·4 in South Shields, 13·8 in Tottenham, and 14·0 in Stockton on-Tees; the highest rates were 25·2 in Oldham, 25·4 in York, 25 7 in Reading, 26·2 in Burnley, 26·5 in Plymouth, 29 6 in Middlesbrough, 30 2 in Wigan, and 32 0 in Merthyr Tydvil The 5553 deaths from all causes in these towns last week included 422 which were referred to the principal infectious diseases, against 436 430, and 402 in the three preceding weeks, of these 422 deaths, 121 resulted from measles, 97 from whooping cough, 67 from diphtheria, 67 from diarrhœa, 30 from scarlet fever, 37 from "fever" (principally enteric), and three from small pox. No death from any of these diseases occurred last week in Hornsey, Tottenham, Bournemouth, Southampton, Burton on-Trent, Grimsby, St Helen's, South Shields, or Newcastle on Tyne, while the highest death rates from the principal infectious diseases were recorded in Willesden, Great Yarmouth, Warrington, Bury, Burnley, Preston, Rotherham, and York The greatest proportional mortality from measles occurred in Willesden, Great Yarmouth, Warrington, Bury, Preston, Rotherham, and York, from diphtheria in Coventry and Merthyr Tydfil, from whooping cough in Brighton, Wolverhampton, Aston Manor, Bootle, Rochdale, Burnley, Leeds, Newport (Mon), and Swansea; and from diarrhœa in Burnley The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns Two fatal cases of small pox were registered in Gateshead and one in Birmingham, but not one in any other of the 76 large towns The Metropolitan Asylums hospitals contained 32 small pox patients on Saturday last, Dec 12th, against 51, 47, and 40 on the three preceding Saturdays, two new cases were admitted during the week, against five, five, and three in the three preceding weeks The number of scarlet fever cases remaining under treatment in these hospitals and in the London Fever Hospital, which had been 1824, 1832, and 1770 at the end of the three preceding weeks, had further declined to 1717 at the end of last week, 173 new cases were admitted during the week, against 191, 157, and 161 in the three preceding weeks The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 325, 399, and 358 in the three preceding weeks, rose again last week to 417 and were 47 above the number in the corresponding period of last year The causes of 67, or 1 2 per cent, of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Leicester, Nottingham, Salford, Leeds, and in 39 other smaller towns, the largest proportions of uncertified deaths were registered in Hastings, Reading, Birmingham, King's Norton, Coventry, Liverpool, St Helen's, South Shields, and Gateshead

---

[1] Excerpts only are transcribed.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 17 4, 18 7, and 20 0 per 1000 in the three preceding weeks, further rose to 22 4 per 1000 during the week ending Dec 12th and was 3 2 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 16 4 in Edinburgh and 17 0 in Paisley to 25 8 in Glasgow and 29 3 in Greenock The 735 deaths in these towns included 34 which were referred to measles, 15 to diarrhœa 13 to whooping cough, six to scarlet fever, two to diphtheria, two to "fever," and one to small pox In all, 73 deaths resulted from these principal infectious diseases last week, against 61, 62 and 53 in the three preceding weeks These 73 deaths were equal to an annual rate of 2 2 per 1000, which was 0 7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of measles, which had been 13, 17, and 22 in the three preceding weeks, further rose to 34 last week, and were all registered in Glasgow The deaths from diarrhœa, which had been 20, 22 and 12 in the three preceding weeks, rose again last week to 15, of which nine occurred in Glasgow, two in Edinburgh, and two in Dundee The fatal cases of whooping cough, which had been seven nine, and seven in the three preceding weeks, increased again to 13 last week and included five in Glasgow, three in Aberdeen, two in Edinburgh, and two in Paisley The deaths from scarlet fever, which had been four, two, and one in the three preceding weeks, rose again last week to six, of which five were registered in Glasgow The fatal cases of diphtheria which had been seven, five, and four in the three preceding weeks, further declined last week to two, both of which occurred in Glasgow. The two fatal cases of fever were recorded in Greenock and the death from small pox was registered in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 136, 148 and 138 in the three preceding weeks, rose again last week to 192, and were 51 in excess of the number in the corresponding period of last year The causes of 31, or more than 4 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN

The death-rate in Dublin, which had been 24 5, 24 8, and 27 5 per 1000 in the three preceding weeks, declined again to 24 6 per 1000 during the week ending Dec 12th During the past four weeks the death rate has averaged 25 4 per 1000 the rates during the same period being 17 7 in London and 17 2 in Edinburgh The 179 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 21 from the number in the preceding week and included 11 which were referred to the principal infectious diseases, against nine, 11, and 13 in the three preceding weeks; of these, seven resulted from whooping cough, two from diarrhœa, one from measles, and one from "fever," but not any from small pox, scarlet fever, or diphtheria These 11 deaths were equal to an annual rate of 1 5 per 1000, the death rates last week from the principal infectious diseases being 1 2 in London and 0 8 in Edinburgh. The fatal cases of whooping cough, which had been two, three, and five in the three preceding weeks, further rose last week to seven The 179 deaths in Dublin last week included 33 of children under one year of age and 57 of persons aged upwards of 60 years; the deaths of infants showed a marked decline from the number in the preceding week, while those of elderly persons were slightly in excess Eight inquest cases and seven deaths from violence were registered, and 56, or nearly one third, of the deaths occurred in public institutions The causes of eight, or nearly 5 per cent., of the deaths registered in Dublin last week were not certified

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE

IN accordance with the provisions of His Majesty's Order in Council of Oct. 9th, 1903, the seniority of the undermentioned Fleet Surgeons has been antedated to the dates shown against their names viz —William Rogerson White, dated Oct. 2nd, 1888, Steward Frazer Hamilton, dated July 29th, 1889, Henry Anthony Wills Richardson, dated Sept 21st 1890, Edward Wentworth Luther, dated Sept 30th 1890, Everard Home Saunders dated Oct. 1st, 1890, William Henry Patterson dated Dec 7th, 1890, William Edward Bennett, dated Dec 9th, 1890, Archibald McKinlay, dated March 2nd, 1891, Alfred Patterson, dated Oct 26th, 1891, John Dudley, dated Jan 29th, 1892, Henry Lawrence Crocker, dated Sept 5th, 1892, George Sprey Smith, dated April 27th, 1893, Leonard Henry Kellett dated April 27th, 1893, John Davey Henwood, dated May 7th, 1893, James Crawford Dow, dated June 4th, 1893, Charles Edward Geoghegan, dated Sept 23rd, 1893; George Despard Twigg, dated Sept 27th, 1893, Thomas Edward Henry Williams, dated Nov 19th, 1893, Standish Thomas O Grady, dated Dec 6th, 1893, Howard Todd, dated Jan. 6th, 1894, Alexander Livingston Christie, dated Feb 20th, 1894, Charles James, dated March 12th, 1894, Francis Austen Jeans, dated May 21st, 1894, Charles William Buchanan Hamilton, dated July 15th 1894, John Speare Lambert, dated July 25th, 1894, Horace Ximenes Browne, dated August 11th, 1894, Arthur William May, dated August 21st 1894, Alexander John James Johnston, dated Nov 16th, 1894, James O Brien Williams, dated Nov 16th, 1894, Samuel William Vasey, dated Dec 19th, 1894; Richard Edmund Biddulph, dated Oct. 1st, 1895, William Tait, dated Oct 1st, 1895; Joseph Crowley, dated Oct 1st, 1895, William Manley Lory, dated March 31st, 1896, William Spencer Lightfoot, dated March 31st, 1896, John Jeffreys Dennis, dated Oct. 2nd, 1896, Frederick John Lilly, dated Oct 21st, 1896, John Lloyd Thomas dated Nov 9th, 1896; Horatio Septimus Richard Sparrow dated Feb 26th, 1897, Anthony Kidd dated Feb, 26th, 1897, James Henry Beattie, dated Feb 26th, 1897; Edward James Biden, dated

August 25th, 1897; William Eames, dated August 25th, 1897; Charles William Sharples, dated August 25th, 1897; William George Kynaston Barnes, dated Feb. 27th, 1898; William Henry Norman, dated August 28th, 1898; James McCardie Martin, D.S O., dated August 28th, 1898; William Maxwell Craig, dated August 28th, 1898; Timothy Joseph Crowley, dated Feb. 26th, 1899; Donald Templeton Hoskyn, dated Feb. 26th, 1899; Robert Howard Nicholson, dated Feb. 26th, 1899; John Leslie Barrington, dated Feb. 26th, 1899; Percy William Bassett-Smith, dated March 26th, 1899; George Welch, dated March 26th, 1899; Edward Bridges Townsend, dated May 30th, 1899; Patrick Brodie Handyside, dated May 30th, 1899; Edward John Morley, dated August 21st, 1899; Hugh Winckworth Macnamara, dated August 21st, 1899; Joseph Henry Whelan, dated August 21st, 1899; Edgar Ralph Dimsey, dated August 21st, 1899; Joseph Reville McDonnell, dated August 21st, 1899; and Hamilton Meikle, dated August 21st, 1899.

Consequent on the above the undermentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon in His Majesty's Fleet, with the seniority shown against their names, viz.:—Henry Harries, dated Feb. 11th, 1900; Edmund Corcoran, dated Feb. 11th, 1900; James Lawrence Smith, M.V.O., dated Feb. 11th, 1900; John Henry Thomas, dated Feb. 11th, 1900; John Dowson, dated Feb. 11th, 1900; Henry Frederick Iliewicz, dated Feb. 11th, 1900; Jeremiah Sugrue, dated Feb. 26th, 1900; Alexander Gascoigne Wilde, dated August 21st, 1900; Harold Rochester Osborne, dated August 21st, 1900; James Macdonald Rogers, dated August 21st, 1900; Chatworth Louis Nolan, dated August 21st, 1900; Harold Frederic Dale Stephens, dated August 21st, 1900; Edward Copley Ward, dated August 21st, 1900; William Robert Minchin Young, dated August 21st, 1900; Herbert William Gibbs Doyne, dated August 21st, 1900; George Albert Dreaper, dated August 21st, 1900; Alexander Fleming Harper, dated August 21st, 1900; Hubert William Austin Burke, dated August 21st, 1900; Edward Robert Drummond Fasken dated August 21st, 1900; James Charles Francis Whicher, dated August 21st, 1900; Alexander Gordon Andrews, dated August 21st, 1900; Arthur Stanley Nance, dated August 21st, 1900; Evan St. Maur Nepean, dated August 21st, 1900; Henry Erskine South, dated Feb. 16th, 1901; Alfred Matthew Page, dated Feb. 16th, 1901; Alfred Cropley, dated Feb. 16th, 1901; John Jenkins, dated Feb. 16th, 1901; Horace Elliott, dated Feb. 16th, 1901; Robert Forbes Bowie, dated Feb. 16th, 1901; William Edward Home, dated August 20th, 1901; Richard Aubrey Fitch, dated August 20th, 1901; Henry Bullen Beatty, dated August 20th, 1901; William Spry, dated August 20th, 1901; Percy Edmund Maitland, dated August 20th, 1901; James Joseph Walsh, dated August 20th, 1901; John Moore, dated August 20th, 1901; Cyril James Mansfield, dated August 20th, 1901; Robert Hickson, dated August 20th, 1901; John Lowney, dated August 20th, 1901; Frederick Walter Stericker, dated Feb. 18th, 1902; William Wenmoth Pryn, dated Feb. 18th, 1902; Graham Egerton Kennedy, dated Feb. 18th, 1902; Jerome Barry, dated Feb. 18th, 1902; Alfred John Pickthorn, dated Feb. 18th, 1902; John Andrews, dated Feb. 18th, 1902; Henry John Hadden, dated Feb. 18th, 1902; Vidal Gunson Thorpe, dated Feb. 18th, 1902; Edward Henry Meaden, dated Feb. 18th, 1902; Alfred Ernest Weightman, dated August 20th, 1902; James Walter Octavius Underhill, dated August 20th, 1902; Frederick James Burns, dated August 20th, 1902; Daniel Joseph Patrick McNabb, dated August 20th, 1902; Charles Strickland, dated August 20th, 1902; James Mead France, dated August 20th, 1902; John Menary, dated August 20th, 1902; Walter Godfrey Axford, dated August 20th, 1902; George Thomas Broatch, dated August 20th, 1902; William Bett, dated August 20th, 1902; Frederick Augustus Brice, dated August 20th, 1902; John Walter Slaughter, dated August 20th, 1902; George Henry Foott, dated August 20th, 1902; John Douglas Hughes, dated Feb. 28th, 1903; William John Colborne, dated Feb. 28th, 1903; John Hutton Stenhouse, dated Feb. 28th, 1903; Joseph Agnew Moon, dated Feb. 28th, 1903; Robert Hardie, dated Feb. 28th, 1903; Cornelius Bradley, dated Feb. 28th, 1903; George Trevor Collingwood, dated Feb. 28th, 1903; Richard Miller, dated Feb. 28th, 1903; John Edwin Coad, dated Feb. 28th, 1903; Hubert Holyoake, dated Feb. 28th, 1903; George Wilson, dated Feb. 28th, 1903; Walter Bowden, D.S.O., dated Feb. 28th, 1903; Octavius William Andrews, dated June 2nd, 1903; James Bradley, dated August 27th, 1903; George Hewlett, dated August 17th, 1903; George Alexander Walters, dated August 17th, 1903; William Gordon Stott, dated August 17th, 1903; Charles Sharman Woodwright, dated August 17th, 1903; Jonathan Shand, dated August 17th, 1903; and William Arthur Whitelegge, dated August 17th, 1903. Also the seniority of the undermentioned Staff Surgeons has been antedated to the dates shown against each, viz:—Johnston Hamilton Acheson, dated Feb. 22nd, 1896; John McElwee, dated Feb. 22nd, 1896; D'Arcy Harvey, dated Feb. 22nd, 1896; Reginald Thomas Alexander Levinge, dated Feb. 22nd, 1896; John Christopher Ferguson, dated Feb. 22nd, 1896; Edward Pain Mourilyan, dated Feb. 22nd, 1896; Charles Marsh Beadnell, dated May 2nd, 1896; Ernest Courtney Lomas, D.S.O., dated Oct. 21st, 1896; Robley Henry John Browne, dated Nov. 9th, 1896; Edward Butler Pickthorn, dated Nov. 9th, 1896; John Falconer Hall, dated Nov. 9th, 1896; Lawrence Bidwell, dated Feb. 21st, 1897; Edward Henry Hodnet de Courtmacsherry, dated Feb. 21st, 1897; Walter James Bearblock, dated Feb. 21st, 1897; William Hackett, dated Feb. 21st, 1897; Charles Geekie Matthew, dated Feb. 21st, 1897; Thomas Austen, dated Feb. 21st, 1897; Joseph Chambers, dated Feb. 21st, 1897; Percy Vaughan Jackson, dated August 22nd, 1897; Alfred Harold Lissant Cox, dated August 22nd, 1897; Alexander Maclean, dated August 22nd, 1897; Robert Hill, dated Nov. 6th, 1897; Frederick William Parker, dated Feb. 21st, 1898; George Goss Borrett, dated Feb. 21st, 1898; Walter Henry Skinner Stalkartt, dated Feb. 21st, 1898; George Alexander Stuart Bell, dated Feb. 21st, 1898; John Ambrose Keogh, dated Feb. 21st, 1898; Henry William Finlayson, dated July 28th, 1898; Frederick Fedarb, dated July 28th, 1898; Richard Cleveland Munday, dated July 28th, 1898; Edward Carter Cridland, dated July 28th, 1898; Frank Bradshaw, dated July 28th, 1898; Matthew Joseph O'Regan, dated July 28th, 1898; Richard Francis Bate, dated July 28th, 1898; Arthur Gaskell, dated Oct. 31st, 1898; Thomas Christopher Meikle, dated Feb. 11th, 1899; Thomas Cudlip Wood, dated Feb. 11th, 1899; Horace Bruce Marriott, dated Feb. 11th, 1899; Norman Lloyd Richards, dated Feb. 11th, 1899; Ernest Alfred Penfold, dated Feb. 11th, 1899; Ernest James Finch, dated Feb. 11th, 1899; John Kirkup Robinson, dated Feb. 11th, 1899; Hugh Clift, dated Feb. 11th, 1899; Ernest Albert Shaw, dated March 26th, 1899; Francis Herbert Aylen Clayton, dated March 26th, 1899; Frederic James Abercrombie Dalton, dated March 26th, 1899; Edward Sutton, dated March 26th, 1899; and Arthur Reginald Bankart, M.V.O., dated May 5th, 1899.

The following Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's fleet, with the seniorities shown against their names—viz.: Edward Cooper, dated Nov. 11th, 1899; Charles Samuel Facey, dated Nov. 11th, 1899; William Ernest Marshall, dated Nov. 11th, 1899; Montague Louis Bouchier Rodd, dated Nov. 11th, 1899; Herbert Lloyd Penny, dated Nov. 11th, 1899; Arthur Edward Kelsey, dated Nov. 11th, 1899; Henry Baker Hall, dated May 11th, 1900; Henry William Gordon Green, dated May 11th, 1900; Thomas Edward Honey, dated May 11th, 1900; George Thompson Bishop, dated May 11th, 1900; Edgar Fairbank Mortimer, dated May 11th, 1900; Beauchamp Frederick Parish, dated May 11th, 1900; Frederick Albert Capps, dated May 11th, 1900; Percival Marshall May, dated Nov. 15th, 1900; Christopher Louis White Bunton, dated Nov. 15th, 1900; Frederick Davidson Lumley, dated Nov. 15th, 1900; Edward Thomas Meagher, dated Nov. 15th, 1900; Henry Edward Tomlinson, dated Nov. 15th, 1900; Arthur Sydney Gordon Bell, dated Nov. 15th, 1900; James William Wilcocks Stanton, dated Nov. 14th, 1901; Henry Newport Stephens, dated Nov. 14th, 1901; Morris Charles Langford, dated Nov. 14th, 1901; Thomas Williams Philip, dated May 16th, 1902; Lancelot Kilroy, dated May 16th, 1902; Arthur Harry Hingston Vizard, dated Nov. 14th, 1902; Paul Hohling Mills Star, dated May 15th, 1903; Edwin Swainson Miller, dated May 15th, 1903; and Oswald Rees, dated May 15th, 1903.

In accordance with the provisions of His Majesty's Order in Council dated May 13th, 1901, commissions of the rank and date shown have been restored to the following gentlemen, formerly in His Majesty's navy, who have been placed on the list of volunteers for service in the event of war or emergency: James Henry Dawe, Surgeon, dated Feb. 18th, 1886; Philip Nicholas Randall, Surgeon, dated Feb. 21st, 1890; George McGregor, Surgeon, dated Feb. 11th, 1891; Frank Ernest Rook, Surgeon, dated

May 16th, 1894; and Eric Danvers Macnamara, Surgeon, dated Nov. 29th, 1897.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. Riordan retires on retired pay (dated Dec. 12th, 1903).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain E. Gray, 2nd Cheshire Royal Engineers, Railway Volunteers, to be Surgeon-Captain (dated Dec. 12th, 1903).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Cinque Ports: Surgeon-Captain J. B. Berry to be Surgeon-Major (dated Dec. 12th, 1903). 4th Lancashire: The undermentioned officers resign their commissions:—Surgeon-Captain W. McClelland (dated Dec. 12th, 1903). 6th Lancashire: Francis William Bailey to be Surgeon-Lieutenant (dated Dec. 12th, 1903).

Rifle: Galloway: Surgeon-Captain J. Cowan resigns his commission (dated Dec. 12th, 1903). 1st Volunteer Battalion th [illegible] Charles Percival Allen to be [illegible] Dec. 12th, 1903). 3rd Voluntee [illegible] Regiment: Charles Richardson White to be Surgeon-Lieutenant (dated Dec. 12th, 1903). 3rd (Dundee Highland) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Major W. Kinnear is borne as Supernumerary whilst commanding the Black Watch Volunteer Infantry Brigade Bearer Company (dated Dec. 12th, 1903). 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highl [illegible] W. A. Pride to be Surgeon-Ca [illegible] h Middlesex (London Sc [illegible] be Surgeon-Lieutenant- [illegible]

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The London Companies: Major H. W. Dodd resigns his commission, with permission to retain his rank and to wear the prescribed uniform on retirement (dated Dec. 12th, 1903); Lieutenant H. Fulham-Turner to be Captain (dated Dec. 12th, 1903).

SOUTH WALES BORDER VOLUNTEER INFANTRY BRIGADE.

Field-Marshal Sir Evelyn Wood, commanding 2nd Army Corps, sanctions an extension of service until Jan. 31st, 1906, in the case of Brigade-Surgeon-Lieutenant-Colonel P. E. Hill, V.D., South Wales Border Volunteer Infantry Brigade.

DEATHS IN THE SERVICES.

Major Langton Philip Mumby, R.A.M.C., on Dec. 1st at Spring Garden Lodge, Gosport, in his forty-third year. The deceased, who was the youngest son of the late Colonel Charles Mumby, received his medical education at Westminster Hospital Medical School, where he took a high place in the various class examinations. He graduated M.B. of London University in 1884, having obtained the M.R.C.S. and L.S.A. qualifications during the previous year. In 1892 he took the D.P.H. of Cambridge. After holding resident appointments at Westminster Hospital Dr. Mumby entered the Medical Department of the Army in 1886 and served with distinction in the North-West Frontier campaign of 1897 (mentioned in despatches).

Correspondence.

"Audi alteram partem."

AN APPEAL BY THE UNIVERSITY OF LONDON IN SUPPORT OF MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—We venture to ask your aid in giving publicity to an appeal which is now being issued by the Senate of the University of London for funds to build and to endow an Institute of Medical Sciences under the control of the University. Owing to the great changes which have taken place in medical education of late years, due to the increasing attention given to the teaching of the scientific subjects, it has become impossible for each medical school out of the income derived from the fees of students to build, to equip, and to maintain the laboratories, fitted with costly apparatus, which are necessary for modern scientific teaching. It has long been felt that a great improvement would be effected if instruction in certain subjects could be given, not separately in a number of medical schools, but in one or more central institutions controlled by one authority.

The Royal Commission appointed to consider the charter for the proposed teaching university in London reported as follows:—

> The teaching of physics, chemistry, biology, anatomy, physiology, ... pharmacology ...... should be concentrated into one or two *institutions*.
>
> It can hardly be doubted that considerable improvement in medical education would result from this [illegible] time and expense and concentratio [illegible] be set free from what must now be [illegible] enabled to devote all their energ [illegible] subjects of medicine and surgery, which in all their various branches have largely developed of late years.

The Statutory Commission appointed to frame the statutes of the reconstituted University adopted the recommendation of the former commission and embodied it in the following statute:—

> [illegible]

The faculty of medicine, a body consisting of 350 recognised teachers of the University, having ascertained the views of the teachers of the medical schools, recommended the Senate to establish an Institute of Medical Sciences for the teaching of physics, chemistry, biology, anatomy, and physiology.

It is because the Senate believes that at the present moment there is a most favourable opportunity of obtaining that centralisation *in the teaching of these subjects which has been* so much desired that it appeals for funds to help the University to carry out this project. If London is to maintain the position which it has hitherto held as a centre of [illegible] that money for these objects [illegible] recognised [illegible] to meet a [illegible] the United Kingdom in which there are such opportunities for the study of medicine and surgery as in London. The importance of its hospitals, the immense number of patients suffering from every kind of disease who come from all parts for treatment, and the presence of distinguished physicians and surgeons as teachers, have combined to render London one of the most celebrated schools of [illegible]

The public is indeb [illegible] ly for a supply of men comp [illegible] and the private needs of the community, but also for many of those discoveries which have of late done so much for the advancement of medicine and surgery. The nation has therefore a very direct interest in the efficiency of medical education; and now that the needs of London in this respect have been made known it is hoped that the University will obtain from the citizens of the metropolis the support which it requires [illegible] providing the space required for the teaching of the prelimary scientific subjects, would henceforth be able to devote all their resources to the care of the sick and to research into the causes of disease, to an improved knowledge of which future advances in medical and surgical treatment must be due.

We confidently commend the present appeal of the University to those who are in a position to help it forward by donations or bequests. Donations and applications for copies of the appeal and for further information should be sent to the honorary treasurers at 35, Clarges-street, W. For the convenience of donors the payment of a donation may be extended over a period of three years.

We are, Sirs, yours faithfully,
ROSEBERY,
Chancellor.
P. H. PYE SMITH,
Vice Chancellor.
ARTHUR W. RUCKER,
Principal.
J. K. FOWLER,
Member of the Senate.
H. T. BUTLIN,
Dean of the Faculty of Medicine.
Honorary Treasurers of the Appeal Fund.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—You will pardon my revival of this subject, but the recent polemic in THE LANCET in which Dr. A. G. Auld and Dr. Harry Campbell participated respecting this reflex may be regarded as an adequate excuse for my intrusion. I do not concur with Dr. Campbell who combats the theory of Dr. Auld—viz , that the lung reflex is an independent reflex and not dependent on the action of the inspiratory muscles. I presume that I am correct in assuming that Dr. Campbell does not deny the existence of the lung reflex but merely questions its mode of genesis. We do not deny the phenomenon known as the knee-jerk although we may remain undecided whether it is a true spinal reflex or accept the interpretation of Gowers that it is due to the direct effect of the concussion or the sudden stretching upon the muscle itself which is in a condition of slight tonus. Dr. Campbell presents the unconditional inspiratory dyspnœic theory in explanation of the lung reflex, ignoring, as Dr. Auld puts it, "that the lung has an *inherent* power of dilating apart from the breathing forces or atmospheric pressure." The theory of Dr. Campbell is certainly ingenious and is fully elaborated in his excellent work on "Respiratory Exercises," to which I owe many valuable suggestions, notably those relating to the splanchnic vaso-motor mechanism which have enabled me to develop an important clinical sign which I have called the "cardio-splanchnic phenomenon." The Campbell theory of the genesis of the lung reflex of dilatation may be contravened, as I view it, by succinct reference to the counter reflex of *lung contraction.*[1] The latter reflex is evoked by forcible percussion in the nature of a concussion blow and manifests itself in brief by the translation of a resonant into a dull percussion sound. This method of concussional percussion when executed during the time the Roentgen rays are traversing the chest demonstrates the gradual darkening of a definite area of lung contiguous to the region percussed and impresses one as though the lung were trying to squeeze the air out of the air vesicles. After the lapse of several seconds the specified lung area resumes its normal brightness. If the Campbell theory is correct—viz., that lung dilatation ensues as a result of cutaneous irritation which reflexly excites the inspiratory muscles to action, why is it that in a manœuvre necessary to elicit the lung reflex of contraction when cutaneous irritation is more pronounced lung contraction and not dilatation ensues? Surely dyspnœa as a resultant of lung collapse (the lung reflex of contraction) would be a more reasonable assumption than air-hunger as a concomitant of lung dilatation. Why is it that the reflex of lung contraction does not occur if the nasal mucosa has been cocainised? I may add that recently I have succeeded in bringing both lungs into a condition of contraction by medicamentous applications to the nasal mucosa and that after such applications none of the conventional manœuvres necessary to induce the lung reflex of dilatation proved operative. I have reserved for future consideration, for a work on asthma now in course of preparation, further reference to this important subject.

That the lung reflexes are quite independent of any dyspnœic activity of the thoracic musculature is made evident by my contribution on the physiological action of amyl nitrite.[2] I demonstrated that in a certain percentage of persons the inhalation of this drug will cause a diminution of the transverse diameter of the heart, a fact made evident by the x rays. Insomuch as amyl nitrite is regarded almost as a specific in inhibiting the distress of angina pectoris the theory of Heberden that angina is a cramp of the myocardium must be wrong and the theory of extreme tension of the ventricular walls in consequence of acute dilatation seems to be corroborated by the action of the drug upon the heart What appears to be more apposite in this connexion is the fact that after inhalation of amyl nitrite a limited patch of lung dulness over the manubrium sterni may be evoked. This patch of dulness obtained by percussion may involve the entire manubrium and extend to the right as well as to the left side. The dulness in question is almost never reproduced after an immediate second inhalation of the drug. The lung dulness is dependent on circumscribed collapse of lung, a veritable lung reflex of contraction, and may be dissipated at once by tapping the epigastrium which provokes the counter reflex of dilatation. In some persons inhalation of the drug evokes dull areas in other thoracic regions but the dulness over the manubrium is almost constant. I recall an individual with progressive muscular atrophy in whom both lung reflexes could be elicited notwithstanding loss of electric irritability of the muscular structures of the chest. The elicitation of the lung reflexes through the nose and elsewhere and their inhibition by definite manœuvres prompted me to conclude several years ago in a publication that they were dependent on reflex irritation of broncho-constrictor and broncho-dilator nerves which I hypothesised to exist in the vagus. The recent experimental observations of Dixon and Brodie[3] appear to confirm my original conclusion based on purely clinical investigations.

The number of cutaneous visceral reflexes has by no means been exhausted. More recently I have demonstrated the existence of liver, stomach, and intestinal reflexes. I believe that the epoch-making investigations of Head will prove an incentive to the discovery of other reflexes which will not only subserve a useful purpose in diagnosis but will also suggest many valuable therapeutic measures and elucidate many therapeutic methods which have had heretofore no substantial reason for their existence other than empiricism.

I am, Sirs, yours faithfully,

ALBERT ABRAMS

THE NEED FOR FURTHER REFORMS IN THE DEPARTMENT OF ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—The many points of interest and importance not only to teachers of anæsthetic administration but also to the governing bodies, medical staffs, and patients of the great hospitals of the United Kingdom which are clearly set forward in Dr. Frederic Hewitt's letter on this subject to THE LANCET of Dec. 12th (p. 1683) form my apology for adding a few remarks and suggestions to those which have already appeared.

A practical knowledge of the administration of anæsthetics has never been, and is not at the present time, demanded by the various universities in their examinations for medical degrees, and, as far as the public are concerned, the possession of a university degree by a medical man is no certificate to them that he has ever read a book on the subject, attended a lecture on anæsthetics, or administered to a single case in his whole previous life. One of the first steps in procuring the advance which is now being claimed for the position of the anæsthetist is to insure a proper training in anæsthetics for every medical student before he receives legal registration and is qualified to practise. More than a year and a half ago the Royal Colleges of Physicians and Surgeons in London inserted a course of practical and theoretical instruction in anæsthetics into their curriculum; their action is bearing good fruit in insuring proper training to those who obtain the Conjoint diplomas, and it lies with the graduates of the various universities to bring pressure to bear upon them to follow his example.

A medical practitioner who has not held a resident post including the work of anæsthetic administration at a hospital is unlikely, to say the least, to have had sufficient practical experience in this branch of the medical art to undertake it in his practice with safety to the public. Many believe that because their obstetric patients take chloroform quite easily in small doses its administration for surgical operations is quite a simple and safe affair. There never was a greater mistake. The physiological state during the period of childbirth is for many reasons peculiarly favourable to the exhibition of chloroform and the anæsthesia required is very light, whilst for surgical cases great experience is necessary to meet the requirements of the various types of patient, both healthy and in every pathological state, in addition to the modern conception of complete anæsthesia entertained by the operator. Most operating surgeons are so thoroughly cognisant of these facts that they dread the performance of any operation without the aid of a specially trained and experienced anæsthetist and, in view of the gradual disappearance of the "major shadow" of high mortality from the surgical procedure itself, as pointed out by

Dr Hewitt, and the emergence of the "minor shadow" of mortality from anæsthesia from its former obscurity, this is a very right and reasonable fear Unsuitable environment and the frequent lack of needful accessories in private practice will always render it inferior in the treatment of disease to the hospital, and as the hospital sets the highest ideal of treatment and advice in other special departments so the hospital must be the means of educating the public to the proper estimation of the services of the skilled anæsthetist

The ideal most surgeons desire and the governing bodies of the hospitals should be urged to adopt is this that no anæsthetic should be administered within their walls excepting by, or under the personal supervision of, a specially chosen anæsthetist To provide the requisite officers and experience the appointment of resident house anæsthetists at all the teaching hospitals should be made, preferably from the ranks of former house physicians and surgeons The lectures demonstrations and supervision of the whole department should be in the hands of one or two competent medical officers with staff rank according to the size of, and particular work required by, the institution

I am, Sirs, yours faithfully,
H Bellamy Gardner

THE ADMINISTRATION OF CHLOROFORM TO MAN AND TO THE HIGHER ANIMALS.

To the Editors of The Lancet

Sirs —Dr A D Waller's lecture on the Administration of Chloroform to Man and to the Higher Animals, published in The Lancet of Nov 28th, p 1482 surely contains a warning which the medical profession should be slow to neglect Remembering the immense advances made during recent years in almost every department of medicine and surgery towards exact knowledge it is surprising that the administration of anæsthetics is still an empirical operation Who, amongst even the more skilled anæsthetists, is prepared to say what is the exact composition of the vaporous mixture which he is administering to his patient? The present loose and inaccurate method of producing anæsthesia is unnecessarily dangerous in the hands of a careful but less skilled anæsthetist If a surgeon were given the choice of being assisted at an operation by a skilled surgical assistant or a skilled anæsthetist would he not almost invariably choose the latter

Dr Waller's remarks upon the "open" method of giving chloroform—much vaunted by Edinburgh men as the safest—show with equal clearness the great danger and the great extravagance of this method It is disconcerting but wholesome to realise so plainly that the patient may at one inspiration receive an overwhelming at others a minimum dose of chloroform the amount inspired depending largely on that uncontrollable factor—the character of the respiration The majority, perhaps, of anæsthetics are given by those who, from whatever reason, do not hold themselves to be amongst the more skilful anæsthetists It appears to me high time that some form of apparatus should be obtainable which will accurately determine the quantity of anæsthetic vapour actually being inspired, will permit such quantity to be regulated with precision, and will also supply continuously air which has not been previously respired by the patient

Junker's inhaler is no doubt an attempt in this direction Although analyses of the composition of the mixture it supplies have been published, the mixture yielded must necessarily vary greatly in composition and other dangers of the apparatus are well known Probably some form of apparatus, such as that of Dubois could be made in a portable form suitable for what may be called clinical work Some such apparatus seems to have been suggested by Vernon Harcourt and tried by some anæsthetists A description of the apparatus—which does not seem to be supplied by surgical instrument makers—and accounts of experience with it are not easy to find It may be concluded that the time has arrived when the administration of anæsthetics should cease to be an art and become a branch of exact science

I am, Sirs, yours faithfully,
W J Lindsay, M A., M D , D P H. Cantab

Bromley, Kent, Dec 10th, 1903

RECURRENT OVARIAN CYSTOMA AND ABERRANT ACCESSORY OVARIAN STRUCTURES

To the Editors of The Lancet

Sirs —I am glad that I have succeeded in drawing Mr J D Malcolm's special attention to the unique table published by Spencer Wells showing the causes of death of those who recovered from completed ovariotomy for cystoma and I hope that the profession also will take note of it, for I am convinced that the matter is of more than ordinary importance In none of these cases could any sign of malignant disease be detected before, during, or after the operation, although it is certain that every case was carefully scrutinised *ad hoc* by the keen eyes of Spencer Wells, who would naturally not care to spoil his operation results by including malignant cases in his list Indeed, at this period, if, after opening the abdomen the disease was found to be malignant the operation was usually abandoned It is necessary to recollect, for the proper appreciation of this matter, that the great majority of Spencer Wells' patients were still alive when his table was published very many of them having been comparatively recently operated on, for in the earlier years of his career far fewer operations were done than subsequently It is no use speculating as to what maladies these persons might have died from, for we have no information whatever on the subject Therefore for the purpose of ascertaining the causes of death of those who died after completed ovariotomy these surviving cases must be completely ignored Statistical conclusions on this subject resting on any other basis can only be *pour rire* Spencer Wells' 1000 completed ovariotomies were done between the years 1858 and 1880 The final inquiries as to after results were made in 1881, when the state of affairs was as follows —449 reported themselves well in 1881, 11 were well in 1880 but did not respond to subsequent inquiry, 85 were well in 1872 but did not respond to subsequent inquiry, 55 were well when last heard of ten years previously but did not respond to subsequent inquiries, 51 were not heard of after the operation 651 were therefore alive or were not known to be dead in 1881, 127 of the remainder died after operation of the first 500 cases, 105 others died after operation of the second 500 cases, and 117 died after recovery from the completed operation—total, 1000

Of the 117 patients who were known to have subsequently succumbed 29 died from unknown causes, 43 died from various cerebral cardiac, or pulmonary affections unconnected with the operation, seven died from abdominal or pelvic disease not further specified, six died from recurrent ovarian cystoma, 32 died from malignant disease of various parts In 19 of these 32 cases the seat of the disease is not stated in the other cases the parts affected were the peritoneum in three the uterus in three the ovarian pedicle in two, the rectum in two cases and the lung the liver, and the kidney each in one case It is distinctly stated, with regard to six of these 32 cases, that the operation was bilateral and it probably was so in several of the others Now from the analysis it will be seen that the causes of death of those who recovered after completed ovariotomy were known only in 88 cases, and of these 32 were ascribed to malignant disease or 36 per cent, which is an extraordinarily high percentage

Wishing to avoid any appearance of exaggeration, I purposely omitted from my estimate the four cases in which malignant disease supervened at very brief intervals after the operation, but these may very well have been instances of acute traumatic malignancy caused by the operation, such as we occasionally see in other parts of the body after operative procedures for the removal of non malignant tumours Although the evidence furnished by Spencer Wells' ovariotomy cases as to the great frequency of subsequent malignant disease seems to me to be of the most complete and convincing description, I have not relied on it solely, or even chiefly, for proving my thesis The cumulative evidence of modern experience, to which I alluded in my last letter in your journal, is of an equally convincing and undeniable kind and permits of not the slightest doubt being entertained as to the exceptional frequency of malignant disease after operations of this kind

In conclusion, it appears to me that Mr Malcolm has been rather unfortunate in the somewhat antiquated statistical data, as to the comparative frequency of malignant disease of the ovaries, which he has cited from Greig Smith's work. Leopold and Schroeder's series of cases are absolutely worthless for this purpose, since they comprise a large number of specially selected malignant cases sent to the clinic for this very reason. It is quite inadmissible to compare cases of this kind with Spencer Wells' ovariotomies from which all malignant cases had been rigorously excluded. I selected the Kelly series of 138 ovarian tumours because this is the only considerable series of such tumours known to me in which the diagnosis had been verified by microscopical examination. With a larger total the percentage of malignant disease would no doubt have accorded closely with my own results, derived from the analysis of 804 primary ovarian tumours under treatment at four of the largest London hospitals, of which only 6·3 per cent. were malignant. Olshausen's and Pfannenstiel's data support me in this contention, for of 293 ovarian tumours from the former's clinic 21 were malignant, or 7·1 per cent.; and of the latter's 400 cases 22 were malignant, or 5·5 per cent.

I am, Sirs, yours faithfully,

Clifton, Bristol, Dec. 4th, 1903. W. ROGER WILLIAMS.

THE ASSURANCE OF UNDER-AVERAGE LIVES.

To the Editors of THE LANCET.

SIRS,—The interesting and suggestive letter of "Actuary" in THE LANCET of Dec. 5th, p. 1617, has, I regret to see, produced no comment from those members of the profession who are best qualified to speak on this somewhat special branch of medicine.

There is no doubt that it is wrong to accept a sub-standard life at ordinary rates on the "limited payment" scale. The tendency, however, has been to accept such lives with a smaller addition than would be required were the policy a "whole life" one. This is done on the ground that the flaw in the applicant—be it gouty tendency, cancerous family history, &c.—will not probably affect him until all the payments have been made, and examiners are apt to fall into the error of supposing that the office is then safe. But as "Actuary" points out, this is far from being the case and is another proof, if such were required, that these sub standard lives should not be accepted at ordinary rates for the "limited payment" scale. What I would venture to ask "Actuary" is how he arrives at the conclusion that the addition on the "limited payment" scale should be greater than that on the "whole life" basis. The point appears to me to be a new one and of such importance as to require further elucidation.

I am, Sirs, yours faithfully,

Temple, Dec. 14th, 1903. R. L. GUTHRIE.

A CASE OF TRAUMATIC ANEURYSM OF THE GLUTEAL ARTERY TREATED BY INCISION OF THE SAC AND LIGATURE OF THE ARTERY DURING INTRA-PERITONEAL COMPRESSION OF THE INTERNAL ILIAC.

To the Editors of THE LANCET.

SIRS,—At p. 601 of THE LANCET of August 29th Dr. Alan H. Muir has an article on this subject, in the remarks on which Mr. W. F. Brook says: "The credit of having been the first to devise and to perform this operation belongs to my friend Mr. W. H. Battle who in 1898 published a case which he successfully treated in this way at the Royal Free Hospital. So far as I know this is the only case on record." The incision of the gluteal aneurysm and the ligature of the artery during direct compression of the internal iliac artery was first performed by me in 1895. The case is referred to in my work, "Etudes de Clinique Chirurgicale," p. 62 (O. Bertier, Paris, 1901). As regards the operation I said:—

> L'extirpation décidée, il fallait trouver un moyen préservant le malade de l'hémorragie qui suivrait fatalement l'ouverture du sac, surtout dans l'hypothèse de ligature profonde, celle-ci ne pouvant se faire peut-être, qu'en arrière de l'échancrure sciatique.
>
> Après quelques reflexions sur l'éventualité touchant la conduite à adopter pour éviter l'hémorragie, nous nous décidons pour la compression préliminaire directe de l'artère iliaque primitive. Nous pratiquons l'incision latérale en vue de la ligature de l'iliaque primitive, sous le chloroforme. Une fois l'artère découverte, nous la saisissons avec une longue pince hémostatique, dont nous avions eu soin de doubler les mors avec du caoutchouc. Cette pince est formée légèrement pour ne pas léser l'artère. Nous inclinons ensuite le malade vers le coté droit et nous commençons l'extirpation de l'anévrysme. Arrivé au terme de la dissection, et la ligature des vaisseaux ouverts achevée, nous retirons la pince de l'artère iliaque interne, puis nous nous assurons que l'hémostase est complète.
>
> Nous sommes arrivé sans encombre au terme de l'opération et sans que le malade ait eu à souffrir de pertes de sang considérables.

I am, Sirs, yours faithfully,
Dr. ANTONIO PACHECO MENDES

Bahia, Brazil. Professeur de la Faculté de Médecine de Bahia.

PARISH COUNCIL OF DURNESS, SUTHERLANDSHIRE.

To the Editors of THE LANCET.

SIRS,—This parish council in 1898 dismissed its then medical officer *without cause being given;* it has now continued its unjust treatment of its medical officers by dismissing its present medical officer. Might I warn the profession, as it is not likely that the next medical officer will get any better treatment? I shall be pleased to furnish any applicant with further information.

I am, Sirs, yours faithfully,
W. L MUIR,
Secretary, Scottish Poor-law Medical Officers' Association.

1, Seton-terrace, Dennistoun, Glasgow, Dec 9th, 1903.

A SUSPICIOUS STOP-GAP.

To the Editors of THE LANCET.

SIRS,—In experimenting on samples of coffee which I have found it desirable to cork down for variable periods, it has frequently occurred that a bad cork has started deterioration of specimens of my concentrated infusions and that while the "brew" of the same period, corked with a good cork, has remained sound a coincident specimen has "gone bad" apparently (and only) from a bad cork. It occurs to me that in a multitude of trades where corks are used there must be some effect produced on articles of merchandise and manufacture, not perhaps sufficient so to taint the particular article as to make it "bad" to the taste and yet quite enough to cause it to be deleterious. I merely throw the idea out as a bald suggestion: it may or may not be new; it may or may not be relevant. But it seems to me that where various articles of diet are accused of causing cancer (beer has been so "named") it would be just as well if we all contributed our suspicions, even though such suspicions may turn out to be ill-founded. Of course a really bad cork "corks" wine and a wise man rejects it, but in the specimens of coffee which have been spoilt in my investigations there has been no taste of cork. It is the tasteless deterioration which seems to call for some investigation.—I am, Sirs, yours faithfully,

GEORGE H. R. DABBS, M.D. Aberd.

Austin Friars, E.C., Dec. 5th, 1903.

THE LATE MR. W. J. WALSHAM: AN EXHIBITION OF SELF-CONTROL.

To the Editors of THE LANCET.

SIRS,—Sometime in the early eighties the late Mr. W. J. Walsham permitted me, a student at the time, to be present when he tied the right internal iliac artery in a patient at the Metropolitan Free Hospital. The hospital was at this period in a state of repair or removal and the operation was performed in what appeared to me to be the upper floor of a large warehouse used as a ward. Screens were placed round the scene of operation and the carbolic spray, then so fashionable, was mounted on a couple of boxes. The artery had just been exposed when one of the screens was overturned; it fell against the spray and in an instant there was a big blaze. The other patients began screaming and many of them started for the door. Mr. Walsham left his patient and assisted to put out the flames and quiet the inmates, and then he returned to his operation and separated and tied the artery without betraying the least disturbance.

I am, Sirs, yours faithfully,
A. C. F.

THE FEES AND EXPENSES OF PUBLIC VACCINATION IN RURAL DISTRICTS.

(FROM A CORRESPONDENT.)

THE attitude of the Government in regard to the Vaccination Act of 1898 is not reassuring; the failure to re-enact or to confirm for a term of years a measure which was avowedly tentative has been followed by a departmental inquiry by a committee appointed by the Local Government Board on the subject of the fees and expenses necessitated by the existing Act.

This inquiry has been forced upon the Local Government Board by the representations of certain boards of guardians. The guardians in various parts of the country have been alarmed by the sudden increase in vaccination expenses necessitated in some measure by the Act of 1898, but increased to a somewhat abnormal degree by accidental and unfortunate circumstances. I say "accidental circumstances" but the term is scarcely correct; the large outbreak of small pox in 1901–02 felt over a great area of the country and notably in London was the direct outcome of an increasing failure of compulsory vaccination, increasing since 1880 and finding its maximum in the four years preceding 1898. The amount of revaccination which has obtained in the last three years throughout the kingdom has been very great and a large proportion of this work has been thrown into the hands of the public vaccinators which ten years ago would never have found its way into those hands. It is this sudden increase of expense which has alarmed the boards of guardians and their attitude is easy to understand. It is not only the guardians (who are the administrators of the Vaccination Acts) but also their constituents, the ratepayers, who demand inquiry into the financial aspect of the existing method.

In the interests of the profession at large I have prepared the following summary of the work performed by the public vaccinators and the remuneration they receive and it must not be forgotten that they form a numerous and industrious section of the medical profession. Under the old Act (1876) the public vaccinator had to vaccinate or to revaccinate at his own house or at outlying "stations" at fees varying roughly from 1*s.* 6*d.* to 3*s.* per head; for this he had to collect his own lymph or to arrange for a good service of arm-to-arm vaccination. The work was never considered well paid; in fact, it never was well paid, and no Poor-law medical officer would in those days have accepted the post of public vaccinator if he had not practically been obliged to do so. Under the old Acts the public vaccinator in rural districts waited at home on certain days in each quarter, usually one day each three weeks at the beginning of each quarter, or journeyed to "stations" at a given hour in a corresponding manner and earned a fee for every child efficiently vaccinated; the vaccination of each child occupied at most five minutes; the inspection and the vaccination of each new batch took place at the same appointed interviews and the clerical work was confined to a short entry on each occasion in the vaccination register. There were no expenses for postage, dressings, or other material.

With this let the work now done under the provisions of the existing Act be compared. The mere clerical work takes longer than the whole operation of vaccination and inspection used to do. It is as follows. A list (Form H) is received weekly from the vaccination officer giving the names and addresses of children who have reached the age of four months but have not been vaccinated. A counterfoiled form has to be sent (with postage paid) to the parent stating that on such a day (within the hours of nine and four in the daytime) the public vaccinator will call to offer to vaccinate the child. On the appointed day the public vaccinator has to call and to offer to vaccinate The parents may refuse his services, the mother may be absent from home, or the case may have to be postponed. In these cases the public vaccinator receives no remuneration whatever for his journey, a journey which may involve a drive of over 20 miles made by appointment I know from a competent authority that in only about 2 per cent. of instances do parents ever take the trouble to write and so to save the public vaccinator this unpaid labour. From returns collected from public vaccinators it appears that an average of over 30 5 per cent. of the journeys undertaken are productive of no fee whatever owing to refusals and postponements. The operation of vaccination as performed under the orders of the Local Government Board is a very different matter from the routine of five years ago. The arm must be washed and rendered aseptic. All instruments must be sterilised before use, the lymph must be allowed to dry, and thereafter the arm must be dressed aseptically. The whole operation cannot now be performed under 20 minutes, whereas in former days 15 or 20 cases could easily be vaccinated in one hour. At the proper period the arm must be inspected and dressed at the child's home, and a supply of aseptic dressings provided for use until cicatrisation is complete. If the arm should require any subsequent attention this has to be rendered but no further fee is payable.

The distances travelled by public vaccinators in rural districts are very great. Many districts extend ten or 12 miles and cases have frequently to be seen eight or ten miles from the vaccinator's home. One public vaccinator who has investigated the point informs me that the proportion of long journeys to short ones is very high. In his case there have been 82 journeys of over four miles from home out of a total of 179 journeys of all distances in a period of three years. The relation is not accidental, it is found to occur in a large proportion of public vaccinators' experiences. This singular fact that the further from home he goes the more vaccinations the rural public vaccinator has to perform is usually to be accounted for by the competition of some neighbouring "one-spot" vaccinator, a private practitioner, the only serious competition which the public vaccinator meets among the really poor. On the other hand, the further from home the public vaccinator travels the less chance there is of making his visit useful for seeing other patients. The public vaccination visits therefore become visits *ad hoc*. The fees for this exacting work are determined between the boards of guardians and the public vaccinators. The latter sign a contract to perform the work at the specified fees, but this contract may be terminated by the board of guardians entirely at their own will and at 28 days' notice. The Orders of the Local Government Board (1898) have fixed a minimum fee thus: for every child born within the district who attains the age of four months without being vaccinated the public vaccinator receives 1*s.*; for each child successfully vaccinated 5*s*; and for each revaccination at the public vaccinator's own house or at an appointed station 2*s.* 6*d.* Boards of guardians are empowered to treat their public vaccinators fairly and to grant fees which cover the unremunerated work and the great distances which may have to be travelled In some cases 2*s.* or even 2*s.* 6*d.* is granted instead of 1*s.* for the registration fee.

When it is considered that every case which finds its way on to Form H involves a far larger amount of clerical work and a special visit in addition, the fee even of 2*s* 6*d.* compares very unfavourably with that paid under the Infectious Diseases Notification Act and equally unfairly when the fees are compared with those of the certifying surgeons appointed by the Home Office Many boards have refused to grant any advance on the minimum fee of 5*s.* irrespectively of the distances. In the union of Gillingham, Kent, the work performed, allowing for unpaid journeys, produces a remuneration of a little under 2*s.* per visit. In Ashby de-la-Zouch the estimate is at the rate of 1*s.* 10½*d* per visit. In the Devizes union the rate of payment is under 2*s.* per visit. In the union of Westbury on-Severn an attempt was made by the guardians to reduce the fees to the minimum of 5*s.* for all distances, the fees as contracted originally being 2*s.* 6*d.* and 7*s.* 6*d* for long distances. At the higher rate of payment the public vaccinator had travelled 1172 miles to vaccinate 745 cases for a remuneration of £45, being a fraction over 9*d.* per mile.

The amount of purely unremunerative work is in some instances enormous. The public vaccinator of Mere (Dorset) reports that in one year he travelled 40 miles to visit 17 houses without vaccinating a single case. From Ogley Hay (Lichfield) we obtain the report: "In 12 months I have made 1115 visits, 90 per cent. of which were over two miles from my house, and more than 50 per cent. of them from three to five miles. I estimate the remuneration at 2*s.* 9½*d.* per visit." It is a grave hardship that public vaccinators may only postpone cases for two months; many cases which have to be postponed cannot possibly be ready for vaccination in two months and the public vaccinator knows this, but the cases must be hunted up and revisited every two months by him or by the vaccination officer. Instances are reported from all sides in which postponement has been made five or six times with no payment for the labour.

When comparison is challenged, as it has been challenged, between the fees earned by public vaccinators and those charged for vaccination by private practitioners, sufficient regard has not been paid to the conditions and character of the work done or to the fact that the apparent fee per case earned by the public official has to recoup him (as far as it does recoup him) for an immense amount of work which earns no fee. The clerical and operative work involved in each case demands at least 35 minutes of time exclusive of travelling time and expenses, while dressings and a proportion of the postage have to be provided. In view of the distances traversed and the unpaid work performed no one could claim that 5*s.* for each completed vaccination is in any district a fair remuneration and any reduction of the existing fees will involve very grave hardship. Few, if any, boards give registration fees over 2*s.* 6*d.* and few give over 2*s.*, while the highest fees for the longest distances are about 12*s.* 6*d.* Even at these apparently high fees the average sum earned by each visit (when the unpaid visits are reckoned) is very small. In the union of Tiverton the fees are 5*s.* per case under one mile, 7*s.* 6*d.* under four miles, and 10*s.* 6*d.* over four miles, but the average per visit is, we are informed, only 2*s.* 2*d.* and the minimum fee is paid for registration (1*s.*).

Where minimum fees are paid the return for each visit is miserable; in one of the districts of Lutterworth the fee earned per visit is 1*s.* 9½*d.*, in Mansfield, 9½*d.*, in Gillingham, 2*s.*; in Devizes, under 2*s.*; in Gainsborough, though a fee of 10*s.* is given for long distances over six miles, the average earning per visit is said to be only 1*s.* These sums are ludicrously small when the distances and the time of actual work are properly estimated. I believe that in many instances in which the minimum fees have not been enforced the boards of guardians and the public vaccinators made an honest attempt to arrive at a fair remunerative wage, having consideration for the poor prevailing scale of fees for ordinary rural practice. But if this be so it is obvious that both contracting parties were quite ignorant of the mass of unpaid work which compliance with the requirements of the Act would involve. I am convinced that when the large mass of evidence which I understand has already been laid before the committee of the department is fully sifted and considered a sympathetic estimate of the value of the work performed will be taken.

Though there is no doubt that the public vaccinators are even now underpaid, there is equally no doubt that the Act of 1898 committed the public to an expenditure with which, in the absence of satisfactory explanation, it is not unnaturally dissatisfied. If the normal proportion of vaccination effected at the public expense had merely been maintained the increase in cost would have been viewed with concern by the ratepayers; but this proportion has been unexpectedly increased by two factors. An enormous increase in revaccination occurred all over the country during the years 1901–02; the accounts of public vaccinators which under the old Act stood at a usual average of about £10 per annum, and under the new Act would (for the birth-rate of the district) have stood at £25, suddenly shot up to £150 or £200, the figures in some areas reaching £2000 or £3000. In districts where no revaccinations at the public cost, except those of occasional telegraph messengers, had been effected for years, there were many hundreds performed in those two years. Further, many boards of guardians neglected entirely to establish public stations for revaccination, with the result that the vaccinators were sent for to vaccinate at the patients' own homes, by which the higher scale of fee was incurred by the authorities. It is within my knowledge that in certainly one rural district the public vaccinator, with the assistance of the local clergy, arranged stations within his area at which he vaccinated many hundreds of persons at the minimum fee of 2*s.* 6*d.* per head, whereas he might have received 6*s.* or 8*s.* per head if he had vaccinated them at their own homes. The people had the legal right to require his attendance at their homes, but fortunately for the local rates he improvised a more economical machinery of stational vaccination. The second factor which tended to increase the amount of public vaccination is the growing appreciation by the public of the methods of public vaccination and the recognised high quality of the lymph supplied by the Government establishment.

In the normal average working of primary vaccination the substitution of the domiciliary visit for stational attendance has induced a large proportion of mothers of the superior artisan and lower trading classes, who would have considered it derogatory to attend in company with a herd of poorer mothers at a public vaccination station, to avail themselves of public vaccination. This influence has been felt even more in the matter of revaccination. In the last two years large numbers of householders of superior position, even of considerable wealth, who would not have done so ten years ago, have availed themselves of the provisions of the Act to secure the services of the public vaccinator for themselves, their domestic servants, or their business employés.

The present Act provides an expensive and comfortable means of securing vaccination to everyone. The expense is undoubtedly considerable, but if it is deemed desirable on the part of the departmental committee now sitting to recommend means of retrenchment it is to be hoped that such retrenchment will not be at the expense of the public vaccinators in rural districts, who are already underpaid. Not only would a reduction in fees for the work performed be a hardship which the profession might resent, but it must be remembered that skilled public vaccinators—men of good professional status and trustworthy character—are invaluable apostles of vaccination for whose work it is worth the while of the State to pay adequately. A good public vaccinator, zealous to render his district a well vaccinated one, is an apostle of the value of vaccination whose service is worth to the State more than the bare statutory fees which he earns, and this fact has been in principle recognised by the Government in the long-established system of "grants" for vaccination, which are allotted to a great extent according to the excellence of vaccination in individual districts.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Housing Question.

BESIDES the Rowton House (now under construction) another experiment in the way of solving the housing problem by private enterprise and as a commercial matter is being made by a company under the title of "Homes (Limited)." The idea is to provide clean, sanitary, and cheap dwellings for the poor and the prospectus of the company pledges it to build flats suitable for those earning small wages and to take steps to insure their being occupied by tenants of that class. Two blocks of flats, four storeys high, have now been erected in the very poor district of Deritend. These buildings are divided into 60 tenements, 28 of which consist of one room each, to let at 3*s.* per week; 16 of two rooms each, at 4*s.* 3*d.*; and 16 of three rooms each, at 5*s.* The materials of which the flats are built have been very carefully chosen so as to make the walls and floors fire-proof, and as far as possible sound-proof and incapable of harbouring vermin. Each tenement has a private lavatory attached to it and there is a washhouse containing two boilers on each floor. Each tenement contains a ventilated food-cupboard and a sink with water laid on. The ends of all corridors are open for the purpose of insuring free ventilation and by means of a pulley placed in each it will be possible to haul up coal or heavy articles of furniture to any level. Gas-light is provided in the corridors and on the staircases, but each tenant will be able to use gas or oil in his tenement as he may choose. These buildings have been recently opened at a ceremony at which Mr. Councillor G. H. Kenrick, chairman of the company, presided and the Lord Mayor was present. The latter in the course of his speech said that he was grateful to the company for giving the city council a practical example as to whether it were possible for private enterprise to grapple successfully with one portion of the housing problem. The erection was in the nature of an experiment and he would much rather that such an experiment were made by private enterprise than by the municipality. Meantime it must be added that the council's policy with regard to the housing of the poor does not seem to meet with much support in a pamphlet issued by the Rev. Mr. Bass, a well-known worker amongst the very poor, whose parish, that of St. Laurence, comprises one of the poorest and most wretched parts of the city. With respect to the council project of opening up the courts he says: "The landlords are called upon to pay the cost of repairing properties; the front houses, taken down to make air spaces, are paid for by the corporation. The housing committee's estimate when applying to the corporation for their last grant was that the pulling down of such front houses would cost £100 per court. The experiment made in the condemned area is to be applied to the whole city. Now let us see what the cost will be. There are 6000 courts in Birmingham and, to state the case moderately, if only 1 in 4 is opened up it will cost the city £150,000. Not one single foot of land on which the houses stood will then be the property of the corporation, nor will they be the possessors of a single brick, whereas, on the other hand, £150,000 of municipal money spent in building houses at rentals of 3*s* 6*d.* to 5*s.* a week would go a long way towards solving the slum difficulty and leave a handsome estate in the hands of the corporation, which would be a positive source of revenue."

St. John Ambulance Association.

The annual meeting of this body has recently been held and the report then read stated that the year's working had resulted in a profit of over £18, leaving a surplus of about £85 after voting a sum of nearly £30 to the funds of the Birmingham corps of the St. John Ambulance Brigade. 19 classes were held during the period under review, of which 15 were male first-aid, three female first-aid, and one male nursing; five classes were held in connexion with manufactories. The committee was pleased to announce that the number of classes inaugurated by employers of labour continued to increase. In view of the success of the Birmingham corps it was desirable that a nursing division should be formed from among the ladies possessing first-aid and nursing certificates and the matter was now under consideration. It was stated that 29 medical men had given their services as lecturers gratuitously during the past year. The Lord Mayor, in his speech, alluded to the valuable services of the corps on various public occasions during the year and notably on the occasion of the great meeting at Bingley Hall addressed by Mr. Chamberlain.

Old Age Pensions.

A very remarkable light is thrown upon the proposals in this direction by certain statistics collected by the clerk to the West Bromwich Union in reply to a request from the Local Government Board which some time ago wrote asking for the information of the Select Committee, which had under [illegible] s' Bill of 1903, the number [illegible] 65 years of age who would [illegible] ouse with relatives having suitable accommodation for them if each had a pension of from 5*s.* to 7*s.* per week and also how many of them would wish to do so. The clerk pointed out that the persons included in this inquiry would not contain amongst their numbers those inmates who could not take care of themselves owing to some bodily or mental infirmity. From information which he had obtained he found that the number of persons over 65 years of age in the workhouse on August 5th was 325. The number who, in the opinion of the medical officer, could not satisfactorily take care of themselves owing to physical or mental infirmity was 203. That left 122 persons who might be described as candidates for the pensions. Of this number 22 had out-relief before they came into the workhouse, whilst in 98 cases no out-relief was given prior to their admission to the building. Further, out of the total cases 52 were admitted to the workhouse because they had been living under neglected conditions and 73 because of intemperance, whilst 82 were men and 40 were women. As the result of careful inquiries made it was ascertained that there was not a single person in the workhouse who was eligible for a pension under the conditions laid down. It was a matter for regret that during the inquiries that had been made only one case was found in which a man had been for any considerable time a subscriber to the funds of a friendly society, and that person had to seek the shelter of the workhouse because he had no relatives or friends with whom he could reside.

Vaccination in the District.

A good deal of discussion has taken place at recent meetings of the Dudley board of guardians with respect to the cost of vaccination and at the last meeting but one a report of the views of the Association of Poor-law Unions that the fee should be reduced from 5*s.* to 2*s.* 6*d.* and paid by the Treasury and not by the local authority was received with much approval. At the last meeting a statement of the cost of vaccination during the past years was made by the clerk. He stated that for the four years ending 1899 there were 7314 cases of vaccination and revaccination and the total cost was £1440, which averaged practically 4*s.* per case. For the last four years following the adoption of the order there were 9504 cases of vaccination and revaccination and the total cost was £4378, which gave an average cost of 9*s.* 3*d.* Of the 4*s.* the public vaccinators received 1*s.* 7¾*d.* and of the 9*s.* 3*d.* they got 8*s.* At a recent meeting of the Hanley town council statistics were given of the results of the North Staffordshire joint small-pox hospital. The chairman stated that the total number of patients admitted up to that date from the opening of the hospital was 259, of whom 125 were from Hanley. The total number of deaths in the hospital was 13. Of these deaths five patients were alcoholic subjects and death in their case was due to delirium tremens the result of excessive drinking. One patient died from heart disease and one from acute delirious mania. Seven deaths out of ten which occurred amongst the vaccinated patients were thus accounted for by causes other than small-pox. Of the total admissions into the hospital 31 were unvaccinated patients, with three deaths, being 9·7 per cent. Imperfectly vaccinated patients numbered 128. Of these ten died, seven of which deaths had been accounted for otherwise than by small-pox, leaving three who died from that disease, or 2·3 per cent. Well-marked vaccination was shown in 100 patients, amongst whom there were no deaths. There was no case of any patient being admitted to the hospital who had been revaccinated within the last seven years. Several patients had been revaccinated after being in contact with infected persons, but each case was of a mild character and there were no deaths.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh Medical Missionary Society.

IMPORTANT additions and alterations have just been made in connexion with the premises in the Cowgate of the Edinburgh Medical Missionary Society. The dispensary and students' residence at 39, Cowgate, known as the Livingstone Memorial Medical Mission, was erected by the society in 1877. At this institution young men and women are trained for medical mission work in foreign lands by similar training in the slums of Edinburgh. Since 1877 the work done at the Livingstone memorial has steadily increased. Last year no fewer than 9601 new patients were treated, including 3228 seen at the dispensary, 2413 visited at their own homes, and 2855 who required some slight surgical treatment. The work of the society abroad includes an institution at Agra for the training of native young men, a hospital at Damascus, and a mission station and dispensary at Nazareth. Since the society was instituted over 100 fully qualified medical missionaries have been trained and sent out. The extended premises in the Cowgate, which were formally opened on Dec. 4th by Lord Aberdeen, consist of a three-storey building with a frontage of about 160 feet ending on the west at the junction of the Cowgate with Candlemaker-row. The block to the east is the part formerly in use. It includes the Magdalene Chapel, an edifice which dates from the beginning of the sixteenth century and is traditionally associated with the first meetings of the general assembly of the Church of Scotland. The chapel entrance is on the left of the main corridor; to the right are two surgical rooms, while between those two rooms a corridor leads to a waiting room, two consulting rooms, and the dispensary. To the rear is a hall which has been enlarged by including in it what were formerly the consulting and waiting rooms and the dispensary. The hall is now large enough to accommodate between 200 and 300 persons. It contains a bust and crayon portrait of Dr. Livingstone and a stained-glass window, the funds towards providing the latter having been contributed by patients. On the first floor is the students' residence, including a bedroom for each student, a study between every two students, a dining hall, a library, and a missionary museum. All the rooms are to be heated by means of pipes. Formerly only six students could be accommodated, now there will be room for 12 men. During the first three years of their training the students live in Miller House, George-square, but during the fourth year they live in the Cowgate. Women students have a similar training but do not live at the dispensary. At present 18 men and four women are being trained under the auspices of the society. An important adjunct to the work of the society in the Cowgate is a temperance restaurant which occupies the western block of the building In connexion with this are a reading room, a billiard room, and a gymnasium, the object being to form a poor man's temperance club where he can be provided with good food and rational amusement at the lowest possible rates. The cost of the extension is estimated at over £5000.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Belfast Workhouse.

Dr. E. C. Bigger, medical inspector to the Irish Local Government Board, has just made a special report on the state of the Belfast workhouse which is one of the largest in Ireland. It stands upon 29½ acres of ground, employs 235 officials, and has during the winter an average of about 3400 inmates, made up of sick, aged and infirm, lunatics, children, and a few healthy adults. Taking the workhouse altogether there are 120 persons to the acre, but on the 11 acres on which the workhouse stands there are 200 persons to the acre, which is more than would be allowed in barracks, asylums, and similar modern institutions. Dr. Bigger asks whether the time has not arrived for the guardians to consider whether they should cease to erect any more buildings upon their present grounds. He suggests a kitchen for each ward or for each pair of wards. He praises the new nurses' home which has accommodation for 130 nurses and reports in eulogistic terms of the services of the visiting and resident medical officers and nursing staff.

Drumconrath Dispensary.

This dispensary, in Co. Louth, has been vacant over six months. The guardians have been unable to obtain a medical man, as the Irish Medical Association insisted on a minimum salary of £200 per annum. In the circumstances the Local Government Board proposed to amalgamate Drumconrath dispensary with two other districts and to make two medical officers do all the duty and to divide between them the salary formerly paid to the Drumconrath medical man. The guardians would not agree to this at first but on Dec. 8th they decided to leave the matter in the hands of the Local Government Board.

The late Dr. G. Gray, J.P., Newcastle, Co. Down.

Under the auspices of the Castlewellan Literary Society, of which Dr G. Gray, who practised for many years in that town, was first president, there was held in the court-house, Castlewellan, on Dec. 11th, a large public meeting, when the Countess of Annesley unveiled a portrait of the deceased practitioner. Lady Annesley, in referring to the high qualities of the late Dr. Gray, spoke in sympathetic terms of the self-denying sacrifices of the medical profession. Dr. Gray enjoyed the good-will, respect, and confidence of a large *clientele*, and it is pleasant to see—in a country like Ireland—people of all sects and every social position paying such a tribute to the memory of a deceased member of our profession.

Small-pox in Belfast.

On Dec. 14th four fresh cases of small-pox were notified to the authorities and the cases were promptly removed to Purdysburn isolation hospital. Each of the cases, as "contacts" with a case from Newcastle-on-Tyne, isolated some time since, had been under observation. The cases are a mother and two of her children and a young woman. Two "contacts" have been placed in the intercepting hospital.

The Poor-law (Irish) Commission.

This commission opened its sittings in the court house, Belfast, on Dec. 16th. The commissioners are Mr. W. L. Micks (chairman), Dr. E. C. Bigger, Mr. G. Murnaghan, M.P., and Mr. Mahon, LL.B., registrar. The inquiry is in reference to dissolution of unions, provision of auxiliary lunatic asylums, the better classification of the infirm, destitute, and sick, the boarding out of children, and the best method of dealing with casuals.

The Youghal Auxiliary Lunatic Asylum.

The board of governors of the Cork District Lunatic Asylum has built an auxiliary asylum at Youghal to which it proposes to remove harmless lunatics with a view to relieve the congestion of the parent institution At some recent meetings there was considerable discussion as to whether a visiting physician or a resident physician should be appointed at Youghal. At a meeting of the members of the Cork medical profession specially convened to consider the matter a motion was passed and duly forwarded to the governors urging them to appoint a resident physician, and mentioning amongst other reasons the fact that lunatics, owing to bolting their food, are liable to get choked, when medical assistance is required to be immediately at hand. At the following meeting of the board of governors this resolution was under consideration, when by a comparatively small majority it was decided to appoint a visiting physician. Amongst those voting with the majority was the Very Rev. Dr. Kelly, Bishop of Ross. Later, in reply to a communication addressed to him on a different subject, the bishop wrote to the gentleman acting as honorary secretary to the meeting of the medical profession and expressed the opinion that the action of the profession with regard to the asylum appointment was an unwarrantable interference and due to interested motives. At the meeting of the medical profession the reading of the bishop's letter naturally caused considerable indignation and a proposal was made that the resolution previously forwarded to the asylum board and the letter of the bishop should be jointly sent to the local press. However, it was pointed out that the adoption of that course would result in unpleasant discussions which could effect no good and it was finally decided that the members would best consult their own dignity by entering his lordship's letter on the minutes and marking it "read." A motion to that effect was accordingly unanimously adopted.

Possible Dangers of Saline Inj[illegible]

AT a meeting of the Hospitals Medical [illegible]der constr[illegible]ch was held on Dec. 4th three speakers drew [illegible]ing the [illegible]o some unfortunate results which had followed [illegible]ommercia[illegible]eous injections of saline solution. M. A. Bergé g[illegible]itle of [illegible]account of the first case It was that of an old man[illegible], sani[illegible]arterial and renal sclerosis as well as [illegible] two injections of saline sol[illegible] per 1000. After this he de[illegible] intense dyspnœa, a sense of [illegible] cyanosis, and on auscultati[illegible] Hallion and Carrion as well as Achard and [illegible] Laper had previously shown that intravenous injection of sa[illegible]line solution in an animal would bring about pulmonary œdem[illegible] M. Bergé's case is a clinical verification in man of th[illegible]is experiment. M. Achard and M. Paisseau in another paper [illegible] reported that they had made a post mortem examination on [illegible] the body of a woman who for secondary hæmorrhage after [illegible] hysterectomy had received subcutaneously within 24 hours [illegible] ten litres of artificial serum containing five parts of sod[illegible]ium chloride and ten parts of sodium sulphate per 1000. [illegible] Death was due to pulmonary œdema which was dem[illegible]onstrated at the necropsy and there were besides renal [illegible] lesions. It was not proved that these lesions were due s[illegible]olely to the sodium chloride being in excess, for the solut[illegible]ion of this salt was so weak as to have less than the norm[illegible]al osmotic power (*était hypotonique*). It was on account of this hypotonia that the muscles of the patient showed a smaller proportion of sodium chloride than did the muscles of a subject who had died from rapid suffocation, which were tested as a comparison. Nor can the sodium sulphate be held responsible for the death and M. Achard and M. Paisseau think that it was due to the quantity of water. Experiments on rabbits show that the animals die when either weak or strong solutions of sodium sulphate are injected. A rabbit injected with over a litre of the same solution as was employ[illegible] d[illegible]d within a few hours. Death was due [illegible] and the renal epithelium was affected [illegible]

"Dechloridation" and the "Dechloridated" Diet for Morbus Cordis.

At the meeting of the Hospitals Medical Society held on Nov. 13th M. Widal, together with M. Froin, M. Digne,

M. Vaquez, and M. Laubry, communicated the results of an inquiry which they had made into the above subject. The patients under observation were nine in number and all of them exhibited actual œdema or else signs of its recent occurrence. The first point to be noted was that a patient suffering from morbus cordis, even when just recovered from an attack of cardiac insufficiency (*asystolie*) with œdema, was not affected by the ingestion of chloride of sodium. Despite a progressive increase in the amount of chlorides given in the diet both the œdema and the weight diminished in three patients. Three others, however, showed an increase in weight under an additional dose of 10 grammes of chloride of sodium. A "dechloridated" diet—namely, bread, meat, potatoes, and butter all free from salt—given to four patients with morbus cordis either made no difference as regards weight or else diminished it very slightly, even after a test meal of salted diet. In fine, the action of a salt-free diet on cardiac œdema is rather to hold it in check than to cure it and does not cause the effused serum to disappear as it does in certain cases of Bright's disease.[1] M. Vaquez and M. Laubry gave it as their opinion that a diet rich in salts is generally dangerous for a patient with morbus cordis, whatever be the stage at which his complaint has arrived. As to a salt-free diet the indications for its use seem to be less marked than in cases of Bright's disease. During a period of acute but transient cardiac insufficiency a salt-free diet may with advantage be substituted for a milk diet. Continued for some little time after the attack has passed off it will prevent a relapse. In favourable cases a salt-free diet acts not so much as a cure but as a sustaining diet (*ration d'entretien*). It also has its uses in cases of chronic cardiac insufficiency with permanent œdema, for it is a pleasant change for the patient from a milk diet and it prevents a too rapid wasting.

Artistic Anatomy.

The anatomy classes at the Fine Arts School have a new professor who is at once a medical man and an artist. Professor Richer, the well-known sculptor, has for the past 20 years devoted himself to the search for truth in art, and the results of his first researches were published in a volume [illegible] "Artistic Anatomy" in 1890. At a later date he [illegible] the "Artistic Physiology of Movement in Man." [illegible] masterpieces of art were reproduced in this [illegible] and in the introduction, which dealt with [illegible] physiognomy, Professor Richer studied the relations existing between art and medicine. He has now inaugurated a new course of lectures at the Fine Arts School, showing by the history of art how the human figure has been represented and what were the means at the disposal of artists. Professor Richer deals with Egyptian art, with Greek art, with the influence on art of anatomical studies which began about the thirteenth century, and with the works of the primitive Italian artists. The course will also include lessons in practical anatomy the details of which will be drawn together with figure studies.

The Anatomical Evolution of Fractures which are moved with a View to bring about a False Joint.

At the meeting of the Academy of Medicine held on Dec. 8th M. Cornil gave an account of some experiments made in collaboration with M. Coudray upon the method of repair in fractures and showed various microscopical sections taken at different times during the period of healing. He said that in his opinion fractures which were not kept at rest had but little tendency to produce false joints and generally healed in the ordinary way. If, then, it is permissible to argue from the case of an animal to that of a man, fractures in the latter should not be kept at rest. M. Cornil's opinion goes to support that of M. Lucas Championnière who for the last 20 years has urged that fractures not kept strictly at rest heal twice as quickly as those which are so kept; moreover they are not followed by articular or muscular stiffness. M. Lucas Championnière considers that a fracture should not be immobilised unless there is some great deformity or tendency to deformity of the limb. In every other case gentle movements should be employed but in the case of young children movement should be very carefully used for fear of provoking an excessive amount of callus.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Measuring of Blood Pressure in the Right Atrium Cordis.

Professor Gustav Gärtner has brought forward a new and valuable method of clinical examination. It is a well-known fact that the veins of the skin of the dependent forearm look filled, and that they look empty during the elevation of the arm. This old clinical observation forms the starting point of an exact method of measuring of blood pressure in the right atrium cordis. If the dependent arm is slowly elevated and if the blood-vessels of the skin are observed during the process it will be seen that the collapse of the veins in the same person occurs always at the same moment, when the arm comes to a certain level. The turgidity of the veins diminishes gradually as the arm is elevated, until a time comes when the recently prominent walls of the vessels lie flat. In the healthy man this takes place when the forearm under observation is raised to the altitude of the insertion of the fifth, fourth, and third rib. The phenomenon depends upon the pressure in the right atrium cordis. The veins form untransparent manometer pipes, while it is possible to control the standing of blood in the vessels. Thus we have the possibility of measuring the blood pressure in the right atrium cordis.

Death from Electric Shock.

Jellinek's recent experimental researches show that various kinds of animals have different reactions against the influence of electric currents. Horses are killed by the electric current in street cables—i.e., a constant current of 460 volts—while unipolar application of constant current of 110 volts has a bad effect after a time. Small animals, such as rabbits, dogs, and guinea-pigs, are more resistant, while frogs and tortoises are not killed by currents of 10,000 volts. Death occurs through paralysis of the heart and respiration, and animals which recover show similar symptoms to those which occur in man after lightning stroke, such as paralysis, coming on after an interval sometimes, hæmorrhages, and ocular lesions. The injury to human subjects through electricity depends not only upon the tension and amount of the current, but, and in particular, upon the resistance to transmission, the duration of the shock, the direction of the current, and whether there was unipolar or bipolar application. The individual condition of the subject, his clothes and shoes, as well as the constitution of the soil on which he stands, must all be considered. Undamaged skin affords great protection against electric shock, which, of course, diminishes as the skin suffers from the application. Tensions of from 100 to 150 volts demand precaution, tensions of over 200 volts may be dangerous, and of 500 volts even deadly. There is a well-known case where a man was killed by a current of only 95 volts when standing barefoot in a mixture of potash and sugar and molasses, while in Vienna a man, though much damaged, was not killed by a current of 5500 volts, alternating current. The local symptoms caused by electricity are superficial burning, singed hairs, œdematous infiltrations of tissues, or actually ragged wounds, together with injury to the special senses through the eyes and ears. Very interesting observations made by Jellinek show that sometimes tissue which looks at first unhurt, although in the neighbourhood of burnt spots, will later necrose, the injury spreading to the deeper lying tissues, the prognosis in such cases being very bad. Post mortem Jellinek found many small blood extravasations in the grey substance of the brain and the cord.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Patent Medicines and Articles of Adoration.

Dr. S. A. Knopf, a well-known authority on tuberculosis, in a pamphlet recently issued by the committee on the prevention of tuberculosis of the Charity Organisation Society of New York, describes many methods whereby the danger of spreading contagion by consumption may be lessened. The writer severely criticises the adoration of certain articles and the endorsement of patent medicines. He writes as follows: "It might be of advantage if such articles of adoration as crosses, statues, or, as in Greek churches, pictures, which are often kissed by devout worshippers, were included in the periodic disinfection. Kissing the Bible when taking an oath should be discouraged by jurists and divines." Referring to the endorsement of patent medicines Dr. Knopf says: "Ministers of all denominations should consider it beneath their dignity to allow their names to be used to advertise patent medicines and other secret remedies. I am convinced if they were aware of the fact that many of the advertised patent remedies contain as much as 30 or 40 per cent. of alcohol and often more dangerous ingredients they would refrain from endorsing the use of medicines of whose composition they have not the least idea. Neither should religious newspapers lend their columns to the advertisements of nostrums and patent remedies of all sorts. It is to be regretted that patent medicines are also not unfrequently recommended by statesmen and legislators. Their personal endorsement of this or that secret remedy, given without forethought and perhaps even with good intentions, has often done irreparable harm to the sufferers." The wholesale endorsement of patent medicines by men and women in good positions is a crying evil on this side and it is to be hoped that Dr. Knopf's plain speaking may do some good. The chief sinners in this respect are clergymen who, not content with advising as to a person's spiritual affairs, too often take upon themselves the rôles of physicians. It would appear from a perusal of accounts which are to be read now and again in THE LANCET that British clergymen are somewhat addicted to prescribing for the bodily ills of their flock and to recommending patent medicines, although not to the extent that prevails here. There is little doubt that clergymen give medical advice and endorse patent medicines with the best intentions in the world, but good intentions unless accompanied by knowledge usually bring about bad and unexpected results. The bodily care of the individual is therefore best left to those who have made a study of that matter and the public should be warned against accepting the advice of well-meaning but irresponsible persons.

---

[1] THE LANCET, July 4th, p. 61.

Two Motor-men for Electric Trains.

The *New York Medical News* in its issue of Nov. 28th strongly urges that two men should be placed in charge of all electric trains. The *Medical News* article says in part: "Many things may happen unexpectedly to a man that will render his position of motor-man likely to be a source of danger to those whose lives are dependent in all emergencies on his good mental and physical condition. During the ordinary hours of the day usually at least one of the other train-men is in a position to note any presages there may be of impending danger. During the rush hours, however, the crowd makes this absolutely impossible and passengers themselves are too uncomfortable, as a rule, to take any precautions looking to their safety." It is pointed out that a motor-man may be suddenly attacked by disease or may be suffering from the incipient stage of some severe internal ailment, such as pneumonia or an acute attack of nephritis, and may easily over-estimate his strength in his desire to put in a full day's work. Accidents, and serious ones, have happened on account of the physical incapacity of the motor-man An occurrence of this nature took place in the vicinity of New York recently. The warning of the *New York Medical News* is timely for London, seeing that the metropolis will soon have many miles of railroad on which the cars will run by electricity. There can be no doubt that accidents would be avoided by adopting the plan suggested by the *Medical News*. Furthermore, a pleasant sense of security would be afforded to the general public who have learned by the unfortunate experiences of the past few years somewhat to distrust electricity as a motive power, or rather to regard with a lively sense of apprehension the possible catastrophes resulting from its use.

Small-pox in New York State.

The Health Department of New York State has recently reported that small-pox prevails extensively throughout the State. The disease is especially serious in Chautauqua and Cattaraugus counties. The situation in regard to small-pox is also reported as bad at Medina, Orleans county, where there have been 92 cases in two months. The Health Department has stated that health officers are generally doing their utmost to quell the epidemic but receive indifferent support or actual opposition from local boards and citizens in the enforcement of vaccination and quarantine. Weekly bulletins will henceforth be issued by the department until the situation is materially improved, naming the places where small-pox exists, and other steps will be taken towards the enforcement of vaccination and quarantine.

Dec. 7th.

Obituary.

WILLIAM NEWMAN, M.D. LOND., F R C S. ENG.

DR. WILLIAM NEWMAN of Stamford, who died at that town on Dec. 3rd, aged 70 years, was one who in a prominent way upheld the dignity and advanced the honour of his profession. He was born on August 29th, 1833, at Hallfield, near Sheffield, and was the son of Mr. Robert Newman, land agent to Earl Fitzwilliam. He was educated under Dr. Jacob at Sheffield Collegiate School, where he was well grounded in the classics, and even as a boy was practised in the art of public or semi-public speaking. He was a nephew of the late Dr. Freeman Eaton of Ancaster, and began the study of medicine in the house of his uncle, during which time he acquired the friendship of a young nobleman who is now the Earl of Ancaster. He received his medical training at St. Bartholomew's Hospital where he made the friendship of Sir James Paget, Sir Thomas Smith, and the late Dr. James Andrew, besides having a distinguished career. He took the degree of M.D. at the University of London as well as the Fellowship of the Royal College of Surgeons of England, and had he chosen he could have been appointed assistant physician on the staff of St. Bartholomew's Hospital. For a short time he practised at Fulbeck near Grantham, but in 1863 he went to Stamford where he was appointed surgeon at the Stamford and Rutland Infirmary and held the office for 30 years. He then retired and was made consulting surgeon, but in a few years resumed the surgeoncy and began to operate in the infirmary again, and continued to do so until this autumn.

A personal friend sends us the following estimate of Dr. Newman's character: "Newman was a man who never wasted time and he got through a large amount both of work and recreation. He had numerous interests. He was an antiquary, a good draughtsman, an excellent shot; he rode the tricycle, loved animals, and took great delight in gardening. Himself a great reader and lover of books, he took much interest in education and was a very valuable member of the educational authority at Stamford. Although a magistrate he seldom sat on the bench. He was a good photographer and had an excellent installation for producing the x rays and the high-frequency current. He collected coins. But these are comparatively minor matters The salient features of Dr. Newman were his eminence as an all-round practical medical man, as an excellent physician, and as an accomplished surgeon. Not less worthy of note were his high character, his devotion to duty, his never-failing self-respect, and rectitude of conduct. His manner did not belie him. He was full of dignity and courtesy and he was remarkable for the care and precision which he carried into all his actions great and small. He was devoted to surgery and enjoyed above all things talking over its problems with a congenial spirit. He scorned humbug and never pretended to know more about a case than he really did. He would spare neither time nor money to get to the bottom of a difficult case. Being reserved and rather austere in manner to strangers, he was not the man to be universally appreciated by the silly and by the superficial At heart he was of a kindly and lovable nature."

For many years Dr. Newman's position in Stamford and the neighbourhood was that of a medical man trusted and admired, a friend loved and respected by rich and poor, great and small, and especially trusted and respected by his professional brethren who constantly called him into consultation. Never did any practitioner do more by his own personal conduct and character to raise the position of the medical profession in his own district than did Dr. Newman, and that steadily and consistently for 40 years. His life-long friend Sir James Paget, who had many points in common with him, said of him that such men as Newman made the profession. He was the author of

"Surgical Cases," "Drainage and Water Supply of Towns," and of various contributions to the journals Being President of the *Lincolnshire* Medical Benevolent Society which this year celebrated its centenary, he compiled the interesting pamphlet of records of that society, which was recently reviewed in THE LANCET In his last illness he was faithfully and devotedly attended by his friend and colleague Mr T P Greenwood and was visited several times by Dr C O Hawthorne He had been losing weight seriously for some months Finally he was attacked with pleurisy and serous effusion on the right side Although relieved several times by paracentesis he gradually sank His heart had not been strong for some years and he had consequently gone to live at the upland village of Luffenham, in a delightful cottage, partly built by himself, with a lovely garden which owed most of its charms to the skill of Mrs Newman For the opportunity of retiring to this particularly healthy village he thanked Lord Ancaster He had married a second time in 1876 Miss Charlotte Cumming of Hall Place By his first wife, Miss Sarah Tinley Newton, daughter of Mr William Newton of Sudbrooke, Lincolnshire, he left two sons and four daughters, by his second wife one son One of his sons is Captain E A R Newman of the Indian Medical Service

SAMUEL WOODCOCK, M D BRUX, L R C P, L R C S EDIN AND L M, L S A LOND

THE death of Dr Woodcock took place on Dec 12th at Manchester He was well known in medico political circles and was at one time a candidate for a seat upon the General Medical Council as a Direct Representative

The following appreciation of him has been sent by our Manchester correspondent —The death of Dr Sam Woodcock removes from our midst one of the most energetic and active minded workers in various fields that the medical profession in Manchester has ever had cause to mourn He died at his house in Stretford road on Dec 12th at the comparatively early age of 63 years He was born near Glossop in 1840 After leaving school he was apprenticed for five years to a medical man at Middleton and after passing through this stage he became for a time an assistant to the house surgeon of the Chorlton Dispensary, so that he had considerable familiarity with routine medical work before going to Glasgow as a student In 1866 he passed as L R C P, L R C S Edin and L M and also obtained the L S A qualification In 1877 he took the M D degree of Brussels His first appointment was that of one of the medical officers at the Withington workhouse, which he held with credit to himself and with the confidence of the board, of his colleagues, and of the inmates until he gave it up to begin practice in Hulme, where he soon became one of the most popular practitioners He held the appointments of district medical officer and public vaccinator for a part of the Hulme district of the Chorlton union and also that of certifying factory surgeon, and won the respect and the affectionate regard of his patients in that populous district by his professional skill and genial kindly disposition But he was known in Manchester almost as much for his political as for his medical activity Though from his infancy he was surrounded by a Liberal environment and from his youth up was a keen and ardent politician, his kindly temper and sense of humour saved him from the bitterness which sometimes accompanies devotion to politics He was a popular speaker, was fluent and racy, and had at command an abundant supply of humour After the retire

essed to

esented

private

reasons For many years he was a very familiar figure at the Reform Club in Manchester, was chairman of the political committee and had also been president and vice president. In 1891 he became a member of the School Board and took an active part in its proceedings until 1900 In 1892 he was elected a member of the Stretford local board and about the same time was made a magistrate for the city of Manchester At the city police court this week Mr Bri rley, the stipendiary, said that they could not begin business without expressing their sincere sorrow at the death of Dr Woodcock and recording how serious a loss they had sustained, and testimony has been borne by others to his conduct on the bench to his painstaking discrimination, and to the kindness which he showed towards those who were brought before him Notwithstanding the fact that his political and social activities seemed almost to overshadow his medical life Dr Woodcock was a hard-working practitioner and took much interest in the various local medical societies He was an original member of the Clinical Society of Manchester and had been president and vice president He had also held the position of president of the Lancashire and Cheshire Branch of the British Medical Association, and entered earnestly into the questions of medical politics which so greatly interest a large proportion of the members of the Association It need scarcely be said that he took the Liberal view in almost all cases, enforcing it with considerable power and with evident sincerity It should be mentioned that he was a man of strong religious feelings and although a conscientious Nonconformist he was no bigot and worked amicably with those who differed from him in opinion on the School Board and elsewhere Very many will endorse the words of the *Manchester Guardian* "In private life Dr Woodcock's genial disposition and admirable social qualities made him popular with a very large circle of friends"

Medical News.

UNIVERSITY OF CAMBRIDGE —The following medical and surgical degrees were conferred on Dec 10th —

—R T Worthington,

I Pinches Sidney

nith and H H Weir,

Dr D MacAlister, Dr J H Drysdale, and Mr T Strangeways Pigg have been appointed additional examiners for Part I and Mr D Arcy Power and Mr C W Mansell Moullin additional examiners for Part II of the third M B examination

PRESENTATIONS TO MEDICAL PRACTITIONERS —Mr. W S Wade, L R C P Edin, L F P S Glasg who has acted as surgeon to the Wakefield city police for 38 years, was on Nov 26th presented by the chief constable, on behalf of the members of the city police force, with a silk umbrella as a mark of esteem Mr Wade then presented the force with a large framed photograph of himself —On Nov 27th Mr I Hitchins J P, on behalf of the members of the St Agnes (Cornwall) Miners' and Mechanics' Institute, presented Mr William Whitworth, M R C S Eng, L S A., with a framed portrait of himself as a mark of respect and in recognition of his services as honorary secretary of the institute for 21 consecutive years —On Nov 30th Mr Thomas Johnstone, M D, was entertained at a dinner by a number of friends and patients and presented with a silver salver and rose bowl the total weight of which amounted to about 150 ounces The salver bore the following inscription 'Presented to Thos Johnstone Esq M D Edin, M R C P London, by grateful friends and patients on his retirement after nearly 30 years of general practice at Ilkley Nov 30th, 1903' The dinner and presentation took place at the Middleton Hotel, Ilkley

THE CHARGE AGAINST A HERBALIST COMMITTAL FOR TRIAL —At Southwark on Dec 10th, before Mr Paul Taylor, the hearing was concluded of the charge against Jethro Lardent, aged 38 years, herbalist, of Southwark Park road, and Ada Booth aged 34 years, *alias* Lardent, of being concerned together in performing illegal operations upon Miss Rebecca Mitchell Mr Bodkin prosecuted for the Treasury Miss Mitchell, who appeared to be very ill, now gave her evidence in detail She was to pay the prisoners £10 and actually paid £8 She underwent several operations because none were successful Since the prisoners had been in custody she had given birth to a child but it had not lived Dr A P Luff said that certain instruments found in Lardent's shop, one of which was blood stained, could have been used in the commission of the offence of which the prisoners were charged. He had examined 16 pills which, it had been alleged were given by Lardent to Miss Mitchell. Ten of them were composed of aloes capsicum, and sulphate of iron, and the remainder consisted of oil of pennyroyal, ginger, and other vegetable substances. —Lardent I absolutely deny that there was any pennyroyal improve it. We know the disastrous effect of the approval of semi-public bodies to any method in the past

If the society adds a note to the method which it formulates somewhat to the following effect, it might be the means of not crushing out attempts to improve: "Note.—The above method is the best that has been brought to the notice of the Royal Medical and Chirurgical Society up to the present time (here *give* date), but the society will always be ready to consider any suggestion for its improvement or for another method." I am, Sirs, yours faithfully,

Dec. 14th, 1903. A. B. C.

BRITISH MEDICAL BENEVOLENT FUND.

THE treasurer (Dr. Samuel West, 15, Wimpole-street, W.) has the pleasure to acknowledge the receipt of the following further donations in response to Sir William Broadbent's appeal:—"A Friend," per R. D. P., £31 10*s.*; Mr. W. A. Satchell, £11 7*s.*; and Mr. E. W. Thurston, £1 1*s.*

THE DETERMINATION OF SEX.

A SERIES of experiments on the determination of the sex of the fœtus has been made by Dr. A. Ambrose and the results are given in a paper which he has forwarded to us but which is too long for insertion in the present crowded state of our columns. At the outset he expresses a certain amount of approval of the theories of Dusing who holds that the determination of sex is influenced, if not controlled, by the relative degree of generative force in the parents. Guided by this principle, Dr. Ambrose devised a method by which he was able "to alter the generative force of the parents," but unfortunately he leaves us totally in the dark as to the details of the method employed. After pointing out that animals which bring forth more than one at a birth are of little use in such inquiries, he continues as follows:—

> The number of experiments is so small that of course no general deduction can be drawn from them, yet they seem to point in so definite a direction that they are worth recording if only to encourage others in the same way, and extending, as they do, over a period of five years any chance element of season or time may be eliminated. It appeared that the way to go to work was to alter the generative force of the parents, and this could be done either by elevating the male and depressing the female or *vice versâ*. In the cases of cattle and horses convenience indicated the treatment of the female; in that of human beings both sexes respond to treatment.
>
> 1. In all over a period of five years 32 cows were treated, 17 with a view to their production of male offspring and 15 for female. Of these, 15 of the 17 had bull calves and two had female calves; of the 15 treated for female offspring all had female calves.
>
> 2. In the same period 10 mares were treated, five for each sex. Of these, the five treated for males all had males and of the five treated for females four had fillies and one a male.
>
> 3. These experiments were so far satisfactory that it was determined to extend the investigation to the human species, and 30 married couples were treated. Of these, there were 20 who desired boys and 18 had them, while ten wished for girls and nine were born to them.

IMPROPER ADVERTISEMENT.

A CORRESPONDENT informs us that he has seen in the windows of a new house in the south-eastern district of London placards to the effect that

Dr. —— will shortly occupy this house.

He asks us our opinion on the publicity that is thus given to Dr. ——'s residential intentions. In this kind of matter medical men must to a certain extent be a law to themselves. The General Medical Council has more important functions to discharge than to discriminate between the *affiche* which is legitimate and that which is illegitimate. Our correspondent asks us to give our opinion in this particular case, and we think that good taste has been transgressed. It can only matter to Dr. ——'s patients where he lives and he should have been able to notify them of his change of address in the ordinary manner.

A GRIEVANCE OF THE CIVIL SURGEONS WHO SERVED IN SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS,—Will you allow me to protest against the action of those in authority in exacting £1 (instead of 5*s.*), and causing much trouble and inconvenience (not to say loss), from civil surgeons who risked their lives and gave their services for their country by doing at least 12 months' hard military duty in South Africa, because these civil surgeons were not able or forgot to notify their change of address to P.M.O. Army. This seems a punishment that is hardly merited.

I am, Sirs, yours faithfully,

Dec. 8th, 1903. FOUR CLASPS.

THE SHAFTESBURY INDUSTRIAL BETTERMENT LECTURES.

IN THE LANCET of Nov. 28th (p. 1513), in a leading article dealing with the work of the Mansion House Council on the Dwellings of the Poor, a sentence occurs attributing the Shaftesbury lectures to the council. Mr. G. F. Warden, the organising secretary of the Shaftesbury Industrial Betterment Lectures, has written to us stating that this is a mistake and that the Shaftesbury lectures are quite another and distinct organisation. Our information was derived from the report of the council for the year ending June, 1903, which we have consulted again since receiving Mr. Warden's letter. At the bottom of p. 12 of the report is a paragraph which certainly bears the construction that we put upon it, but which, read in the light of Mr. Warden's letter, assumes another signification. Mr. Warden also demurs to a statement in our leading article that the Mansion House Council on the Dwellings of the Poor was responsible for the meeting of members of Parliament on the housing question last July. On p. 9 of the same report of the council it seems to us that a definite claim is made by the council to have performed the work which we attributed to it. We regret to have accidentally belittled the work of the Shaftesbury Industrial Betterment Lectures with the organisation of which we were not familiar.

THE THRIFT OF THE SALVATION ARMY.

To the Editors of THE LANCET.

SIRS,—I was requested to examine two candidates for service in the Salvation Army and to make a report. For this I was offered the fee of 2*s* for each subject and I was told that a medical man had accepted 1*s.* for the same service. The following is a *résumé* of the form which I had to fill up:—*Family history:* Father, mother, brothers, sisters, living or dead? State of their health and cause of their death? *Present state:* State of ears, eyes, throat, tonsils, and teeth, with number of extractions. Examine and report on heart sounds. Examine chest (shape, capacity, expansion, and sounds as ascertained by percussion and auscultation). Examine chest for disposition to tubercle. Has the patient suffered from fits, rupture, piles, rheumatism, varicose veins, small-pox, and skin diseases? What operations have been performed, what bodily defects are present? In females note uterine functions and walking capacity. To these general remarks were to be added.

I wrote to the adjutant major of the Salvation Army stating that the fees proffered for these minute and searching examinations were inadequate but I have had no reply. I inclose the letter brought by one of the applicants to me. I should like to know if any other medical men have had these forms and if they have accepted such fees.

I am, Sirs, yours truly,

Dec. 9th, 1903. GRIFFIN WILKES, M.R.C.S., L.R.C.P., L.S.A.

[INCLOSURE.]

The Salvation Army,
National Headquarters, 101, Queen Victoria-street,
London, E.C., Nov. 9th, 1903.

DEAR SIR,—This letter will be handed to you by an Applicant for service in the Salvation Army. As a large number of such Applicants, who have been duly passed by Medical Men, have had to return to their homes, after a short trial, as physically unfit, it would be of considerable assistance to us if, in filling up the inclosed Certificate, you would kindly give special attention to the following points:—

The work of the Salvation Army is hard. It differs very much from the ordinary routine of regular Pastors, Lay Evangelists, or Bible Women, and makes heavy demands upon the whole nervous system as well as upon particular organs. Meetings are held every day. Speaking and Singing is constant. Any weakness of the lungs, throat, or heart is especially likely to develop difficulty. Functional irregularities in Female Applicants are of serious importance, and when the menstrual flow is excessive and prolonged, or when it occurs too often, it is desirable that this should be especially mentioned.

Nevertheless, it frequently happens that strong and wiry constitutions stand the work well, even though there be weakness in particular directions. On the other hand, you will place us under obligation if you will kindly point out Applicants who are generally weak, though you may be unable to detect any actual organic disease or deficiency. Women who are unfit to walk reasonable distances should be especially named to us.

You are, of course, aware that open air work, exercise, and regular habits (such as are required from our Officers) are extremely useful to young people, especially to those who may now be working under unfavourable conditions, e.g., in the unhealthy atmosphere of Factories, &c., so that in some cases of present weakness the change to our service would, no doubt, be permanently beneficial. We are most anxious to avoid throwing burdens on any who are not physically strong enough to carry them, and I thus venture to trouble you with these particulars.

I am, dear Sir, yours faithfully,

THOS. B. COOMBS.

*** Mr. Coombs makes out an excellent reason for the close medical examination of candidates for enrolment in the ranks of the Salvation Army but we see no reason why medical men should not be paid for helping the Salvation Army in the selection of recruits.—ED. L.

WE have received a manuscript entitled "Diphtheria: Some Statistics and a Point of Treatment," which bears neither the name nor the address of the author.

◆

Medical Man writes to us inclosing a pamphlet which he says was distributed to young and old at a football match held recently in the south of London, and asks us to judge whether it is a fit and proper publication for the hands of the laity. The pamphlet is an obscene publication termed "Vitality," and is

published by the Health Culture Publishing Company of 22, Budge-row, Cannon-street, London, E.C. Is this a trade name adopted by a person called Jonathan Nicholson, who used to conduct "The Magnetic Nerve Invigorator Company" of the same address, and on whose methods we have had occasion already to comment unfavourably (THE LANCET, Nov. 8th, 1902, p. 1297)? The advertisements in "Vitality" include the business cards of so-called "physical culture" specialists, the claims to attention of proprietors of bath cabinets, and magnetic (?) apparatuses. The advertisements also re [illegible]
weakness, a douche [illegible]
treatises, the literary [illegible]
magnetic outfits" (for nervous and sexual ailments). The contents of the magazine are in keeping with the advertisements. Articles on physical culture, written apparently to puff the wares advertised, are stuffed full of preposterous and indecent nonsense. There is no difficulty in guessing our reply to our correspondent's question. The paper is not fit.

Surgeon.—We have been unable to find the name of the makers of the preparation in question. We have seen it advertised in American journals as an analgesic and antipyretic.

Practitioner, in our opinion, is at liberty, if he thinks it advisable, so to style himself on his door plate.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

An Address

ON

THE DIAGNOSIS AND MANAGEMENT OF DOUBTFUL CASES OF DIPHTHERIA.

Delivered before the Medical Officers of Schools Association on Nov. 26th, 1903,

BY F. FOORD CAIGER, M.D., F.R.C.P. LOND.,
MEDICAL SUPERINTENDENT OF THE SOUTH-WESTERN FEVER HOSPITAL, STOCKWELL.

MR. PRESIDENT AND GENTLEMEN,—Apart from its purely scientific aspect the diagnosis of any infective illness possesses a special interest for the practitioner of medicine in view of the various measures of a preventive character which he may feel called upon to adopt. And to the members of this society who, in virtue of their office, are held responsible for the health of our large schools, each of which may be regarded as an aggregation of particularly susceptible subjects, the remark applies with special force. The medical officer to a large public school is so frequently called upon to decide as to the nature of doubtful cases of infectious illness, and the issues dependent upon his decision are in some instances so important, that he must necessarily have devoted a good deal of anxious thought and critical consideration to the elucidation of such questions. Fully realising this, I feel no small diffidence in addressing a society, most of the members of which, by reason of their special knowledge and experience, apart from their high scientific attainments, must rightly be regarded as experts, and I take this opportunity of expressing my appreciation of the honour you have done me in asking me to open this discussion. For the purpose of discussing the subject with which we are concerned this afternoon—viz., the diagnosis and management of doubtful cases of diphtheria—I would first direct your attention to the all-important question of diagnosis and afterwards to the consideration of the measures of a preventive character which have for their object the limitation of the spread of infection.

A well-developed attack of diphtheria in which definite membranous exudation is visible on the fauces is not likely either to escape recognition or to be mistaken for anything else. It is quite otherwise, however, in respect to those sore throats in which no exudation at all can be detected or at most a little cheesy deposit on the site of the follicular crypts, or perhaps one or more small necrotic-looking areas on the surface of the tonsils. The real nature of such cases is often very difficult to determine on clinical evidence alone. The same thing is true in respect to purely nasal diphtheria, which is very likely to escape detection altogether, especially when, as is usually the case, the patient presents but little if any indication of illness. It is to the purely nasal cases that I am referring Instances in which the nasal cavities are involved, either by extension, or concurrently with the fauces, are, as is well known, characterised by more than average severity. These nasal cases are a distinct source of danger to the community by reason of the insidious character of the affection and in many cases their existence has only been revealed after the lapse of a considerable period of time by their having infected other persons with severe and even fatal diphtheria. The havoc which may result from the presence of a single unrecognised case of nasal diphtheria in a school, institution, or ward in a children's hospital may be easily imagined and need hardly be seen to be appreciated, and in any investigation into the source of an apparently sporadic outbreak of diphtheria the importance of carefully examining the condition of the nasal cavities of those who have been in contact with the sick cannot well be over-estimated.

Although a considerable amount of assistance in the diagnosis of doubtful cases of diphtheria is usually to be derived from a careful consideration of the clinical appearances it is hardly going too far to say that at the present day the nature of a doubtful attack is practically determined by the result of bacteriological examination. Now without intending for a moment to minimise the immense importance of bacteriological examination in the hands of an expert observer, it cannot be denied that the insufficiency of our present knowledge on certain important points connected with the bacteriology of diphtheria, apart from a fallacy which is inseparable from the method itself, materially detracts from the complete reliability of the bacteriological test. I refer more particularly to the difficulty which is frequently experienced in the identification of the bacillus, owing to our uncertainty as to the limits of intranormal variation, both in respect to its form and virulence. The fact has long been recognised that in diphtheritic as in doubtful and even healthy throats bacilli are not infrequently found which more or less closely resemble the diphtheria bacillus but which are innocuous when injected into animals. It has been customary to refer to such organisms collectively as "pseudo-diphtheria" bacilli, without regard to certain important differences which are now recognised as existing between them. The term has proved an unfortunate one as tending to cause confusion and its use should certainly be restricted. Indeed, it would be better that the term "pseudo-diphtheria" were dropped altogether. The organism which has been most frequently referred to under this name is the Hofmann bacillus, of which the special characters are now pretty generally known. It was originally described by Löffler in 1887 as not infrequently present in diphtheritic throats and though for this reason it was frequently associated with the true bacillus which it closely resembled Löffler found it invariably innocuous to animals. In the following year Hofmann further extended the inquiry and showed that the bacillus was even more often present in sore throats which were not diphtheritic, and indeed that it could by no means infrequently be recovered from the throats of perfectly healthy persons. He, like Löffler, found the bacillus devoid of virulence and came to regard it as of a distinct species. This important observation of Hofmann, that the bacillus which bears his name is often present in normal throats, has been amply confirmed by a number of subsequent observers, notably by Roux and Yersin in France, and in this country by Cobbett and Graham-Smith in the course of certain admirably conducted investigations into outbreaks of diphtheria which occurred within recent years in Cambridge and Colchester respectively.

The [illegible] whether, under favourable conditi[illegible] is capable of developing into a [illegible]s been a fruitful source of experiment and discussion amongst bacteriologists for years. With but few exceptions observers have confessed their inability to effect this conversion by artificial means. Richmond and Salter, it is true, claim to have succeeded by passing the organism through several generations of finches; Hewlett and Knight state that they were eventually successful in imparting virulence to what appeared to be a typical Hofmann bacillus by carrying it through a number of generations on different culture media, but in neither case were the experiments altogether convincing. More recently, too, Lesieur claims to have brought about this result in three different ways: (1) by the introduction of the bacillus inclosed in collodion capsules into the peritoneum of rabbits; (2) by long-continued cultivation in peptone broth (in one case eight months being required); and (3) by simultaneous inoculation of the staphylococcus aureus. But the data on which Lesieur's claim is founded are wanting in completeness. If such transition be capable of taking place, however gradually, in the human subject our views on the etiology of diphtheria, having regard to the frequent presence of the Hofman bacillus in the normal throat, will have to be materially extended and our measures of prevention reconsidered. So far, however, whatever be the real possibilities in the laboratory, no evidence has been adduced that this ever does take place in nature and the balance of opinion is opposed to the Hofmann bacillus as a potential source of diphtheria.

Now the Hofmann bacillus, although, as I have stated, it is occasionally present in diphtheritic throats in association with the true bacillus, is readily distinguishable from the Klebs-Löffler organism by certain morphological, cultural, and biological features which are now well recognised. It would therefore seem permissible to speak of it as a "pseudo-bacillus"—if it be necessary to retain the term—and to assume that it is specifically distinct. In respect, however, to certain other bacilli which are frequently present in the throats or nasal passages of those who, without showing any obvious affection themselves, have been in close contact with the disease the relation is by no means equally clear. I refer to those bacilli which are also commonly classed as "pseudo-diphtheritic," which, though quite indistinguishable from the true bacillus in their morphology, staining, and cultural reactions—especially the power of producing acid in glucose broth—are found to be devoid of any virulence when injected into guinea-pigs. Whether such organisms are attenuated diphtheria bacilli, capable of acquiring virulent properties under favourable conditions, or whether they are specifically distinct, has not yet been satisfactorily determined. The inadvisability, however, of applying the term "pseudo-diphtheritic" to an organism which simply differs from the genuine bacillus in respect to its virulence must, I think, be admitted, in view of our ignorance, not only as to the extent to which the virulence of that bacillus may vary, but also as to the factors which are responsible for it. The settlement of this question as to the relation which the one organism bears to the other must have an important bearing on the precautions which should be undertaken in the presence of an outbreak of the disease and to this subject I propose to return again. From the point of view of diagnosis with which we are at present concerned it appears to me to be most desirable that an organism having the characters above referred to should be classed as diphtheritic, and should the mucous surface from which the organisms have been derived present any, even the slightest, sign of inflammation the case should be diagnosed as diphtheria accordingly. Such, then, are the indications which appear to be derivable from a bacteriological examination in cases where bacilli bearing a distinct resemblance to the diphtheria organism are detected.

Now what value should be attached to a negative result? I have little hesitation in saying, "Very little indeed," unless such result is confirmed by at least one, and preferably two, subsequent examinations, if possible on succeeding days. If the faucial secretion of diphtheria convalescents be carefully examined daily during the third and fourth weeks of their attack in more cases than not the results will prove more or less contradictory. The bacillus may not be recoverable for a day or two, perhaps more, to reappear again on the day following, or it may be found continuously except on some single occasion when it may escape detection. Amongst the occupants of a diphtheria ward such vagaries are no doubt sometimes to be explained by actual reinfection by another patient, but the same thing, though, I believe, less frequently, may be observed in the case of persons who are treated in a room to themselves, in which case no such explanation is tenable. The fact cannot be ignored that a negative result simply means that the observer has failed to find the bacillus, not necessarily that the bacillus is not there. I can call to mind some half-dozen cases in which the clinical and post-mortem evidences were conclusive of diphtheria, yet repeated bacteriological examination by an expert observer—in three of these instances the examination was made by one whose experience in this particular field is probably unsurpassed in this country—entirely failed to reveal the presence of the diphtheria bacillus. Three of these patients subsequently developed paralysis and two died from cardiac failure. These instances are, doubtless, very exceptional, but I simply mention them to emphasise an ever-present fallacy, the recognition of which is not by any means so general as it should be, if one may judge from the frequency with which a single unconfirmed negative result is accepted as sufficient to disprove the presence of diphtheria.

A failure to detect the bacillus, though present on the fauces, may result from an error at any one of three stages of the experiment. Bacilli may escape detection by the observer when making a microscopical examination, owing to their being but few in number in comparison with the other micro-organisms growing in the culture. Or, though present on the swab, they may fail to grow in the culture, owing to defective insemination or by reason of their reproductive capacity being lowered, if not entirely annulled, as a result of previous antiseptic applications to the throat or, finally, they may escape attachment to the swab, in consequence of their being but sparsely distributed on the mucous surface of the fauces. The chances of failure are materially lessened by exercising great care in taking the swab and by repeating the examination on one or more subsequent occasions. It is very desirable that an interval of at least two hours, and preferably more, should be allowed to elapse between the time of using any antiseptic application to the throat and the taking of the swab. This should be firmly pressed against the faucial surface at more points than one, especially where any trace of exudation can be discerned, and the swab at the same time should be rotated between the finger and thumb so as to insure its whole circumference being impregnated with secretion. And the same precaution should be observed when rubbing the swab upon the surface of the culture medium.

The exercise of care in the impregnation of the swab is of particular importance in view of the valuable evidence which may often be derived from an immediate examination of a cover-slip preparation made directly from it when stained by Neisser's method. Having regard to the fact that such examination is within the reach of any practitioner who is equipped with a $\frac{1}{12}$th inch immersion lens and a slight familiarity with bacteriological technique, early information as to the positive nature of a diphtheritic throat may often be derived on the spot without having to wait the 24 hours or so which must usually elapse before the report on the result of cultivation can be received from the laboratory. Should the examination of the swab, however, prove negative the evidence is of little value, even less so than that yielded by a single negative culture, and the laboratory report must be awaited before coming to any decision as to the diagnosis. In any case the examination of the swab, whether negative or positive, should be confirmed by subsequent cultivation. In the course of an investigation into the value of Neisser's stain on 100 consecutive cases admitted into the South-Western Fever Hospital certified as diphtheria, which I carried out some two years ago in conjunction with Dr. R. M. Beaton and Mr. W. C. C. Pakes of Guy's Hospital and which was subsequently recorded in the Transactions of the Pathological Society, the proportion of cases of proved diphtheria (both clinically and bacteriologically) in which the presence of diphtheria bacilli was revealed by a preliminary examination of material taken direct from the swab and stained by Neisser's method was no less than 37 per cent. Incidentally, I take the opportunity of recording my belief in the comparative value of Neisser's stain over all others in the diagnosis of diphtheria, a belief which is shared by many experienced bacteriologists both at home and abroad. Neisser in his original communication regarded the reaction as distinctive in young cultures grown at 35° C. Fraenkel, and more recently Lesieur, have stated their belief that, short of inoculation of animals, it is the most trustworthy test we possess. Dr. W. T. G. Pugh of the North-Eastern Hospital, after an experience of three years, during which period it had been used as a routine confirmatory test, speaks most highly of its value. Bronstein found that in 135 out of 150 cases of proved diphtheria the bacillus stained by Neisser's method was detected by direct examination of the swab and the results obtained by Beaton, Pakes, and myself by this procedure I have already referred to. In our experience Neisser's method has proved, on the whole, more trustworthy than staining by Löffler's methylene blue, though, like all others, not invariably reliable. The appearance presented by the bacillus, moreover, when stained by Neisser's method is a very striking one and on that account not likely to be mistaken by an observer of but little experience in bacteriological examination, a point of no small importance if, as I suggest, an immediate microscopical examination be made from the swab.

The disabilities to which I have referred undoubtedly detract from the authority of the bacteriological test as commonly applied and for this reason it should be regarded as of subsidiary value in cases where the clinical indications are at all distinctive. In cases, however, where the symptoms are anomalous or actually wanting the test is of the highest importance; indeed, it may be said to furnish the only criterion available. I refer especially to that class of sore-throat in which little, if any, exudation can be seen although the tonsils may be more or less enlarged and the adjacent faucial structures obviously inflamed, and to those nasal affections in which nothing beyond a mucous discharge, attended perhaps with slight soreness of the external nares, can be detected. In the differentiation of follicular tonsillitis and faucial diphtheria some assistance can often be derived from the clinical aspect of the case if attention be directed to the following particulars. In follicular tonsillitis, exudation, when present, occurs for the most part in spots, it is usually somewhat cheesy or friable in consistence, often limited in situation to the openings of the follicular crypts, and the spots but rarely coalesce into a definite pellicle. Even if they do the exudation hardly ever spreads beyond the limits of the tonsil. It sometimes appears to encroach on the pharyngeal wall, but never, as far as I know, extends on to the palate. Actual extension of membrane on to the palate or uvula is almost distinctive of diphtheria. In follicular tonsillitis it is usual for both sides to be about equally involved, whereas a diphtheritic affection is often more marked on one side than the other, and the same is true of the glandular enlargement which is apt to be more pronounced in diphtheria. The degree of pyrexia is likely to be greater in tonsillitis, and, indeed, it may be stated without fear of contradiction that the constitutional disturbance generally is likely to be more severe in follicular tonsillitis than in a case of diphtheria sufficiently mild as to be mistaken for it. Rhinorrhœa is relatively uncommon in follicular tonsillitis and the same may be said of albuminuria which is a frequent symptom in diphtheria. The occurrence of hoarseness, stridor, or a croupy cough is very suggestive, while the advent of paralysis or cardiac disturbance at a later date is, of course, confirmatory of diphtheria. By a careful consideration of all the foregoing points a satisfactory diagnosis can often be arrived at. With respect to those cases in which no abnormality can be detected beyond the presence of a mucous rhinorrhœa it is usually quite impossible to differentiate diphtheritic rhinitis from a simple nasal catarrh. Careful inspection of the anterior nasal fossæ through the external nares may reveal the presence of membrane, either on the septum or floor or the inferior turbinate, but in the majority of cases no exudation whatever is visible, even though the discharge may be teeming with diphtheria bacilli. The white appearance presented by a patch of Schneiderian mucus is a possible source of error, as it is very likely to be mistaken for an exudation unless due care be exercised in the examination. Some degree of redness, and occasionally an impetiginous excoriation of the skin immediately within the nostrils may often be detected. This, when present, is strongly suggestive of diphtheria. It is dependent upon the irritant character of the discharge, a quality also shared by the rhinorrhœa which so often follows scarlet fever in young children.

Having now referred to the chief evidences on which we have to rely in the diagnosis of doubtful cases of diphtheria, it remains to say a few words about the preventive measures which should be undertaken with the object of checking the spread of the disease. On becoming aware of a case of diphtheria among the members of a community living together in the close association which is incidental to school life, I think all must be agreed as to the advisability of immediately adopting the following precautions. 1. Isolate the patient. 2 Disinfect everything which he is likely to have worn, touched, or handled and also the room in which he has been sleeping immediately before the attack. 3. Examine the throats and nasal passages of all persons with whom he has been in especially close contact, such examination, if possible (and in a school it always should be possible) to include a bacteriological examination. 4. Isolate, or at any rate exclude, all "contacts" who are found to harbour even doubtful diphtheria bacilli on their mucous membranes and all (even though a bacteriological examination proves negative) who present any suspicious appearance of the throat or nasal fossæ. 5 Search for any other possible source of infection besides a previous case of diphtheria, not only as serving to explain the present attack but as a possible cause of fresh cases. (In this connexion the possible agency of milk, drinking utensils, cats, wind instruments, &c., should be the subject of careful inquiry.) 6. Do everything which may possibly serve to lessen the infectivity of the patient and thus shorten the period of necessary detention.

Now in school life the close and intimate association of the scholars during the hours alike of work, play, and sleep and the special susceptibility to diphtheria incidental to their age are potent factors in favouring the spread of the disease. On the other hand, the fact of their living under disciplinary control, their supervisors being well educated and presumably intelligent persons, and the special facilities for isolation which are nowadays provided at most of the public and the higher class private schools should prove of material assistance in giving effect to the various measures to which I have referred. Although I hardly think there can be much room for difference of opinion as to the preventive measures which should be adopted at the outset there are several points [illegible] the isolation of "contact[illegible] treatment of the patient [illegible] discussion.

Let us first consider what bearing the presence in the throat and nose of diphtheria bacilli has upon the patient's capacity to infect other persons. Now, if the Klebs-Löffler bacillus be accepted as the causative agent in diphtheria it would seem but logical to regard every person harbouring these organisms in their mucous membranes as a potential source of diphtheria. It does not, however, necessarily follow that the conditions essential to successful infection are actually present. If they were diphtheria would be a good deal more common than it is having regard to the frequency with which the diphtheria bacillus is present in the throat or nose of apparently healthy persons. I am using the term "diphtheria bacillus" in the wider sense which I have already referred to—*i.e.*, as including all bacilli which are indistinguishable from the Klebs-Löffler bacillus in respect to their form, staining, and cultural peculiarities but the virulence of which has not been tested. The frequency with which diphtheria bacilli are to be found in normal throats is undoubtedly influenced not only by the fact of whether or not they have been in contact with the disease but also by the [illegible] For [illegible] efully [illegible] bacilli were detected by Kober, Park and Beebe, and by Denny in 2·7 per cent. of the throats of healthy persons who by careful inquiry were ascertained to have had no recent contact with diphtheria the mean of the examinations made by different observers in connexion with various outbreaks was, for the relatively close "contacts" in the household, 51 per cent.; for the more distant "contacts" in institutions for the sick, 40 per cent.; for poorer schools in which diphtheria was present, 24 per cent.; and for the class of general "contacts," 12 per cent. In a large proportion of the cases included in these records the virulence of the bacilli was not tested but in a good many it was and of these the majority proved to be virulent; yet very few of these persons developed an attack of diphtheria.

The very interesting question naturally follows, How is it that bacilli of proved virulence may often be found living in the human throat and yet their presence turns out to be quite innocuous to their host and only occasionally a source of infection to others with whom he comes into contact? In the latter case it is not unreasonable to assume that the number of bacilli actually present in the throat would in large measure determine the chance of some being transmitted to others, whatever their ultimate fate when they get there. In the former case the question of access can hardly arise, since the bacilli are already in possession and their reproductive capacity in a suitable medium and their virulence have already been proved by experiment. It would seem only fair to infer, therefore, that in these cases the failure of the bacilli to set up diphtheria in the person harbouring them is due to the absence of certain factors which are essential to the development of their full vital activity, while their failure to set up the disease in others would appear to be chiefly ascribable to their enfeebled reproductive capacity, as a direct result of which the likelihood of their spreading the disease would be relatively slight, since the number of bacilli available for transmission would remain proportionately small, however favourable to development the conditions might be in the throat of a chance recipient. In conformity with this view we come to recognise the existence of what might appropriately be termed a state of "active infectivity" in the host as opposed to the "potential infectivity" attaching to a person simply in virtue of his harbouring virulent bacilli in his mucous membranes. In the latter case if one may be permitted a simile from another class of combatants the bacilli might be said to be on "half pay," their fighting qualities though latent being [illegible] active servic[illegible]

For the pu[illegible] to allow an i[illegible] again to mix with the community, it is highly important that the conditions which are capable of so modifying the vital activity of the bacillus as to influence the "infective capacity" of the host should be clearly recognised. From a careful consideration of the evidences drawn from an experience extending over a good many years I am convinced that the most important factor is the presence of local inflammation, whether it be of the kind which in our ignorance we call simple or that definitely associated with the presence of pyogenic organisms.

The effect of inflammation in awakening the infective activity of the diphtheria bacillus is well illustrated by the recrudescence of the local lesion which may often be observed in the diphtheria convalescent as the result of an ordinary catarrh; and in the case of the infected "contact" by his developing definite diphtheria. The same thing may often be seen when scarlet fever occurs during convalescence from diphtheria, the tonsils once more becoming covered with exudation, to be followed in many cases by paralysis. So, too, when measles occurs concurrently with, or very shortly after, diphtheria. In these circumstances the condition before the days of antitoxin usually proved fatal by reason of the rapid and excessive formation of membrane in the air passages. If we admit the power of local inflammation to arouse to a state of active infectivity bacilli previously inactive, it necessarily follows that the increase in their numbers which it implies must materially augment a patient's infective capacity, and hence on theoretical grounds one comes to regard the presence of either faucial or nasal inflammation, however slight, as a sufficient reason for prolonging his detention. Confirmatory evidence of a practical character may be derived from consideration of the circumstances under which "return cases" usually arise, the common experience being that as the result of taking a cold shortly after returning home from the fever hospital a child is noticed to present evidence of nasal or faucial mucous relaxation, with the result that other members of the family are attacked with diphtheria. It is now some 10 or 12 years since the late Sir Richard Thorne as a result of his wide experience in the investigation of outbreaks of the disease noted the fact that the appearance of genuine and widespread diphtheria was often preceded by the occurrence of anomalous cases of sore-throat, characterised by little virulence and of limited distribution. He recorded his belief in the occurrence, in connexion with such outbreaks, of what he termed "a progressive increase of the property of infectiveness," a belief which is in accord with the explanation I have suggested.

Now as there can be no object in maintaining isolation after an individual has ceased to be a possible source of infection to others, it is important to ascertain whether any means exist by which the infective capacity of a person harbouring diphtheria bacilli can be destroyed or at any rate curtailed. This result might be attained either by destroying the virulence of the bacilli or by reducing their number and consequent chance of dissemination. As a possible means to this end one naturally turns to antiseptics. That these agents, as their name implies, are capable of inhibiting, and if used in sufficient strength of altogether destroying, the reproductive capacity of micro-organisms growing under the artificial conditions of the laboratory is a well-proven fact and certainly justifies the inference that they would not be without some influence upon diphtheritic and other infective organisms, even when living under the altered conditions which characterise their existence in the human throat. This supposition is confirmed by actual observation. Not only do we usually notice that a fall of temperature almost immediately follows the adoption of efficient antiseptic irrigation of the throat in faucial diphtheria, quite apart from that produced by an injection of antitoxin, but in the slighter cases a microscopical examination of the swab taken on the day following the commencement of the treatment will commonly reveal a pronounced diminution in the number of bacteria in comparison with that observed on previous occasions Moreover, the influence of antiseptic irrigation upon the reproductive capacity of the bacilli is frequently evidenced by their failure to grow in culture, should the swab have been taken within two or three hours after the antiseptic has been used, a fact which suggests the desirability of repeating the treatment at frequent intervals.

The power of antiseptic irrigation of the faucial or nasal passages to lower the virulence of the diphtheria bacillus, however, is more doubtful. Roux, amongst others, has shown that its attenuation can be brought about *in vitro* in various ways, amongst which the impregnation of the culture medium with a trace of an antiseptic is one of the most efficient. From these experiments we might argue that such might not improbably be effected in the human subject; but having regard to the fact that a partial reduction of virulence of the bacilli takes place in many cases normally during convalescence its occurrence, I believe, has never been satisfactorily established. Now out of the long and formidable list of antiseptics I prefer for irrigation of the fauces a solution of chlorine. Not the liquor chlori of the Pharmacopœia but an acid solution of chlorate of potash containing free chlorine. The preparation is as old as the hills, but I know of nothing better or indeed so good. The solution I use is prepared by pouring five minims of strong hydrochloric acid on to nine grains of the powdered salt and shaking up with an ounce of water gradually added. This during the acute stage of the attack is used mixed with an equal bulk of hot or iced water every two to four hours according to the severity of the case and whether or not the patient actively resists the treatment. During convalescence it may be used less frequently. For the nasal passages, in consequence of the somewhat irritant effect of the chlorine gas, I usually employ a solution of boric acid. An alternative to either of the above is a 0 5 per cent. solution of formalin, but its use is by no means pleasant. The value of chlorine solution has quite recently received confirmation from the results obtained by Dr. Mervyn H. Gordon in the course of an investigation into the comparative antiseptic effect of various solutions upon microorganisms present in the mouth. Some of the best known antiseptics were tested by Dr. Gordon and of these chlorine came out at the top of the list, a fact which was to me very satisfactory. Another agent which is capable of exerting no small influence in lessening the infective capacity of the diphtheria convalescent is free oxygenation. It acts beneficially both by its direct restorative effect on the system and by tending to render the tissues less favourable to the maintenance of bacterial existence.

On theoretical grounds we must admit the desirability of keeping apart from the community all persons so long as they harbour diphtheria bacilli, whether such have resulted from an attack of diphtheria or have been acquired simply by contact with the disease. Unfortunately, it is not always practicable to do so on account of the long persistence of the bacillus in some individuals. Although there are practical difficulties in the way of enforcing a rigid isolation for any great length of time in the case of some persons, particularly those who are bread-winners, the same objection could not be urged in respect to school attendance and, whether a day pupil or a boarder, every scholar should be excluded from school until the throat and nose, as a result of three negative examinations, may be assumed to be free from diphtheria bacilli—that is to say, bacilli indistinguishable from the Klebs-Löffler organism in respect to their morphology, staining, and cultural reactions. The usually accepted view as to the relation of the Hofmann bacillus—viz., that it is a distinct organism and incapable of ever being converted into the Klebs-Löffler bacillus—I have already referred to. That the Hofmann bacillus, however, should play no part whatever in the development of diphtheria is perhaps not equally clear. The fact that certain observers have described outbreaks of apparently infective sore-throats in which the Hofmann bacillus alone was present and that in some of the cases fibrinous exudation *plus* Klebs-Löffler bacilli were also detected would appear to suggest that in certain circumstances the Hofmann bacillus may act as a predisposing factor in the development of the true disease. Dr. Joseph Priestley has recently described an outbreak of infective throat illness in a school in Lambeth characterised by tonsillar exudation and pyrexia in which the typical Hofmann bacillus and no other was present in 33 out of the 43 attacks. The metropolitan branch of the Society of Medical Officers of Health after careful consideration of the evidence has lately affirmed its belief "that cases clinically resembling diphtheria but in which the Hofmann and not the Klebs-Löffler bacillus is found are infectious and that, consequently, the usual precautionary measures of notification, isolation, and disinfection should be undertaken." Whether the Hofmann bacillus is competent to set up an infective membranous angina or not it would certainly be impracticable, in view of its comparative ubiquity, to make the simple fact of its presence in the throat or nose a test of the necessity for isolation. Roux and Yersin found it present in 44 per cent. of the children attending a school and in 27 per cent. of the patients in a hospital ward in which in neither instance diphtheria had occurred for many months previously. Cobbett detected it in the throats of 23 per cent. of a large number of healthy persons who had not been in contact with any known diphtheria, the proportions in well-to-do and poor persons being 4 per cent. and 25 per cent. respectively, while amongst 2198 non-infected "contacts" examined by Cobbett and Graham-Smith the Hofmann bacillus was found in nearly 40 per cent.

The average length [illegible] are said to persist in [illegible] eight to 24 days aft[illegible] The average period in a series of cases examined by myself was 20 days, but its duration in patients living in diphtheria [illegible] [illegible]ore protracted than in those [illegible] In a fair number of cases [illegible] weeks, in a few more than eight weeks, and in exceptional instances bacilli may be detected as long as three months after the attack. The longest time on record is, I believe, 363 days. The presence of adenoids appears to be often responsible for undue persistence of the diphtheria bacillus, just as they are a frequent source of chronic nasal discharge. Great care should be taken that the naso-pharynx is free from bacilli before any [illegible] their removal.

[illegible] [illegible]e period of potential [illegible] [illegible]theria bacilli on their mucous membranes and of lessening the chance of their actually infecting others I would strongly recommend the efficient flushing out of the fauces of all infected "contacts" three or four times a day with some reliable antiseptic solution, preferably chlorine, by means of an indiarubber-ball syringe, and in the case of a person actually suffering from the disease the same procedure may with advantage be instituted from the outset as a matter of treatment. No amount of gargling, spraying, or swabbing will be equally effective. In respect to the nasal passages an equally good result, unfortunately, cannot be obtained, since it is practically impossible effectually to reach their various diverticula. These, as might be expected, provide an excellent retreat for the bacillus. During the period of isolation as much time as possible should be spent in the open-air and out-of-door exercise should be encouraged. I should think that the instances where any real difficulty is likely to be encountered in carrying this out must be very uncommon, especially in good class schools where some facilities for segregation are usually existent.

The injection with antitoxin of all "contacts" proved to be harbouring diphtheria bacilli has been recommended but it is quite without effect in hastening the disappearance of the bacilli. In so far as it is competent to avert the danger of an attack and so be a means of restricting the multiplication of organisms capable of spreading the disease the injection of antitoxin is worthy of consideration. I am not prepared, however, to recommend its indiscriminate adoption as a prophylactic measure in the case of apparently healthy "contacts" living under skilled observation simply because diphtheria bacilli are present in their mucous membranes. In the case, however, of schools for very young children, particularly of the poorer class, there is a good deal to be said for the practice. Antitoxin should always be given, without exception, in the case of an infected "contact" who presents any indication, however slight, of either faucial, nasal, or laryngeal inflammation.

HOW TO TREAT A CASE OF INSANITY.[1]

BY ROBERT JONES, M.D., B.S. LOND., F.R.C.S. ENG.,
RESIDENT PHYSICIAN AND SUPERINTENDENT, LONDON COUNTY ASYLUM, CLAYBURY.

INSANITY is more easily described than defined and it is significant that the most modern authorities do not attempt to give a definition. In a previous lecture here[2] it was pointed out that the age, circumstances, and surroundings of the individual and the period in which he lived were all necessary factors in the determination of insanity. The practical point to be considered, however, is one of conduct, and the conduct of an ordinary member of society which tends to the detriment of himself or his neighbours may be such that his sequestration becomes justifiable or even necessary and obligatory. Society, acting for its own protection, establishes certain rules and regulations of a self-restraining character which the various members, having a common object in view, abide by and are [illegible] the common welfare. Failure to [illegible] rules which the reflective wisdom [illegible] down entails punishment, but this may be mitigated, if not altogether avoided, when by incapacity through disease or in some other way the offending member fails to apprehend the nature or the quality of the act he has committed in infringement of the law. This mitigation implying as it does an exculpatory plea, connotes mental unsoundness, a weak or an ill-balanced mind, and involves either a generous interpretation of the law or the vexed question of irresponsibility, a subject which for nearly two centuries has been a debatable theme between medical and legal minds. The reason for the appearance of the legal authority on a medical point was due to the fact that medical men, in order to bring an insane person and his property under control, had to invoke the aid of jurisdiction. The question of responsibility was discussed by Hale several centuries ago. He insisted that the test of criminal responsibility should be the level of understanding of a child of 14. It was pointed out that this meant the identification of "healthy immaturity" with "diseased maturity" and later, in 1723, Tracey insisted that to establish the plea of irresponsibility the person should be totally deprived of understanding and memory and be as an infant, a brute, or a wild beast. Kenyon suggested, in 1800, that the question of insanity should be limited to the time the act was committed and such was the custom until, in 1812, Mansfield urged that the criterion of responsibility should be a knowledge of good and evil. In 1843 Tindal recognised partial insanity by insisting that the question of right and wrong should only be considered in regard to a particular act, but it was pointed out that the affection and the will may be diseased without the reasoning powers—thus recognising moral insanity; but Stephen pointed out that a man could not know the nature and the quality of an act who was deprived by disease of the power of passing a rational judgment on the moral character of such an act. Section 116 of the present Lunacy Act recognises disease or age as causing insanity and incapacity to manage one's own affairs. I have very cursorily referred to this question of responsibility which may on a future occasion be very much further elaborated. The first legal enactment dealing with the insane is an unrepealed statute, *De Prerogativa Regis*, 17 Edw. II., by which, as a survival of feudalism, when everything belonged to the king or the lord, the care and custody of the insane belonged to the Crown By this early statute the king took the rents and profits of an idiot's lands for his own use during the life of the idiot, subject only to an obligation to provide the owner with necessaries. In the case of a lunatic the king was a trustee for his benefits and those of his family. Juries, therefore, where they could, avoided a verdict of idiot in the two forms of inquiry then in vogue—viz.: *de iodota inquirenda*, and they founded their conclusion upon the alternative *de lunatico inquirendo*, a form which survives at the present day Hence it became very desirable that some definite distinction should be drawn between these two states and, with the yearning for definitions characteristic of the legal mind, great lawyers contrasted *non compos mentis* with *fatuus naturalis* by forming a definite limitation to the capacity of an idiot. Under one set of expositors the mental capacity of an alleged idiot limited him to telling his age, stating who his father and mother may be, and to counting 20 Another set of authorities determined his idiocy by his ability to name the days of the week and measuring a yard of cloth The Idiots Act of 1886 put an end to this definite limitation by recognising the fact that an idiot was educable and removing him from Coke's definition that an idiot was "one who from his nativity by a *perpetual infirmity* was *non compos mentis*." The tendency of modern law has developed in the direction of deciding the capacity of a person alleged to be insane by considering this capacity with reference to the kind of conduct which brought his mental condition into question, and to limit the inquiry to the time at which the abnormal phase of conduct occurred. By the present Lunacy Act, passed in 1890, evidence in proof of mental unsoundness at an inquisition is limited retrospectively to two years before the date of the inquiry, and the Act also makes it necessary to consider the state of mind of the alleged lunatic at the time the inquisition is held.

Terminology, distinctions and import.—Before we enter upon the question of dealing with cases of insanity it is essential to be clear in regard to three terms that are frequently used in speaking of insane patients and which should be definitely understood—viz.: *illusion*, *hallucination*, and *delusion*. By an *illusion* is meant a real impression produced upon the sensorium through one or other of the senses, but appearing in consciousness very different from the actual fact; an illusion is *objective* in relation to the sensorium and the element of logical inference is slight. *Hallucinations* arise when no impression has been produced upon any of the senses and is a new creation due to an abnormal condition of the sensorium itself; it is *subjective* in relation to the sensorium. It is a false perception arising from within and is largely independent of an external stimulus. Thus, if the tolling of a bell be heard and be interpreted as the sound of human voices it is an illusion; but when no sound is audible and human voices are declared to be heard then it is a hallucination. *Delusion* pertains to the *mind* only and not to the *senses*. It is due to a perverted or morbid mental action, which prevents the subject from realising the falsity of his belief, either by the evidence of his senses or otherwise. A man calling himself the Creator or the Saviour, or stating that he is 10,000 years old labours under a delusion. The types and varieties of delusions are almost endless; sometimes they constitute the sole disorder, which is then termed "delusional insanity." When limited to one topic they form the monomanias—the popular conception of insanity. Many of these delusions become systematised and enlarged, as is seen in the inmates of asylums for the insane.

---

[1] A lecture delivered at the Medical Graduates' College and Polyclinic, Nov. 17th, 1903.

[2] Jan. 16th, 1903, Mental Unsoundness amounting to Certifiable Insanity and its Diagnosis, a lecture delivered at the Medical Graduates' College and Polyclinic, THE LANCET, June 6th, 1903.

The terms above referred to are of pathological importance in their natural order, for *hallucination* probably indicates a deeper reduction than an *illusion*, which may only be dependent upon some peripheral abnormality of the special senses. *Delusion*, again, indicates that a definite combination of false impressions has become the basis of a belief which cannot be reasoned with, and may indicate some chronicity, for it is of a somewhat persistent nature and involves more or less elaborate reasoning processes. These perversions of the senses and intellect form the substratum of thought in the insane and they serve as motives to action precisely as they do in the sane. It is necessary, therefore, to seek for them and to ascertain how far these morbid thoughts influence the conduct which is under consideration. Much assistance may be obtained by bearing in mind the comparison between the present mental condition and that which characterised the patient formerly. Lord Eldon laid down a doctrine which has been accepted by his successors, that "mere weakness of character, mere liability to impulse or susceptibility of influence, good or bad, mere imprudence, extravagance, recklessness, eccentricity, or immorality—no, not all these put together would suffice to establish a verdict of insanity; except upon a review of the whole evidence they could be referred to a morbid condition of the intellect." What to most minds would be more conclusive of a "morbid condition of the intellect" than an unlicensed indulgence in the irregularities described above? It is essentially in the contrast between the present and the past that insanity is diagnosed, and the fact that such moral departures, as above referred to, come on in persons in whom an opposite, or at any rate a different, character formerly prevailed, is strong circumstantial evidence of insanity. In clearly marked cases of hallucinations or delusions there is, as a rule, no difficulty of diagnosis, but cases of rambling incoherence and delusions are not infrequently met with which require some elucidation and reference.

Diagnosis.—It is not expected that a medical man whose experience is not constantly with the insane shall diagnose the many and subtle varieties of insanity with the readiness of one versed in the treatment of every form of mental disease; but it is expected of him that he should not deprive of his liberty and incarcerate as insane a person who is suffering from the effects of fever or other temporary inflammatory states, as has been done on more than one occasion within my experience. For instance, the delirium of fevers such as typhus and typhoid has been mistaken for acute mania. I have seen the delirium of typhoid fever, as also that of pneumonia, mistaken for such and a certificate issued accordingly. Delirium is always a sign of nervous disturbance and it may be caused by a general affection of the whole economy operating upon the nervous system, as in the above-named fevers, in scarlet fever, small-pox, severe inflammation of the lungs or meninges from severe injuries, through the effects of alcohol or chloroform, and in uræmic poisoning. In high fever and in long protracted febrile states delirium is exceedingly common before a fatal termination, but in nearly all cases it is preceded for some days by symptoms characteristic of the disease on which it is dependent. The character of the delirium is in most cases incoherence or a quiet rambling and it occurs generally at night when the patient is drowsy and no one is addressing him. Frequently associated with it are hallucinations of vision. The temperature is often a reliable guide. In delirium it is high and there is a quick pulse, furred dry tongue, parched skin, injected conjunctivæ, and high-coloured urine. These conditions are the exception in the most common forms of acute mania, and it may be laid down as a good rule that in cases where the temperature is distinctly above the normal the examination should not be regarded as complete until it is ascertained whether inflammatory action in one of the principal organs or one of the continued fevers be not the cause of the mental disturbance.

Acute meningitis has been mistaken for mania; the mental phenomena greatly resemble one another; but the headache, vomiting, intolerance of light and sound, with suffused eyes, contracted pupils, and the high temperature should warn us. Delirium tremens has been mistaken for insanity but the finer distinctions between insanity requiring a certificate and transient delirium tremens are rarely drawn. The sudden and impulsive motor disturbances of alcoholic intoxication not infrequently require restraint, and it is not improbable that residence in a well-conducted asylum may prove very salutary to the slaves of alcohol; still, in my opinion, it is improper that such cases should be classed with the insane, for the stigma clings to them and militates much against their future prospect in regard to sobriety when they leave the asylum, as also against their material prosperity when discharged. Speaking generally, the diagnosis of delirium from the varieties of mania rests much more on the co-existence of gross physical disease accompanying the former than on any marked differences in the *mental* symptoms.

It is within my experience that insane persons may only display insanity at intervals and in the society of certain persons. I have known insane persons to have sufficient cunning to exercise self-control in the presence of strangers, hiding their delusions for a long time, although these were, in one recent case, of the nature of aggravating aural hallucinations, and in another of marked morbid abdominal sensations. The different varieties of insanity need hardly be considered here in regard to diagnosis, but it may be mentioned that general paralysis is almost invariably attended with the Argyll-Robertson phenomenon, and it needs asylum or hospital care; whereas insanity accompanying confinement should, in my opinion, be treated, for six weeks if possible, outside an asylum or hospital before a certificate is deemed necessary.

Examination of the insane.—This must necessarily vary with each case and according to the social status, habits, mental peculiarities, and other features of the patient. When called upon it is, in my opinion—although some differ from this—far better for a physician to be introduced in his actual capacity as a medical adviser rather than be announced as "Mr.," concealing his real character and making it appear that a visit is being paid casually. A patient is more likely to commit a dangerous act through this deception than by being actually informed that a physician was visiting. When in the presence of the patient it is best to endeavour to gain his confidence by a few well-chosen general observations and a great guide will be found in the physiognomy or the general expression of the countenance, peculiarities of dress, arrangement of the room, &c. Following these preliminaries the investigation should extend to medical points, covering the special senses, such as noises in the ear, voices or whispers, and what they say. A direct question: "Do you answer them back?" may elicit marked delusions otherwise concealed or suppressed, although based upon definite aural hallucinations. Disturbances of common sensation, such as animals creeping over the skin, electricity and galvanism, or "marconigrams" transmitted may be elicited, or possibly delusions may be evoked from answers to questions relating to the home and family, to business prospects, or religious views. Great public movements, important questions, or sensational news almost always interest and affect the mentally unstable, and there are at the present time persons recently admitted into Claybury either as Miss Hickman herself, or those specially commissioned to search for her, or who have elaborate theories as to her disappearance and death. During the interviews with a mental case sufficient will be noted in regard to the memory or the faculty of ideation to justify conclusions, but if the patient be reticent or indignant with the "idea of being ill" a tactful sympathy with him may bring out marked delusions of persecution or suspicion which *the friends themselves* and *those most intimate* with him had failed to observe fully. A patient disinclined to converse may express his views more freely in writing, and it is well in cases of marked reserve to direct the inquiry to suicide, as suicidal attempts are not infrequently contemplated or made in patients disposed *to mental depression.* If this be so care should be taken that the patient is never left by himself. Finally, the family history, although difficult to obtain and a delicate inquiry, is often found to be invaluable for clearing the diagnosis. Any history of nervous diseases in the family—the different neuroses being strongly hereditary and often mutually interchangeable—may be of great assistance towards forming a conclusion.

Course to adopt and in what form.—Having said so much the urgent question is: "What is to be done?" Without enumerating the different forms of insanity and their detailed treatment it may be stated generally that some varieties are suitable for home treatment. These are especially forms of insanity referred to malnutrition, such as those caused by excessive lactation or the conditions accompanying the puerperal state; transient toxæmic states, such as those *due* to *drink* or *drugs,* and the temporary insanities of young persons; quiet and harmless weak-minded cases; and certain cases of general paralysis in the last stage, whose friends are desirous of avoiding the much-felt stigma when a father or husband is said to have died in an asylum. With these exceptions it may be very definitely asserted that the treatment of the patient is much better away from home, and such cases as early general paralysis, insanity associated with epilepsy, any acute insanity not the foregoing recommended for home treatment and acute exacerbation in an otherwise quiet and chronic case, melancholia with refusal of food—for such are potential suicides,—cases of chronic delusional insanity or monomania with systematised fixed delusions—for such are potential homicides—these are all better treated in institutions. They require very special supervision and the sooner they are removed from home the better for themselves and their friends.

Classes of patients and methods of dealing with them—As is well known, cases of insanity are divided, according to law, into three classes. For each of these classes there is also a different law, so that in lunacy there is indisputably "one law for the rich and another for the poor." The three legal classifications are: (1) private patients, (2) pauper, and (3) criminal. Taking these classes in their inverse order, firstly, criminal lunatics need not be considered, as before being certified they are objects of special solicitude elsewhere. There are two classes of them, called respectively (*a*) the "Home Secretary's lunatics"—i.e., criminals who become insane before or after trial and who may be sent to an asylum by the Home Secretary's order; and (*b*) the "Sovereign's lunatics"—those who are insane on arraignment or "found guilty but insane." These latter are consigned to Broadmoor during the King's pleasure. Pauper lunatics are those who cannot pay, or whose friends have not the means to pay, for their maintenance, amounting at the lowest estimate to about £1 per week. To be admitted into a county asylum as a pauper lunatic the procedure is simple. The police constable or relieving officer of the district is informed, the parish medical officer fills up the certificate, and a justice orders the patient to be detained. I am not infrequently asked how a lunatic who may be annoying a certain person can be dealt with, as under the Act it is no one's duty to give the information. The friends may refuse the petition that the person should be removed and the landlord may also refuse, as whoever signs the petition enters into a contract to visit every six months. In such a case a private patient can be dealt with as if a pauper, and paragraph A covers such cases. If a person is suspected of being a lunatic a private letter addressed to the Commissioners in Lunacy may be sufficient to commence an action. The Commissioners have caused inquiries to be made under a section of the Act dealing with an alleged lunatic not under proper care and control.

Reception of pauper lunatics.—An order made for the reception of a lunatic if made by a justice otherwise than upon petition is called a "summary reception order." Such orders may be made as follows: A, lunatics not under proper care and control or cruelly treated or neglected; B, resident pauper lunatics; C, lunatics wandering at large; and D, lunatics in workhouses who ought to be sent to an asylum.

A. Every constable, relieving officer, or overseer who has knowledge that any person within his district who is not a pauper and not wandering at large is deemed to be a lunatic and is not under proper care and control or is cruelly treated or neglected must within three days swear such information before a justice being a judicial authority under the Act. *Upon such information on oath of any person whomsoever* the judicial authority may visit the alleged lunatic and must, whether making such visit or not, direct two medical practitioners separately to examine him and to certify as to his mental state. The judicial authority upon being satisfied that the said information is correct and that the person is a lunatic, and a proper person to be detained under care and treatment, may direct the lunatic to be received and detained in an asylum named in the order, and to which, if a pauper, he might be sent under the Act. (After admission into the institution he is classified as a pauper until it is ascertained that he is entitled to be classified as a private patient.)

B. Every medical officer of a union who has knowledge that any pauper resident within his district is deemed to be a lunatic and a proper person to be sent to an asylum must inform the relieving officer of the district within three

mental state, and if satisfied that the person is a lunatic and a proper person to be detained under treatment, may by order direct his detention in the institution named therein.

C. Every constable, relieving officer, or overseer who has knowledge that any person (whether a pauper or not) wandering at large within his district is deemed to be a lunatic must immediately apprehend or cause him to be apprehended and taken before a justice, unless the justice examines the alleged lunatic where he is (within his jurisdiction). The justice must examine him and call in a medical practitioner to certify as to his mental state, and may, if satisfied that he *is a wandering* lunatic and a *proper person to be detained* under care and treatment, by order direct his detention in an institution to which pauper lunatics from that place may be sent under the Act. (The lunatic is then detained as a pauper until it is ascertained that he is entitled to be classified as a private patient.)

D. Every relieving officer upon receiving notice from the workhouse medical officer that a pauper in the workhouse is a lunatic and a proper person to be sent to an asylum must
within three days give notice t
where the workhouse is situat
in a county not including the
belongs) The justice must
in a medical practitioner to certify as to his mental state, and if satisfied that the person is a lunatic and a proper person to be sent to an asylum may by order direct his detention in the institution named therein.

(Section XXIII.) A reception order may also be made by two Commissioners in Lunacy in the case of a lunatic not in an institution or workhouse.

Note.—In each case the reception order must be accompanied by a medical certificate (in Class A two certificates are required) and dated within seven clear days *after* the date of the medical examination. The justice or judicial authority making the order need not necessarily be the justice or judicial authority to whom notice was given by the relieving officer, but must have the same jurisdiction.

Removal to workhouses in urgent cases.—If it is necessary for the public safety or the welfare of the alleged lunatic that before the above proceedings can be taken he should be placed under care and control, the relieving officer or constable may remove him to the workhouse of the union in which the alleged lunatic is, and, unless there is no proper accommodation, he must be received and detained therein while the proceedings are being taken, but not for more than three days unless the medical officer of the workhouse signs a certificate under Section XXIV. (1) or a justice's order is obtained for his detention therein. Three years' *consecutive residence* in a locality constitutes what is termed "a settlement" and entitles a pauper patient to admission into the asylum provided for that particular district. Pauper patients are cared for by the counties or *joint counties, city* or borough authorities in England in their several institutions, but workhouses also form one of the institutions for the care of the insane poor, and Leavesden, Darenth, Caterham, and Tooting Bec asylums are examples of those for London.

Reception of private patients.—The mode of reception for private patients, to which we shall presently refer, is the same for all, whether received into county asylums or into institutions especially provided for them. There is another class of patient, not included in the three distinct classes previously mentioned—namely, the *bonâ fide* patient who is not certifiably insane. He may be conscious of a coming recurrent attack or he may feel a dread or awe of an impending mental breakdown for the first time. He may be safe with the minimum of supervision but not safe alone. Such a person may enter a registered hospital or a licensed house as a voluntary boarder. He merely expresses his wish in writing and this must be sanctioned by the consent of the Commissioners in Lunacy for a registered hospital or a justice must grant permission into a licensed house, but the boarder, once admitted, is free to leave the institution by giving 24 hours' notice in writing; or, on the other hand, he may be certified by direction of the Commissioners in Lunacy although he has given notice to depart. In such a case the patient not infrequently thinks that he has been tricked and it is certainly not a satisfactory procedure. At present no legal facilities exist for private patients to become voluntary boarders either in county or other public asylums where private patients are received.

Accommodation provided for the different classes.—There are suitable "institutions" for each of the classes enumerated and they may be summarised as follows: (1) institutions, a term used in law to signify (*a*) asylums, (*b*) registered hospitals, and (*c*) licensed houses; (2) workhouses; (3) houses in which patients are "boarded out"; and (4) private houses (unlicensed) for not more than one patient, called by law "single patients." These are the four classes of reception houses recognised by law for insane private patients. (*a*) Asylums, as already stated, are county, joint-counties, city, borough, or district asylums. (*b*) As to registered or lunatic hospitals, they are institutions such as Bethlem and St. Luke's Hospital in London, St. Andrew's Hospital in Northampton, and the Cheadle Royal Asylum near Manchester. There are 14 of these institutions in England and Wales. They are registered by the Commissioners in Lunacy. They were originally endowed by private philanthropy, and they receive paying as well as free patients, the latter usually belonging to the middle classes, the balance of profit derived from accommodating paying patients being applied to the support of those unable to pay. These hospitals are managed by committees and do most excellent and much appreciated charitable work. (*c*) The Lunacy Act of 1890 enacted that no more houses or private asylums should be licensed—thus creating a monopoly in these establishments—but it granted permissive power for local authorities to build such accommodation for private patients as they might deem necessary. Several counties and some cities and boroughs availed themselves of this and have provided inexpensive accommodation at low rates of payment for private patients, the charge made varying from £1 to £2 per week. Accommodation is provided in one of the London asylums for female private patients at a charge of 16*s.* per week and for male patients at from 30*s.* to £2 2*s.* per week.

Licensed houses or private asylums are generally managed by a resident medical proprietor.

What is called "single care" or an unlicensed private house is when a patient is certified (two certificates, the petition, and the magistrate's order) to the single care of any one person; but no one, without the special consent of the Commissioners in Lunacy, can take more than one certified patient. Special stringent reports and conditions are prescribed by the law in the case of persons under "single care" and if the house selected be that of a registered medical practitioner he is not allowed by law to be the visiting medical attendant. Provided that no one makes a profit by keeping the patient the friends or relatives may take a house and place it under the charge of nurses or attendants, with a medical man to visit.

These are at present the legal institutions for the treatment of private lunatics, but some consulting physicians admit that, for reasons of pure humanity, they may evade the law and send a mental patient uncertified—who, by the way, may be certifiably insane—into the care of nurses or a medical man who receives payment. As it is illegal to receive profit from keeping a lunatic uncertified—i.e., a patient certifiably insane but not certified—this practice has led to prosecutions. Hope is expressed that fresh lunacy legislation may be passed to permit of a mental patient in the stage of incipient insanity being cared for, at adequate payment, under proper restrictions, and presumably under the care of those who have given proof of special experience and personal fitness, and who can in addition show a distinct recommendation for the character of the household and the home.

Patients suffering from incipient insanity are not infrequently recommended by the neurologist to travel. They go forth and in many cases they never return. Upon this point it is not too much to say that valuable lives which might be restored are lost through the failure of the person consulted to apprehend the nature of mental depression and the gravity of the consequence of sending such a person travelling away from home. There is no justification for ordering a person with any symptoms of actual insanity to leave home on a sea voyage or a journey.

Perhaps it may be mentioned here that no mechanical restraint may be used—except for medical or surgical reasons, or to avoid danger to himself or others—in the case of certified patients, and when used notice of the same must be sent to the Commissioners in Lunacy. About this matter of mechanical restraint the official authorities are most particular. Restraint is rarely used in any "institution." Since the opening of Claybury—a period of ten and a half years, during which time nearly 10,000 patients have been treated—restraint has never once been used to control a violent patient.

Treatment.—As to the treatment, the description of the symptoms and course of Hamlet's illness suggest the remedies—

> "And he, repulsèd,
> Fell into a sadness; then into a fast;
> Thence to a watch; thence into a weakness;
> Thence to a lightness; and, by this declension,
> Into the madness whereon now he raves,
> And all we wail for."

Whether the patient be treated in his or her own home, or in any of the "institutions" provided under the Lunacy Act, adequate nursing is essential and must be provided. In a private house where a patient is more difficult to control than in an asylum, two or more nurses will be required by day and a night nurse will also be necessary. Insane persons, when treated in their own homes, often develop a mistrust in members of their own family and this may lead to a tragic end. For some cases one nurse will be sufficient, more especially if the nature of the case will permit of the nurse sleeping in the patient's room at night. A mental nurse is absolutely necessary for a mental case, and preferably a young person with asylum experience whose record of training is supported by certificates in mental nursing, for only those accustomed to and familiar with the insane are of any service in this illness. It is by the help of efficient nursing that an attack of insanity may be cut short, the risk of accident or suicide averted, the anxiety of relatives and friends relieved, and valuable lives restored to reason. Tact, watchfulness, untiring patience, sympathy, geniality, and good temper are essential qualifications for nursing the insane, and a good attendant is of incalculable value in the home treatment of any case of insanity. Similar previous experience is, therefore, an essential qualification. Ordinary hospital nurses are totally unfit for nursing the insane and they should not be employed. There are numerous nursing homes and institutions where self-reliant, prudent, and thoughtful nurses—total abstainers most of them—can be obtained at what may be almost called a moment's notice. If mental nurses be not total abstainers it is a rule with them in private nursing not to take any alcoholic stimulants while on duty.

At the present time before a well-to-do person is placed in an asylum home treatment is given a fair trial, so that in the early stages of mental disease every effort in such a case should be made to promote recovery through the aid of private nursing. The risks are usually greater in a private house, from stairs, open windows, knives, razors, &c. Windows must be blocked, possible weapons removed, locks taken off, superfluous furniture discarded, pegs, &c., removed, and all medicines, drugs, and poisons placed securely under lock and key. When patients are treated in their own homes the vigilance of friends not infrequently aggravates, if it does not suggest and develop, suicidal impulses. When a patient undergoing home treatment shows any suicidal tendency that patient should never be left alone or out of sight for one instant. He should be followed even to the lavatory, he should have his food specially cut up for him, no strings should be permitted to the clothing, and someone should sit up and be on guard all night. Daily written notes of the temperature, food taken, sleep obtained, exercise in the open air, and any change in the mental symptoms or the body weight should be recorded to, and required by, the medical attendant. As to sleep, this is often the greatest trouble; sleepless nights possibly mean noise, excitement, and violence by day. These latter are the symptoms which as a rule determine asylum treatment.

The remedies which favour sleep are either *direct*, which *act primarily upon the central grey matter or its blood-supply*, or *indirect* which are not in themselves narcotics but favour sleep by removing disturbing elements. Among the latter are iron which by relieving anæmia also relieves the *restlessness and sleeplessness often accompanying it.* Iron has exercised marked benefit in cases of epileptic insomnia. Digitalis, by adding tone to the cerebral arterioles, effectually prevents passive congestion in lax arteries when the patient occupies the recumbent position; it also probably causes a due amount of cerebral anæmia. Tartar emetic lessens arterial pressure and acts as a vascular sedative; it is very useful in the restlessness of sthenic inflammations and when combined with opium it is very effective in lessening sthenic delirium. Alcohol, administered with easily digestible *nourishment during periods of* exhaustion, especially just before retiring to rest, is a most valuable sedative.

Of the direct sedatives bromide of potassium is certainly *the simplest if it be not the most efficacious.* It is very useful in the insomnia of overwork and the restlessness arising from reflex affections; it can be given alone in 20-grain doses three times a day or in combination with chloral (15 grains) which is the best remedy for simple insomnia, and there are no unpleasant after-effects from the combination. If chloral hydrate is prescribed for old people care should be taken to have a hot-water bottle in the bed and the feet kept warm. Opium has the disadvantage of (1) losing effect from the toleration which follows repeated doses and of (2) *setting up digestive troubles, but it is very* useful as an anodyne, either in 10 minim doses of the tincture, or in subcutaneous injections of morphine, one-sixth to one-half of a grain. Opium is very suitable in cases of sleeplessness in *restless* old people and seems to act on them as a sedative stimulant. Sulphonal in 20 grain doses *three times a day,* taken in warm milk or beef-tea, acts as a marked muscular depressant, but it is apt to cause intestinal trouble and its action is cumulative. It is best given for continuous excitement, *for a few days at a time,* and then withdrawn. To control sudden violent aggressive motor excitement it is of no use. Some chronic noisy cases do very well with a dose of sulphonal at night. Trional in similar doses is less depressant but is also an intestinal irritant owing to its insolubility. There is no better remedy than a hypodermic injection of hydrobromate of hyoscine, from $\frac{1}{200}$th to $\frac{1}{50}$th of a grain. The effect is very fleeting but it is immediate; the patient is as excited as ever the next day or even in a few hours, but care should always be taken to visit the patient *frequently after the* injection, and it may be advisable to combine with the hyoscine a subcutaneous dose of strychnine. Hyoscine is used less to procure sleep than reflexly to cause muscular paralysis. Paraldehyde in one drachm doses is a valuable sedative for old people, or those in whom the circulation is feeble; it does not weaken the heart; the pulse gains in strength under its action; it is not an irritant, but, on the contrary, is usually borne well by the stomach; it is superior to chloral for the *insomnia of alcoholic delirium*; and *as a* hypnotic in cerebral affections it is most useful. Noisy paretic dementia, the multiform manifestations of hysteria, and the convulsive neuroses are all greatly improved by it and it can be taken alone in water or with milk or beef tea. Cannabis indica, in combination with bromide of potassium, has been recommended by some for epileptic excitement, nervous insomnia, or acute mania, but my experience fails to recommend it. In some women it produces very unpleasant hallucinations, and the benefit, reported in the *experience of others, may perhaps be due to the simple* bromide, often used in combination with it in the formula "bromidia." Bromide of potassium in large doses of from four drachms to one ounce has been recommended for maniacal excitement. Perhaps the best cure for sleeplessness as well as motor excitement *is open-air exercise. Sleep can* often be obtained by special attention to diet and artificial feeding may become most important. When a patient refuses food, gentle and firm persuasion may overcome the refusal; beyond this the nurse should never go. No apparatus for forcible feeding should be employed by any other than a medical man—who chooses his own method, either by the mouth or with the use of the nasal tube. Feeding is the sheet-anchor of treatment in many cases of early toxæmic insanity, such as the puerperal form, and artificial feeding should be resorted to early and often, during every quiet interval and at each opportunity, to compensate for the profound exhaustion—often intense—caused by restlessness and *maniacal delirium.*

One of the most important points in treatment is attention to the state of the bowels, for constipation is a most prevalent irregularity in the insane. Calomel in doses of ten *grains is easily borne* and is probably the best purgative. Croton oil, even in as large a dose as two minims, is often ineffective. It is difficult to get the insane to take tabloids or pills and almost impossible to give these with food—even if it were desirable. Epsom salts or some of the foreign well waters such as "Hunyadi Janos," are very effective when given daily and in free doses—generally twice or three times the dose required for a sane person.

Restraint, to which reference has been made, should never be permitted in a private house; when it appears necessary *the time for home treatment is over* and asylum care is urgently indicated. Asylum treatment often renders unnecessary the excessive and damaging used of narcotics, calmatives, and restraints, which are so often used to prevent *the noise and destructiveness of patients treated in their* own homes. The treatment in asylums consists in diverting the morbid mind into healthy channels, the removal of disturbing causes, and the encouragement and example to industry afforded by those in attendance. Perseverance, attention, uniform kindness, yet firm determination, are characteristics always appreciated in the asylum nurse. It is not too much to say that the regular routine of asylum life tends to favour regular processes of thought and reflective action which are often the first symptoms of recovery in patients who have suffered from delusions. In *the asylum* there is constant, but not too direct, watchfulness and supervision combined with forbearance and respect. These characteristics form what is usually termed the elements of psychic or moral treatment and they are invaluable in asylum as well as *in home treatment. They constitute nothing that* is new and they are the basis of the practice of general as well as asylum physicians.

Procedure.—In dealing with this aspect it has evidently been decided that the time has arrived when the person has to leave home and the case of the private patient alone needs consideration, for the procedure for the pauper lunatic is simple and the criminal lunatic is already in legal hands. The method for placing a private patient under legal care is one of two alternatives: either the *de lunatico inquirendo*, which is an inquisition held by one of the two Masters in Lunacy, before a jury, of whom 34 may be summoned by the sheriff, but not more than 24 are empanelled, and at least 12 of these must concur. Counsel for the petition must conduct the proceedings in a "judicial spirit," and no evidence of alleged insanity over two years previously must be tendered, the point being to keep to one or more of three special issues—viz., that at the time the person (1) is of unsound mi [illegible] or (3) is incapabl [illegible] lunatic may be [illegible] oath either in o[illegible] an inquisition are public. When a person has been found insane by inquisition he may traverse these findings—i.e., he may get the verdict set aside by proceedings determined in the Court of King's Bench or at the assizes, otherwise he remains a lunatic either until recovery, when the finding of the inquisition is put an end to by a *supersedeas* or is annulled by *his death.* When a lunatic is "*so found by* inquisition" a committee of the person and a committee of the estate are appointed, the one interested in his life and the other in the good management of, and possible succession to, his estate. The Masters in Lunacy hold all inquisitions and they make summary inquiries. *They may also make* consequential inquiries dealing with the person and property of any lunatic, should his property be of the value of £100 a year. If his property be of less value than £200, and if no relatives or friends will investigate, the inquiries are made by the county court judges, as also if the case be one of partnership and the assets are less than £500. Finally, inquiries may be made by the guardians of any union.

Section 116 of the Lunacy Act, 1890—the great practising section for lawyers—enables the Master in Lunacy, on a summons being taken out in his chambers and heard before him, to apply powers of management and administration of the estate in the case of (1) lunatics, not so found by inquisition; (2) every person lawfully detained within the jurisdiction of the English courts as a lunatic and not so found by inquisition; (3) in the case of insanity through mental infirmity arising from disease or old age; (4) in the case of persons insane, with an estate of not more than £2000, or yielding £100 a year; and (5) in criminal lunatics, continuing insane, and remaining under confinement. The other method of placing a private patient, or a patient not a pauper and not so found by inquisition, is through a "reception order" signed by a justice, upon petition of a near relative, and accompanied by two medical certificates. The order may, as already stated, be made summarily, without a petition; it may also be made by the Commissioners in Lunacy themselves, or in the case of a lunatic so found by inquisition the order may be made by the committee of person.

As to (1) the petition, (2) the order, and (3) the medical certificate. The petition must be signed by a relative of the patient if possible; if not, the reason why it is not so signed must be stated. The petitioner must not be related to, nor connected with, either of the medical certifiers and the petitioner must have seen the patient within 14 days of the presentation of the petition. The medical certificates imply an exceptional power granted by the State to members of our profession, in using which we deprive the subject of his personal liberty, his civil capacity, his social, financial, political, and even his domestic rights. Such a power is not given to any other functionary in the land; hence insanity becomes a very serious issue, and all the legal machinery from the justice of the peace to the Lord Chancellor himself may be set in motion. In stating that a person is mad it must be proved and it must be committed to writing. All the reasons must be given, a slip of the pen, an inaccuracy as to date, as to one's own registered qualification, or as to the residence of the patient will render the certificate invalid, and the whole process must be repeated. So particular are the Commissioners in Lunacy that they have even ordered the discharge of a patient on the ground that the certificate was invalid, for the reason that it did not contain the number of the house in which he lived. On another occasion the same thing happened because the medical men signed certificates, not from what they observed on any particular day, but from what was known to them in consequence of having attended the patient during a considerable period of time previous to certifying. A failure to comply with any of the legal requirements is fraught with an unusual amount of danger, for the law punishes severely when certificates are given improperly, whether through ignorance, inadvertence, or wrong intention. Indeed, any person thinking himself aggrieved may by the law of the land obtain, upon his discharge, copies of the documents upon which he was incarcerated, and may sue and prosecute the granter of the certificate, possibly involving his professional and financial ruin. Good faith and reasonable care must be proved by the certifier. With regard to the medical certificate, it holds good for seven days and one of the certificates must, if possible, be signed by the usual medical attendant of the patient and if not the reason must be given. The two medical men, who must not be related or partners, must see the patient separately and the examination, if the certificates are signed in England or Wales, must take place in England; similarly with respect to Scotland and Ireland. The certificates must be signed within seven days of the presentation of the petition. No medical man may certify his wife or his immediate relatives; neither may he be connected with, nor in any way interested in, the institution into which the patient is to be received. The certifier must write down facts observed by himself at the time of the examination, otherwise the certificate is invalid. Those relating to incoherence, violence, or refusal of food are generally evident. Such statements as great taciturnity, complete seclusion from society, aversion to cleanliness, or wandering about the streets at unreasonable hours are sufficient. A statement by the person that he, or she, is lost and is without hope of forgiveness, that he will be taken to prison and die a miserable death, that the devil whispers in his ear that he has committed the unpardonable sin, or the fact that he is violent in his conduct and unable to take care of himself, is ample and clear ground for certifying. It is well to avoid the use of conventional and vague terms such as "bad temper," "excitement," and "emotional" in the certificate. If the symptoms of insanity be obvious to the most obtuse layman this in itself is not a sufficient guarantee that the certificate is valid. The provisions of the statute must be fulfilled, not only in the spirit but also in the letter. If a false certificate be given the certifier is guilty of a misdemeanour and the greatest care should always be taken that the statements made are relevant, exact, and accurate.

The petition, together with the two medical certificates, should be presented to a magistrate "specially appointed" under the Lunacy Act or a county court judge, or a stipendiary magistrate. Either of these may sign the order for the person's detention, without necessarily seeing the patient who must be received into the specified place within seven days of the signing of the order. If the patient is received into an asylum or hospital—not having been seen by the magistrate—he is presented with a notice of his right to an interview with a justice, and the patient exercises his own choice, a magistrate being summoned if he so wishes. Any *magistrate not "specially appointed" can sign an order,* but in that case the order must be countersigned by a specially appointed magistrate within 14 days. A list of justices "specially appointed" may be obtained from the clerk to any petty sessional division, the police, or the clerk to a board of guardians.

If the case be urgent there is a more expeditious method than the above of getting a private patient under treatment into an asylum, and that is through an "urgency order." A relative if possible, if not, some person whose connexion with the patient is stated, and who has seen the patient within two days, may make an order for his detention. This order must be accompanied by one medical certificate. The certifier must have seen the patient within two days of signing the certificate, and must give his reasons for the urgency. The patient must be admitted to the specified asylum within two days of the signing of the order, and the order remains in force for seven days, within which time the ordinary petition, the magistrate's order, and the two medical certificates must be obtained.

Cost of maintenance.—Insanity is the most expensive illness with which any person can be afflicted. Home treatment involves costly nursing; this and the fees for medical attendance may easily amount to ten guineas per week, depending upon the acuteness of the case and the accommodation required. The plan of taking a special house is of necessity a more costly one still, and may amount to more than double that of home treatment, and the method of single care is very often quite as expensive. If the case be quiet and chronic such a person may be kept in "single care" at much less, and there are many so placed at about £100 a year. The registered hospitals and some of the larger licensed houses may take cases also at as low a rate as 25*s*. or 30*s*. per week, but oftener the charge is from two to six guineas, determined by the accommodation required and the nature of the case.

Conclusion.—To use a current phrase, "What do you think of it all now?" One may reply that as the result of a general survey of this question of insanity—a disease which, with the progressive complexity of our civilisation, is undoubtedly on the increase, and a disease which strikes more real terror into the heart of a family than does any other ill to which flesh is heir—it is not too much to state that the study of the laws which regulate the natural dependence and interaction of the various powers and affections of the human mind, demands more attention than it gets. In America the study of psychology is much more common among students of all kinds, even those who pursue purely commercial pursuits, than it is in this country.[3] This study enables us to read through the whole gamut of aspiration and desire, from the most sensuous to the most moral and spiritual of experiences. The study of the human mind has been the aim of the great poets, philosophers, historians, and seers of the world, and to its neglect are due most of the illusions, impostures, and superstitions of our day; evils which bring in their train misunderstandings, injustice, and most of the chronic discontentments of life. Let more encouragement be given to the study of the mind

in health and disease. We are called upon to treat mental diseases in living men and women. Pedantry about the neuraxon avails us little; the only method is to familiarise ourselves, firstly, with the healthy mind and, secondly, with departures from this, such as are seen in the diversified types presented to us among the inmates of our large asylums, where alone the necessary experience can be obtained, and by this method alone can we hope to afford relief to the saddest affliction which can befall humanity.

Claybury.

ON THE USE OF PURE CARBOLIC ACID IN THE TREATMENT OF SMALL-POX.

BY JAMES T. NEECH, M.D. DURH., D.P.H. VICT.,
MEDICAL OFFICER OF HEALTH OF HALIFAX, AND MEDICAL SUPERINTENDENT OF THE BOROUGH FEVER HOSPITALS, HALIFAX;

AND

J. F. HODGSON, M.D., CH.B. VICT.,
ASSISTANT MEDICAL OFFICER OF HEALTH OF HALIFAX.

SINCE the publication of "A Note on the Use of Carbolic Acid in the Treatment of Small-pox" by the former of us (J. T. N.) in THE LANCET of Feb. 21st, 1903, p. 518, ample opportunity has been afforded for further testing its efficacy in this disease. Briefly, the following are the results of our extended experience of this remedy. Altogether we have employed this method of treatment in 136 cases. Of this number five died, which gives a death-rate of 3·6 per cent. This compares very favourably with the results obtained in other parts of the country. The epidemic, though not so virulent as some, was, we think, by no means a mild one, as out of the 136 cases 22 were of the confluent type, 12 were semi confluent, and 103 were discrete. Of the latter 15, though discrete, were very severe cases. The patients on the whole were anything but efficiently vaccinated, so that the character of the disease and the modifying effects of vaccination did not materially contribute to this low mortality. The following table shows the number of cases, deaths, and percentage mortality under five and over five years of age.

—	*Unvaccinated.* Cases.	Deaths.	Mortality per cent.	*Vaccinated.* Cases.	Deaths.	Mortality per cent.
Under five years ...	8	3	37·5	—	—	—
Over „ „ ...	27	1	3·7	101	1	0 99
Totals	35	4	11·4	101	1	0·99

The three unvaccinated children who died were all suffering from severe confluent small-pox; one was a baby whose mother was suffering from small-pox when delivered The 27 unvaccinated cases above five years included some very severe ones, but *the only fatal* case was a chronic alcoholic who succumbed to heart failure following bronchopneumonia in the convalescent stage. Amongst the vaccinated the death was in a case of hæmorrhagic small-pox, which is *almost invariably fatal.*

The method adopted was that first mentioned—namely, to apply the pure liquid carbolic acid with a small camel's-hair brush to the vesicles over a certain area of the body each day, commencing with the face and head, until the whole of the vesicles had been touched. These applications were continued until the vesicles showed signs of drying up or of aborting. Some considerable time is required to do this as it should be done, carefully and thoroughly. Care must be taken also to avoid the acid running on to the healthy skin.

Although a careful watch was kept for the appearance of toxic symptoms carboluria was noticed in only two cases. Curiously enough, both belonged to one family, so that idiosyncrasy *might possibly have had something to do with* it, and it is quite possible that the acid may have been more freely applied than is usual or necessary in at least one of these cases. In some cases only one side of the patient was *painted with* carbolic acid and the other side was either left alone or treated with other local applications, such as carbolic acid with camphor, guaiacol in olive oil, or formalin. In all such cases it was plainly seen that carbolic acid gave the *best results. This was, we thought,* the simplest way to find out which drug applied locally gave the best results, especially as types of small-pox vary so in vaccinated persons. The application of the acid caused very slight and transitory pain and *relieved the intense irritation.* The patients never complained or scratched themselves. The effect appeared to be local, the pustules rapidly shrivelled and scabbed, and the further development of the papules and vesicles was either prevented or if not aborted comparatively little discharge resulted. In fact, all the vesicles had formed into scabs in from five to ten days after treatment, according to the severity of the cases, and in from ten to 18 days the scabs had fallen off, except of course those in the palms of the hands and the soles of the feet The ulceration of the skin in the pustular stage was practically prevented, so that dermatitis with cutaneous and subcutaneous œdema was lessened, and the tendency to the formation of scars was not nearly so great. The offensive odour from the eruption was entirely absent and to a certain extent the application kept the patients clean The absorption into the system of septic material from the pustules *is either* prevented altogether or is *only* very slight. This along with the lessening of the process of ulceration abolishes the secondary fever or renders it very mild The temperature generally kept at a low level after the appearance *of the pustular stage and* was *never much above* 102° F. even in confluent attacks in unvaccinated persons, and was normal long before it usually is in untreated cases. Delirium was very infrequent and the pulse was not markedly increased, as is usually the case when the pustular stage is reached. The risk of infection by aerial convection is also, we consider, much lessened, and we can discharge a patient with a greater feeling of safety a week or a fortnight before the usual time, as the treatment cuts short the disease to that extent at least. There was an entire absence of complications, such as multiple abscess, &c. The early removal of the scabs was effected by means of carbolic oil, bread poultices, but best of all by "antiphlogistin," which tended to prevent the formation of small superficial abscesses.

Halifax.

THE ETIOLOGY OF YELLOW FEVER.

BY JAMES B. TOMBLESON, M.B., B.CH. OXON.

SINCE writing the article which has already appeared in these pages[1] I have examined more cases and done other work which throws light on the subject and which I wish to record here. *For the purpose of making this record as short* as possible and at the same time comprehensive I shall divide it into the following heads: (1) a tabulated analysis of the more important points of 25 cases with a few remarks; (2) a record of the finding of the bacillus in infected mosquitoes and in their larvæ; and (3) a few remarks about the method of staining which a more extended experience *has shown to give* the best results, and one or two general statements which may be of interest.

It will be noticed that of the 25 cases in the accompanying table four were diagnosed by Dr. McPherson, port officer at *Salina Cruz; one was diagnosed* by Dr. Stubbs, the American consular agent at Coatzacoalcos. This I mention to show that I [illegible] by myself; more[illegible] my visits by Dr. R[illegible] who has lived here d[illegible] always agreed with my diagnosis in these cases. In every case I have found my bacillus present, without any exception, and from the urine in every case I have cultivated it almost always in pure culture, but in a few cases with an admixture of pus cocci or Finlay's micrococcus tetragenus. In Case 25 and in another which I have not included I found malarial parasites as well, often seeing parasites and bacilli together in the same corpuscle.

It will be seen from the table that I examined the liver

---

23	,, ,,	,,	99·6°	None.	,,	,,	,,	99·6°— 84 99·8°— 83	First.	,,
24	Sept. 2nd.	,,	103·4°	Large trace.	,,	,,	,,	103·4°— 92 101·6°— 68	Third.	,,
25	,, 3rd.	British.	104·5°	One-sixth.	,,	,,	Malarial.	104·0°—112 102·6°— 94	,,	,,

By *typical facies*, flushed, stupid-looking face, with injected conjunctivæ, is meant. By *typical tongue*, one furred but not very heavily with red edges and tip is meant. By *typical pains*, severe headache (frontal and occipital), severe pain in the back and the loins and in the whole muscular system are meant.

REMARKS.

CASE 1.—Icterus was present when first seen, with black vomit and motions. Bacilli were found in the blood and cultivated from the urine.

CASE 2.—Icterus showed itself in the conjunctivæ on the second day. Bacilli were found in the blood; no cultures were taken.

CASE 3.—Icterus was present in the conjunctivæ on the third day. Bacilli were found in the blood and cultivated from the urine.

CASE 4.—When first seen there was icterus over the whole body. Bacilli were found in the blood and urine. Black vomit occurred once.

CASE 5.—Icterus was present in the conjunctivæ on the third day. Black vomit occurred on the fifth and sixth day. Bacilli were cultivated from the urine; no blood was taken.

CASE 6.—Icterus was present when first seen as was also black vomit. Bacilli were cultivated from the urine; no blood was taken.

CASE 7.—Bacilli were found in, and cultivated from, the specimen.

CASE 8.—When first seen icterus was present and later spread over the whole body. Bacilli were found in the blood and cultivated from the urine.

CASE 9.—Icterus was present over the whole body. Black vomit occurred once. A relapse ensued. Bacilli were found in the blood and cultivated from the urine.

CASES 10 and 11.—Bacilli were found in, and cultivated from, both specimens.

CASE 12.—The patient was only seen in a relapse. Black and red blood was vomited. Icterus was present, especially after death. Bacilli were found in the blood and urine.

CASES 13 and 14.—Bacilli were demonstrated in both tissues from both patients.

CASE 15.—Icterus was present over the whole body. Bacilli were found in the blood and cultivated from the urine.

CASE 16.—Icterus was present in the conjunctivæ on the fourth day and later spread to the whole body. Bacilli were found in the blood and cultivated from the urine.

CASE 17.—Icterus was present in the conjunctivæ on the third day and later spread over the whole body. Black vomit occurred once. Bacilli were found in the blood and cultivated from the urine.

CASE 18.—When first seen icterus was present in the conjunctivæ. Bacilli were found in the blood.

CASE 19.—Icterus was present in the conjunctivæ on the third day and later spread to the whole body. Flaked vomit occurred once. Bacilli were found in the blood.

CASE 20.—Icterus was present in the conjunctivæ. Bacilli were found in the blood.

CASE 21.—Icterus, black vomit, and hiccough were present. The patient died from uræmia. Bacilli were found in the blood and cultivated from the urine.

CASE 22.—Icterus was present in the conjunctivæ on the third day. Bacilli were found in the blood.

CASE 23.—Bacilli were found in the blood.

CASE 24.—Icterus was present in the conjunctivæ and also over the whole body. Three coffee ground motions were passed. Bacilli were present in the blood and urine.

CASE 25.—Icterus was present over the whole body. Bacilli were found in the blood and cultivated from the urine.

and the kidney post mortem in two cases, sent by Dr. McPherson from Salina Cruz, and found the bacilli in all the specimens. In this connexion I think it worthy of notice that among my specimens prepared last year at the London School of Tropical Medicine I found two of yellow fever material; these I dismounted and decolourised, and then re-stained with toluidin blue, and in them demonstrated the presence of the bacilli in large numbers. As a check on my results I examined coincidently many cases of malaria and always failed to find the bacillus except in the two cases mentioned before in which malaria and yellow fever were coexistent.

Work on mosquitoes.—First I fed two mosquitoes on Case 9 in my series, killed them by putting them straight into form-alcohol (formalin 10 per cent. and alcohol 90 per cent.), imbedded them, and cut sections from one; in these the bacilli were so abundant that I at once sent section blocks straight off to London where they are now. Then I prepared a series of six in the same way, showing every stage from 24 hours after the ingestion of the blood to the time when it was completely digested. These were fed on Cases 22 and 24 and in all of them I found the bacillus in every stage of growth and sporulation. In some beautiful specimens I found the bacilli in the proboscis, evidently ready for injection into another individual. I then grew some larvæ in water containing urine from one of my yellow fever patients (I do not know whether or not the parent was infected), and imbedded and cut them, and in these also I found the bacilli in all stages of growth. I then tried to get some infected mosquitoes to breed in clean water in my cage, but they refused to lay eggs, and so this experiment failed.

After this for two or three weeks circumstances prevented me from doing anything further, and then the norther season began, and at the same time the disease disappeared, and so for further work I must wait till next year.

Method of staining.—The best results which I have obtained have been secured by staining with a carbo-toluidin blue prepared as follows. To a 5 per cent. solution of carbolic acid I add enough saturated solution of toluidin blue in absolute alcohol to make the mixture of a deep blue colour; I stain with this for three hours, dry by heat (I always put the slides for ten minutes in the incubator) without any dehydration with alcohol, clear with xylol, and mount. This refers, of course, to sections; in the case of blood slides naturally no dehydration or clearing is needed. The colour fades out of the bacilli very quickly, much sooner than out of the tissues.

Before closing this little notice I should like to call attention to one point in the treatment of the disease. I always make a practice of using large injections of warm water into the large bowel from the beginning of the third day of the disease to the end. I inject two quarts twice daily, taking half an hour or more over the operation, so as not to distress the patient, and have found it always most beneficial; in fact, I believe that if this course were always followed secondary fever would entirely disappear and the disease would lose much of its terrors.

Rincon Antonio, Istmo de Tehuantepec.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

A CASE OF IMPLANTATION OF THE DIVIDED THORACIC DUCT INTO THE INTERNAL JUGULAR VEIN; RECOVERY.

(Under the care of Mr. E. DEANESLY.)

FOR the notes of the case we are indebted to Dr. G. Wright, house surgeon.

A woman, aged 34 years, was admitted into the Wolverhampton and Staffordshire General Hospital on Sept. 24th, 1903, for the removal of tuberculous glands from the left side of the [illegible] ay in the anteri[illegible] jaw and from [illegible] ting and deeply adherent, extended along the carotid sheath for its whole length and also beneath the sterno-mastoid into the posterior triangle. The lowest gland, of the size of a walnut, lay behind the clavicle immediately over the junction of the jugular with the innominate vein. The upper part of the anterior triangle was cleared of glands through an oblique curved incision in the fold of the neck, the jugular vein being exposed and cleaned. A second incision parallel to the first was made over the posterior triangle a short distance above the clavicle and the remaining chain of glands was dissected out. During the removal of the lowest gland a small hole was made in the internal jugular vein close to its junction with the innominate. It was found impossible to close this securely without dividing and ligaturing the jugular vein itself. As an additional precaution the jugular vein was also ligatured again in the anterior triangle where it was already exposed. Copious escape of milky chyle now led to a search for the thoracic duct which was found to be completely divided close to its termination. Owing to the natural curve in the duct, which arches upwards for some distance and then descends to its junction with the great veins, it was easy to free it in an upward direction and to dissect it out for over an inch. The divided end could then be brought up to the internal jugular vein above the ligature on the latter without tension on the duct. As the internal jugular vein had also been ligatured at a higher point in its course, near the corner of the hyoid, it was necessary to demonstrate that the portion of the vein lying between the two ligatures possessed collateral circulation, as it presumably did through the thyroid veins. This fact having been proved by puncturing the vein and noting free hæmorrhage and refilling of the vein the divided end of the thoracic duct was implanted into the punctured opening in the vein by two sutures of the finest silk in such a manner that about one-eighth of an inch of the duct projected within the lumen of the vein. Hæmorrhage during the implantation was controlled by a lightly applied clamp immediately above the punctured opening. The sutures were passed through all the coats of both vein and duct in such a manner as to avoid occluding the opening in the duct. As the latter was of the size of a large goose quill this was satisfactorily accomplished and on removing the clamp from the vein no further hæmorrhage occurred. The wound was [illegible] was inserted.

[illegible] s after the operation, there [illegible] discharge but there was no [illegible] this consisted of chyle or not. It seemed, however, larger in amount than the ordinary wound serum. On the second day the discharge had not saturated the dressing and from that day there was no suspicion whatever of discharge of chyle. The upper wound healed by primary union; healing of the lower wound was slightly delayed by superficial suppuration, but the patient returned home with both wounds completely healed 18 days after the operation. No untoward symptoms of any kind occurred, either during convalescence or subsequently, and the patient remained in good health when seen two months after the operation.

Remarks by Mr. DEANESLY.—I am not aware that the method of dealing with a divided thoracic duct adopted by me in this case has been adopted before though it has some obvious advantages where it can be carried out. The older text-books of surgery considerably exaggerated the seriousness of division of the thoracic duct which in an edition of a well known work dated 1887 is briefly described as a fatal injury. Death was said to occur either from escape of chyle into the mediastinum or from the exhausting effects of the continual escape of chyle through a fistulous opening in the neck. Later experience entirely refutes these statements and it is probable that death in the earlier recorded cases was due to septic infection of the neck and mediastinum and not to the injury of the duct itself. With regard to the possible formation of a chronic fistula and the effects of such a condition on the nutrition of the body, I know of no case recorded in which such a fistula existed for a sufficient length of time uncomplicated by septic wound conditions to arrive at any conclusion. But from modern clinical experience it is improbable that a permanent fistula will ever occur. Treves in his "Surgical Anatomy" states that the thoracic duct has been cut and tied without ill result and Kocher reports the same fact on his own authority in his "Operative

Surgery." Allen and Briggs, in *American Medicine* of Sept. 14th, 1901, report 15 cases of injury of the duct during operation with 14 recoveries. In what proportion of these the duct was completely divided I do not know. I am informed also by Professor Starling that he has invariably failed in attempts to establish a permanent fistula of the thoracic duct in dogs, even when the opposite duct has also been ligatured; indeed, in dogs the collateral circulation in the lymph channels is so free that, according to Professor Starling, simultaneous ligature of both the right and left thoracic ducts in the neck produces only a temporary obstruction and no permanent ill effects. Taking these facts into consideration it is probable that ligature of the divided duct is the simplest procedure in cases of accidental injury. As implantation of the duct into the vein seemed to me, however, at the time a procedure more in accordance with physiological ideas it is perhaps worth recording as an alternative method where practicable.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Leukæmia.—Exhibition of Specimens.

A MEETING of this section was held on Dec. 14th, Dr. H. O. EARL, the President, being in the chair.

Dr. T. G MOORHEAD read a preliminary account of some investigations which he had been making into the etiology of Leukæmia. He said that he had prepared a series of extracts from glands obtained post mortem from a case of lymphatic leukæmia and claimed to have produced leukæmic changes in rabbits by the injection of one of these (sterilised) extracts. The changes found consisted in enlargement of the spleen and of several groups of lymph glands and in the red marrow excessive development of nucleated red blood corpuscles. Quantitative and qualitative changes were also observed in the white cells of the blood. Injections of a similar extract prepared from normal human lymph glands did not produce any change in the hæmopoietic tissues of rabbits. The extract from the morbid glands caused a pronounced fall in blood pressure while the similar extract from normal glands had no such effect.—Professor E. J. MCWEENEY asked whether Dr. Moorhead had used glands from myelogenic or lymphatic leukæmia and said that inasmuch as their pathology was different this was a matter of much importance —Professor J. A. SCOTT said that he was so far from thinking that the various forms of leukæmia were different that, on the contrary, he believed that the principle of cellular intoxication might fairly be extended from the lymphatic lesions to other cellular conditions, such as sarcoma or cancer, which were also associated with blood changes.

Dr. W. S. HAUGHTON showed a Rectum, Pelvic Colon, and part of Iliac Colon removed for carcinoma recti by the double method of laparotomy and transacral incision six weeks previously. The patient was going on well. The tumour was a typical adeno-carcinoma of the rectum extending around the lumen of the bowel for more than three inches in length, without infiltration of the perirectal tissues or glands.

Dr. ALFRED R. PARSONS showed specimens removed from a man, aged 20 years, who was admitted to the Royal City of Dublin Hospital on Sept. 23rd suffering from Jacksonian Epilepsy. The patient, who had been previously in good health with the exception of a chronic cough, was suddenly seized with a convulsion and was carried into hospital during the attack. The lower half of the left side of his face and the left arm from the elbow downwards were paralysed. He had, however, no loss of power in his left leg but the reflexes were exaggerated. The paralysis gradually increased till he had complete left hemiplegia with greatly increased deep reflexes. There was bronchiectasis in the lower lobe of the left lung. As there was no ear disease present a diagnosis of intracranial abscess near the Rolandic area secondary to chronic pulmonary suppuration was made and Mr. G. J. Johnston trephined the patient over the arm centre but found no pus. At the necropsy the lower lobe of the left lung was found to consist of numerous bronchiectatic cavities filled with pus and in the brain there was a large abscess filled with greenish pus lying directly underneath the arm centre not more than half an inch from the cortex. The needle used in exploring must have entered the abscess cavity but before doing so had probably become plugged with brain tissue.

Dr. J. T. WIGHAM showed a Cancer of the Breast and Various Internal Organs secondarily affected, with sections. The cancer was of the ordinary type of scirrhus and was well marked, the interest in the case lying in the route by which the disease had spread to the internal organs. Cancer nodules could be discovered in the liver and under the pleura, the pericardium, and the endocardium, and sections showed the growth pushing through the heart fibres between the two last. Similar growths were also found in both ovaries and along the course of the Fallopian tubes, while the peritoneum was quite free and no other cancer masses were discovered below the level of the liver.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 4th, Dr. Seymour Taylor, the President, being in the chair.—Mr. F. G Lloyd read a paper on Appendicitis. In dealing with the treatment of the affection Mr. Lloyd expressed a leaning towards conservatism and stated the conditions calling for surgical interference together with the methods of procedure which he had found most useful.—The discussion on this paper was postponed to a future meeting of the society.—Dr. Alexander Morison read a paper on Boldness in the Treatment of Heart Disease. The cases to which attention was specially directed were those instances of grave cardiac failure occurring in young adults or in those in the prime of life in whom there was no evidence of vascular degeneration and whose reserve force was commensurate with their development. In these tincture of digitalis or the combined tinctures of digitalis and strophanthus were recommended in doses of 15, 20, 25, or 30 minims at intervals of four hours until a definite effect was produced upon the action, force, and capacity of the dilated and failing heart. This might require the continuous administration of the drug until 200 or 300 minims had been taken. Before beginning this method of treatment, however, it was necessary to prepare the patient in certain particulars for the action of the remedy. The surcharged venous system should be relieved in suitable cases by venesection (which Dr. Morison preferred to leeching) to four or ten ounces, the anasarcous limbs drained by Southey's tubes or by incision, and fluid effusion in the chest or abdomen removed as far as possible. With the assistance of good nurses the method might be efficiently carried out in the patient's own home. That there was a certain element of risk in this rapid method of obtaining cardiac control was admitted, but provided that only suitable cases were selected and sufficient skilled supervision and control were exercised this risk was by no means great.—Dr. Lilienstein (Bad Nauheim) expressed agreement with the views of Dr. Morison as they were in accord with his own observation and experience. At the same time he deprecated the use of digitalis and its congeners in cases in which the action of the drug was not called for. A careful consideration of the conditions of the individual case was important in all instances of disorder of the heart, and this held good not only in the matter of medicines but also with reference to physical therapeutics. The use of the carbonic acid bath was an instance in point and harm might easily be done to patients who were not carefully watched. He attached great importance to sparing the heart and was in the habit of interposing after the second, third, or fourth day of bathing a bath-free day. Dr. Lilienstein also referred to the importance of mechanical treatment of heart cases (such as massage and active and passive gymnastics). He agreed with Dr. Morison's remarks as to the value of blood letting in suitable cases.—The President considered that the tendency of modern medicine in the treatment of cardiac failure was summed up in the word "boldness." Probably had those methods of treatment which had been so ably advocated by Dr. Morison been suggested in the immediately preceding generation of practitioners they would have been received with opposition if not with ridicule. But modern clinical experience was altering their views of treatment. In the great majority of cases of heart failure not only was there a want of balance between the two sides or between two cavities of the heart but there were results of this, and so far as he was able to read the phenomena of heart failure congestions of various organs and parts constituted *in great measure the enemy* which had to be attacked. Therefore he resorted to venesection in many instances and to leeching frequently, but trusted more to the former than to the latter method. Nor did h[illegible] which sleep afforded in these case[illegible] *opium or morphia* providing the [illegible]organic disease. There was, however, no "golden rule" in the treatment of such cases and the peculiarities and idiosyncrasies of the individual had to be taken into account as well as the visceral malady *in formulating any line of treatment.*—Mr. R. W. Lloyd, referring to an allusion to the work of the anæsthetist in Dr. Morison's paper, pointed out that there were differences between the methods of the physician and the anæsthetist in the matter of heart control.—Dr. Neville T. Wood agreed with Dr. Morison that in a limited number of cases large doses of digitalis after suitable preparation of the patient would produce results that might be fairly described as startling but in another class of case equally extraordinary results could be obtained by the use of almost infinitesimal doses. He, therefore, preferred to advocate precision rather than boldness in cardiac therapeutics.—Mr. W. P. Mallam *quoted a case of aortic regurgitation accompanied by extreme* cardiac pain and distress in which complete relief followed blood-letting to the extent of eight ounces.—Dr. Morison replied.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—*A meeting of this society was held on Dec. 10th,* when Mr. E. W. Roughton opened a discussion on the Hygiene of the Mouth. In the course of his introductory remarks Mr. Roughton referred to the power of the mouth to produce disease in other parts of the body being due to its acting as a hotbed of bacterial growth. In cases of extensive caries and of well-marked pyorrhœa alveolaris the number of the mouth bacteria was enormously increased. It was also probable that their virulence was enhanced and that the general health of the patient being deteriorated the power of resistance to bacterial invasion was diminished. The functions of the digestive tract were materially influenced by the condition of the mouth. When the latter was clean and well cared for the bacteria of the intestines were almost entirely (about 97 per cent.) derived from food and drink, but in persons with neglected mouths as many as 30 per cent. of the bacteria present *in the fæces must be regarded as derived* from the mouth itself. Not only might the bacteria of the mouth set up fermentation of the stomach contents but they might actually attack the wall of the stomach, producing different forms of gastritis. Evidence seemed to point to the mouth as the source of infection in many obscure cases of blood poisoning, using the term in its widest sense. Malignant endocarditis, infective osteomyelitis, septicæmia, and obscure febrile conditions had all been attributed with good reason to infection from the mouth. The intimate connexion between tonsillitis and acute rheumatism was shown by the frequency with which the former preceded or accompanied an attack of the latter. Chronic joint diseases were often associated with oral sepsis and they were sometimes benefited by improving the condition of the mouth. The mouth was also a *means of transmitting disease from person to person.* Diphtheria bacilli were sometimes found in the healthy mouth and it was common for virulent organisms to remain in the mouth and throat for weeks after a patient had apparently completely recovered from an attack of diphtheria. Operations in unclean mouths were attended with risk to the operator. Many cases of local and general septic infections had occurred in this way. Syphilis had often been transmitted by the saliva of an infected person. The treatment of carious teeth must of necessity be almost entirely in the hands of the dentist but the prevention of caries should come within *the sphere of every medical* man. General hygienic measures, avoidance of excess of carbohydrate food, especially bread and potatoes, and thorough mechanical cleansing of the teeth should be urged more cogently than most medical men were in the habit of doing at present. Children's temporary teeth should not be allowed to fall into a state of neglected decay. Only by periodical inspection could freedom from caries be insured. Acids introduced into the mouth as medicines or with the food had a deleterious effect on the teeth; the mouth should therefore be well rinsed after taking such medicines. The reaction of mouth washes should be neutral or slightly alkaline. In febrile [illegible]ed by the nurse; this [illegible] would hasten his con[illegible]d. In investigating a case of dyspepsia the physician should not omit to examine the mouth and should insist that dental insufficiency or abnormal oral sepsis should be adequately treated. Before performing operations on the mouth or jaws *carious teeth* should be filled *and stumps extracted and the parts made as* aseptic as possible by the use of a suitable antiseptic mouth wash.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Dec. 17th, Mr. Rushton Parker, the President, being in the chair.—Mr. W. Thelwall Thomas exhibited Receptacles for Dressings designed by him to facilitate the carrying out of aseptic surgery in private practice. *The boxes are rectangular, the lid being placed under*neath and let in in such a way that when the box rests on a *flattened surface dust cannot enter; the sides have perforated* "hit and-miss" slides. They fit into a large steam steriliser and each box will hold the necessary dressings, bandages, *sheets of sterilisable waterproof material covered with thick* muslin, and two specially designed gowns. A dark mackintosh cloth case fits over the box.—The President said that the boxes shown were by far the most convenient and suitable ones he had seen.—Dr. A. Gordon *Gullan showed a lad, aged 18 years, suffering from Morbus* Cœruleus. He was able to follow his trade as a watchmaker. There were signs of enlargement of the right heart with obstruction of the pulmonary artery and probably a patent ductus arteriosus.—Dr. Gullan also reported two cases of *Cretinism in youths 20 years of age, one patient being* shown. Both were typical cases. One was improving under thyroid and the other had shown no improvement.—Dr. *Hubert Armstrong referred to the risk of Sudden Death in* Congenital Heart Disease, and mentioned two cases in *his own experience, one a baby and the other a boy,* aged 12 years.—Mr. A. Nimmo Walker showed a woman, aged 49 years, with Double Optic Atrophy and Double Third Nerve Paralysis. There was a history of "inflammation of the bowels" two years previously, with vomiting and headache, and the lesions were probably due to a basal syphilitic meningitis implicating the affected nerves in the interpeduncular space and the chiasma. Mr. Walker said it was a rare case and had only occurred once in 9000 patients seen at St. Paul's Eye and Ear Hospital *in the present year.* Some power was returning under mercurial inunction and iodide of potassium internally.—Mr. George G. Hamilton read a paper on Rapid Paraplegia and reported a case which will be published in full later. In commenting upon the case he thought discussion might usefully turn upon the following conditions: traumatic neurasthenia, meningitis, spinal hæmorrhage, Landry's paralysis, peripheral neuritis, and toxic palsies. In this particular case the post mortem examination revealed a hæmorrhagic myelitis.—Dr. E. E. Glynn had examined the spinal cord and cerebro spinal fluid and had found no evidence of bacterial infection.—Dr. W. B. Warrington said that many cases of so called acute myelitis were really due to softening of the cord following syphilitic arterial disease but the differential diagnosis was difficult. He suggested that a *syphilitic history, the spread of the symptoms from* one limb to the other, with the Brown Séquard features, might help and quoted two cases in which this symptom-complex was present. Primary hæmorrhage into the cord was extremely rare. It was important to recognise a syphilitic origin for its guide to treatment.—Dr. T. R. Glynn, Dr. Nathan Raw, Dr. W. Carter, and Dr. J. Barr spoke and Mr. Hamilton replied.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 10th, Dr. Heywood Smith, *the President, being in the chair.*—Dr. H. Macnaughton-Jones showed a Modification of Bossi's Instrument for dilating the Cervix much less cumbersome and much easier to work than the original model which, in 1901, he had been the first to use in this country. Since that time many cases of labour had been successfully and expeditiously concluded by the aid of that instrument and he believed that the lacerations which had in some cases followed its use on the continent and in America were to be attributed to want of caution in its application or to too rapid dilatation.—Dr. H. Macnaughton-Jones, jun., said he had used the instrument shown to induce labour at the eighth month in a tertipara with a large fibroid and found it most satisfactory —Dr. Macnaughton-Jones, sen., also showed Various Specimens with the aid of the epidiascope.—Dr. Bedford Fenwick read a paper upon the Treatment of Stenosis of the Cervix, especially in regard to that congenital form found with a conical portio and a pinhole os, and generally associated with dysmenorrhœa and sterility. After division of the cervix on each side for about half its length with scissors his method was to draw the flap formed by the anterior lip together, longitudinally, with temporary sutures and to leave the posterior lip flat and open ; direct union of the surfaces of the wounds was thus prevented, they became covered with mucous membrane so that they did not afterwards adhere, and the patency of the canal was maintained. In 87 cases in which he had practised this operation it had invariably given relief and from subsequent investigation he had reason to believe that in 91 per cent. of these cases the relief had been complete and permanent. Moreover, the method had been equally successful in the hands of others who had adopted it after seeing him apply it at the Hospital for Women, Soho.—In the discussion Dr. C. H. F. Routh and Dr. G. R. Hodgson concurred in recommending the use of a stem pessary instead of operation, and Dr. Macnaughton-Jones and the President in preferring division of the isthmus with Sims's knife followed by dilatation.—Dr. Fenwick briefly replied.

Glasgow Pathological and Clinical Society.—The third meeting of the session of this society took place on Dec. 14th, Professor R Muir, the Vice-President, being in the chair.—Dr. John Anderson showed the organs from a case of supposed Splenic Anæmia.—Professor Muir exhibited a Liver containing very large Carcinomatous Tumours secondary to an adeno-carcinoma of the sigmoid flexure. The patient was only 26 years of age and the disease ran its course in three months ; there was no jaundice. The weight of the liver was 14 pounds.—Dr. J. Barlow showed a specimen of Enteric Intussusception successfully treated by resection of the bowel and read a short account of the case. The *intussusception was very tightly strangled ; it contained* fully 15 inches of intestine.—Mr. R. H. Parry showed (1) a Tumour of the Prostate removed by Freyer's method ; and (2) a large Fæcal Concretion which was lodged in the cæcum and which necessitated excision of the cæcum. The symptoms pointed to malignant disease in the cæcal region but microscopical examination of the specimen showed nothing of this nature. The operation was successful.—Dr. J. Lindsay Steven and Dr. C. Workman described the clinical features of, and showed the heart from, a case of sudden death caused by Embolism of the Main Trunk of the Left Coronary Artery.—Dr. Carstairs C. Douglas communicated a short note on the Ortol Reaction for Milk and demonstrated the test. It enabled a distinction to be made readily between fresh milk and milk which had been pasteurised at too high a temperature. The fresh milk gave a brick-red reaction on the addition of ortol and peroxide of hydrogen, while the sterilised or boiled milk remained colourless. The importance of this in relation to infantile scurvy was discussed.

Æsculapian Society.—A meeting of this society was held on Dec. 18th, Dr. Leslie Durno, the President, being in the chair.—Mr. F. Hewitt Oliver showed a boy, aged 11 years. At the lower end of the left radial diaphysis was a swelling of bony hardness and ridged, neither tender nor painful. The enlargement was of about two radial diameters. There was a slow increase of size from its reappearance six months ago as of a similar but smooth swelling of the proximal phalangeal shaft of the left index. Both of these growths had been removed three and three-quarter years ago. The left forearm was about one inch shorter than its fellow.—Dr. B. G. Morison related a case of a woman whose labour began naturally at the eighth month. The placenta was attached to the margin of the internal os uteri and the child presented transversely. The placenta was separated by the hand under chloroform and forceps were applied to the vertex. The child was born dead and peeling. About half an hour after delivery and soon after removing the hand from over the uterus a moderate-sized clot was passed and the patient nearly collapsed. Saline enemata were given and followed by uterine irrigation with a solution of fluid extract of suprarenal gland (one drachm to the pint). Good uterine contraction immediately followed the irrigation and no more hæmorrhage occurred. Pyrexia began on the evening of delivery and on the third day left basic pneumonia was diagnosed, from which the patient recovered on the fourteenth day.

Bristol Medico-Chirurgical Society.—An ordinary meeting of this society was held in the Medical Library of University College, Bristol, on Dec. 9th, Mr. J. Paul Bush, the President, being in the chair.—Mr. T. J. Tonkin (introduced by Mr. F. Richardson Cross) read a paper on Leprosy in Jamaica, illustrated by lantern slides.—The President, Dr. Fisher, Dr. J. Michell Clarke, Dr. C. Steele, Dr. Cave, and Dr. Alexander joined in the discussion which followed.—Mr. Munro Smith showed a specimen and some lantern slides from a case of Gastro-jejunostomy.—The President, Mr. F. Lace, and Dr. E. W. H. Groves remarked on the case.—Mr. Lace read short notes of a case of Intestinal Obstruction due to a hair ball and showed the specimen.—The President, Dr. Alexander, and Dr. Groves spoke on the case.

Reviews and Notices of Books

Hydrologie. Par HENRI CAUSSE, Chargé du Cours d'Hydrologie à la Faculté de Médecine et de Pharmacie de Lyon. Paris: F. R. de Rudeval. 1903. Pp. v.–317. Price 5 francs.

THERE are already in existence a very large number of books on potable waters, on water analyses, and on mineral waters, and it might *primâ facie* appear that another volume on these subjects was not required. The recent progress made, especially in the fields of bacteriology and in the chemistry of the organisms contained in water, has, however, made it possible that an entirely new book devoted in great part to these aspects of the subject would fill a gap which remained vacant in the literature of the subject. It frequently happens in the case of any science which has undergone rapid development that an entirely new work is best fitted to treat the new situation, whereas in the case of a subject of which we have a more complete and certain basis of knowledge the same book may go on from generation to generation. For instance, Gray's Anatomy survives.

Dr. Causse's work is divided into five parts. The first is an introductory disquisition on potable water and teaches the effects of the soil on its composition, showing how it comes about that the chemical composition of the water varies as a result of its passage through the earth. The second part deals with the methods of chemical analyses and with the interpretation which should be put on the results of the analyses. The third part is devoted to the bacteriology of the subject, including the methods in use for the artificial cultivation on gelatin of the more common of the pathogenic microbes found in water. In the fourth part the author first describes the various effects of different waters on certain reagents which yield results to be estimated by changes produced in their colour, and the interpretation of these changes, and in the second place he treats of the different contaminations which are liable to affect potable water. The fifth division of the book is devoted to a description of mineral waters and to the special methods adopted for their analysis. To the English reader we would specially commend this chapter. The book is well written, clearly illustrated, and provided with a good index.

The Exact Science of Health based upon Life's Great Law. By ROBERT WALTER, M D Vol. I., Principles. London: Kegan Paul, Trench, Trübner, and Co., Limited. Pp. 302. Price 10*s.* 6*d.*

THIS work is said to be "really an argument based on facts." But they are "facts of demonstration rather than of observation." The author feels that he has incurred a grave responsibility in making the claims which he does, but his are "not the vapourings of a novice" but rather the product of nearly 50 years of earnest study which has culminated in the "development and verification" of "Life's Great Law." There is, it would appear, a trinity of fundamental laws, the discovery of each of which in turn has revolutionised the world of science. Gravitation, the author tells us, gave us a trustworthy astronomy, chemical affinity gave us chemistry, while Life's Great Law yields a correspondingly trustworthy vital science. He proceeds to enunciate the great law and the present volume is occupied chiefly in an examination of the exact science of health and the principles upon which the knowledge is founded. A second volume is promised and this is to deal with the practice founded on the principles here stated. A brief foretaste is given of the manner in which the principles are to be applied and those who dislike the dry details of clinical observations and the toilsome investigations of the laboratory may possibly care to study the unfettered *ipse dixits* of the author who gives his views on the treatment of diphtheria and pneumonia with a confidence which may excite admiration. It is, however, unlikely that his teaching will cause amongst English physicians the imitation which is the sincerest form of flattery.

It was formerly the practice amongst the reviewers of novels not to destroy any possible interest there might be in their plots by fully revealing them to the public. We have the like feeling in the case of the author of this work and must therefore refer the curious reader to the book itself for a full enunciation of Life's Great Law which he will readily find set out in bold type. It should, however, in fairness be added that we do not think the secret worth the price asked for the book—and when applied in practice, as suggested by the author, it is subversive of all faith in the most striking developments of modern practice.

LIBRARY TABLE.

The Study of Tropical Diseases in Dutch India.—The second part of the forty-first volume of the *Genees kundige Tijdschrift voor Nederlandsch-Indië* contains a synopsis of the course that is to be followed at the institution for the study of tropical diseases which has been established in Weltevreden, Java. Similar institutions have been organised at various places in Europe but the Dutch medical authorities are of opinion that better opportunities for the attainment of the end in view are to be met with in tropical regions than can possibly be forthcoming within the temperate zone. In the first place the diseases in question can be investigated during their acute stages, and, secondly, their mode of origin can be scrutinised in their own home. There is also scope for original research in the well-known fact that some affections with which European medical men are familiar frequently follow a distinct course under the influence of an eastern sun. The director of the laboratory at Weltevreden is Dr. J. de Haan. Dr. G. Grijns is the sub director and Dr. G. W. Kiewiet de Jonge is the professor of tropical medicine. The duration of a course is three months. The curriculum comprises: (1) clinical lectures on tropical diseases; (2) tropical hygiene, acclimatisation, water, habitations, conservancy, and climatology; and (3) clinical lectures and demonstrations on bacteriology.

Atlas und Grundriss der gesammten Augenheilkunde. (*Atlas with a Short Account of Ophthalmic Diseases*) In Three Volumes. Vol. II., Ophthalmoscopy and Ophthalmoscopic Diagnosis. With 149 Coloured Plates and Seven Uncoloured. By Professor Dr. O. HAAB. Fourth edition. Munich: J. F. Lohmann. 1904. Pp 82. Price 10*s.*—This volume is one of Messrs. Lehmann's hand atlases of which about 40 have been published and which are marvels of cheapness and excellence. They are of convenient size, printed upon good paper, and supply trustworthy illustrations to works on almost every branch of medical knowledge. Thus three volumes are assigned to gynæcology, two to pathology, three to ophthalmology, and others to diseases of the skin, the mouth, the larynx, the ear, the nervous system, the bones, and to the wider subjects of histology and anatomy. Each volume has an essay prefixed to the plates which contains a brief exposition of the subject to which the volumes are devoted. The plates themselves in the present atlas, although not in the highest style of chromolithography, are not coarse, have been carefully selected, and are consequently representative and form collectively a very useful adjunct to any treatise on the diseases of the eye. They would be more useful to English readers if the introduction and the legends of the plates had been translated into English.

Looking Back.

FROM

THE LANCET, SATURDAY, DEC. 24, 1825.

ON THE STRUCTURE AND FUNCTIONS OF THE SPLEEN.

BY SIR A. COOPER

The following is an abstract[1] of Sir A Cooper's opinions on the structure and use of the spleen; which were delivered by him to the anatomical class a few days since, in a lecture upon that viscus

The most curious part of the structure of the spleen, he observed, was in the veins, and here Sir A. exhibited to the class the spleen of an ox and also of a calf, in which the distribution and commencement of the veins were well seen. He compared the internal structure of these preparations with a dried preparation of a turtle's lung, and said, that the similarity was so great, that the lung had been then placed upon the table, by mistake, for a preparation of the spleen. The cells of the spleen Sir Astley remarked were formed by the splenic vein, into which the blood is poured from the minute capillary branches of the splenic artery. In order to illustrate the elasticity of the membrane, or proper capsule of the spleen, Sir Astley introduced a pipe into the splenic vein and then inflated the spleen; it readily admitted of distension, and its size was much increased, but it was immediately emptied by its own elasticity. By means of an injecting syringe, Sir Astley threw water into the veins of a spleen, upon withdrawing the syringe, and holding the viscus in the hand, it was seen to empty itself and resume its original size. The spleen upon which this experiment was shown appeared very small, but it held twenty-four ounces of fluid. "These were my play-things, gentlemen, (said the worthy Baronet, with a good-natured smile,) when I was ill in the country last summer, and I will tell you the result of these investigations, or rather, the conclusion to which I have arrived respecting the use of the spleen; and it is this—*The spleen is an elastic reservoir and manufactory of venous blood.*"

Sir A. said the blood was conveyed into cells formed by the splenic vein, and was there retained until a supply of dark blood is demanded for the liver, when, by the elasticity of the investing membrane of the spleen, its contents are propelled. The blood in the splenic veins becomes additionally charged with carbon and forms dark blood, which is necessary to the formation of bile. Sir A. remarked,
was this,—
its carbon,
uantity. In the spleen of the reptile class, and also in birds, he observed, there were vessels in lieu of cells, and it is only in quadrupeds that the cells can be ascertained.

Sir Astley Cooper next alluded to the hypothesis of Dr. Haighton upon the use of the spleen, which was, that when the stomach was full, it pressed upon the spleen, and thus impeding the circulation through that viscus, the blood was more copiously propelled to the arteries of the stomach, in order that a large quantity of gastric juice might be secreted. Sir A. said if such were the use of the spleen to the stomach, it must also serve for a similar purpose to the pancreas; but he admitted, that it remained for further investigation to prove, what other offices the spleen performed, in addition to that which he conceived to be its principal use.

THE LANCET.

LONDON: SATURDAY, DECEMBER 26, 1903.

THE ANNUS MEDICUS 1903.

MEDICINE AND THERAPEUTICS.

Tuberculosis.

THE subject of tuberculosis, more particularly the pulmonary variety, has attracted considerable attention during the past year. The interest taken in the subject by HIS MAJESTY the KING has doubtless given zest to the efforts which are being made to combat the spread of the disease and to perfect its treatment. The steps which have been taken in connexion with the KING EDWARD VII. Sanatorium are familiar to our readers. In THE LANCET of Jan. 3rd we published in our columns the three prize essays and plans. A site was acquired at Lord's Common, Easebourne, about three miles from Midhurst, and the KING laid the foundation-stone on Nov. 3rd. The site is eminently suited for the purpose. The soil is the lower greensand of the lower cretaceous series which is admirable for surface drainage and for residential purposes. The climate of the district is mild and equable and meteorological observations record a plentiful amount of sunlight. The design of the sanatorium has been determined on the best examples of similar institutions in this country, in Germany, and in Switzerland. The primary object of the sanatorium was to provide for sufferers from pulmonary tuberculosis belonging to a class above the very poor—teachers, governesses, and members of other ill-paid professions; also for clerks, shop attendants, and the like, for whom no provision in sickness of this kind exists. But since the sanatorium was intended to be the best which could be constructed the KING did not think it right that those members of the community who could afford to pay for good accommodation and skilful treatment should be entirely excluded from the benefit of the institution; therefore certain rooms will be set aside for patients who can afford higher fees.

The question of the infectivity of pulmonary tuberculosis has again been brought prominently before the medical profession by various observers. Dr. H. TIMBRELL BULSTRODE, in delivering the Milroy lectures of the Royal College of Physicians of London, pointed out that at the present time there may be said to be two schools of thought with regard to the main channels of infection between man and man, the one school maintaining that the greatest danger is to be attributed to the tubercle bacillus contained in the dried sputum, whilst the other considers that there is more potency for harm in the droplets thrown off by a tuberculous patient during coughing. His remarks were characterised by great moderation, and although admitting that in certain circumstances pulmonary tuberculosis is infectious, he held that the communicability of the disease can only be contrasted, not compared, with that of diseases such as small-pox, typhus fever, and whooping-cough.

The address which was delivered by Professor BEHRING at the recent Congress of German Naturalists and Medical Men also contained much valuable information. He expressed the opinion that the communication of pulmonary tuberculosis to adults by contagion has not yet been demonstrated. His fundamental proposition is that as a general rule tuberculosis has its origin in early infancy and that, contrary to the view of Professor KOCH, the vehicle for the conveyance of this latent infection is milk. According to Professor BEHRING, therefore, the cause of active tuberculosis is not so much exposure to infection as the conditions of life which alter the soil of the individual who is already the bearer of the essential seed. Having regard to the divergency of views expressed by eminent observers the report of the Royal Commission on Tuberculosis, which is now pursuing its investigations, will be awaited with considerable interest.

The Harben lectures were made the occasion by Professor F. HUEPPE for the circumstantiation by means of concrete examples of the theoretical views which he propounded in 1893. The adaptation of cell activities to the changing conditions of environment and the variation of bacterial species in accordance with the circumstances of time and place were illustrated by examples of susceptibility to, and immunity from, tuberculosis and other diseases and by the morphological and metabolic variations of the tubercle bacillus itself in its varying conditions of parasitism in different hosts.

Some interesting observations on tuberculosis of the nervous system were made by Dr. E. F. TREVELYAN in delivering the Bradshaw lecture before the Royal College of Physicians of London. He drew attention to the forms which the tuberculous infection may assume in the nervous system, to the mode of infection of the brain and meninges, to the information which may be obtained by examination of the spinal fluid obtained by puncture, and to the prognosis of tuberculous affections of the nervous system.

Dr. A. MARMOREK, the late head of the staff of the Pasteur Institute at Paris, has announced that he considers that he has been able to isolate the true toxin from cultures of the tubercle bacillus. This toxin he injected into horses and finally obtained a serum containing either the attenuated toxin or an autotoxin secreted by the horse. He tried the toxins on patients suffering from tuberculosis but the cases were too few to allow any definite opinion to be formed as to the therapeutic value of this serum.

Small-pox.

In THE LANCET of August 8th (p. 377) we published a valuable paper by Dr. J E SANDILANDS on the vaccination statistics of the Metropolitan Asylums Board in connexion with the recent exceptional prevalence of small-pox in London. Having for a considerable time occupied the position of assistant medical officer in actual attendance on patients in the hospital ships at Dartford, Dr. SANDILANDS writes with authority concerning the behaviour of small-pox, both in vaccinated and in unvaccinated persons, and he has utilised his opportunities for observation in a way that should carry conviction to unprejudiced minds as to the paramount power of vaccination as a prophylactic. The figures in the Asylums Board reports emphasise the same lesson that has been taught by previous small pox epidemics, which is that the incidence of attack is overwhelmingly greater during childhood than in later years, the mortality at the earlier ages in the recent epidemic having averaged from 20 to 50 per cent. of the cases treated.

The difficulty which small-pox occasionally presents in the matter of diagnosis was well illustrated by an epidemic which occurred in Trinidad. So mild was the type that the disease was considered by the Trinidad Medical Board not to be small-pox but was regarded as "epidemic varioloid varicella." Subsequent investigation by Mr. J. F. E. BRIDGER, however, went far to prove that the malady was a mild form of small-pox.

Typhoid Fever.

The paper communicated to the Royal Society by Dr. ALLAN MACFADYEN marked a decided advance in our knowledge of the cell physiology of the bacillus typhi abdominalis, whilst the full confirmation of the preliminary results obtained by him promises a prophylactic and therapeutic agent in the treatment of typhoid fever which may replace the antityphoid "vaccines" and sera at present in use. Dr. MACFADYEN, writing in conjunction with Professor DEWAR, showed that many species of bacteria could be exposed to the temperature of liquid air for considerable periods of time without destruction or, indeed, loss of vitality. At this temperature, too, bacterial cells are frozen into hard fragile masses which can be successfully triturated *per se* at a temperature which precludes the possibility of autolytic changes and the cell plasma can be subsequently obtained from the disintegrated mass. Proceeding onwards in the investigation the typhoid cell juice was employed in the immunisation of animals, with the result that animals thus treated were found to yield an "anti" serum which was at once actively bactericidal and also antitoxic. Animals inoculated first with the antiserum and subsequently either with lethal doses of living typhoid bacilli or of toxic cell plasma were completely protected. Again, animals were inoculated with lethal doses of living bacilli or of toxin and some time later were injected with curative doses of the antiserum. These animals recovered whilst death resulted in the control animals which were similarly inoculated but were not treated with the serum.

Plague.

An important report was issued during the year by Dr. W. J. R. SIMPSON on the Causes and Continuance of Plague in Hong-Kong. After a consideration of the several factors upon which the spread of the disease depends Dr. SIMPSON recommended to the Government the following measures: (1) notification of plague from China by weekly bulletins from consuls; (2) the inclusion of a special plague organisation in the sanitary administration; (3) a reorganisation of the sanitary department to include medical inspection of shipping and junks and the appointment of a sanitary commissioner for the colony; and (4) the amendment and consideration of the public health ordinances.

We have during the year chronicled regularly in our columns, through the medium of our foreign correspondents, the prevalence and spread of plague in different parts of the world, and a fuller consideration of the subject will be found in this article under the heading Public Health.

Leprosy.

Mr. JONATHAN HUTCHINSON has for many years been the chief upholder of the theory that leprosy is associated with the ingestion of putrid fish. In order to obtain further evidence he made journeys to South Africa and to India and on his return from the latter country delivered an address at the Medical Graduates' College and Polyclinic in which he maintained the views which he has advocated so long. He considers that by his visit to India he has overcome many of the objections which had been raised against his theory. In one particular, however, he has modified it: he acknowledges that the disease may be transmitted by "commensalism"—that is to say, by food which has become infected by the leper's hand.

Sleeping Sickness.

Owing to the energetic steps adopted by the Royal Society in despatching commissioners to Uganda to investigate the causes and means of transmission of sleeping sickness much has been learned in reference to the etiology of this disease. Readers of THE LANCET have been kept fully informed of all the steps in the most interesting pathological story of the year. Dr. A. CASTELLANI was the first observer who described trypanosomes as occurring in the cerebro-spinal fluid of patients suffering from this disease. The commission sent out by the Royal Society consisted of Lieutenant-Colonel D. BRUCE, R.A.M.C., Dr. D. N. NABARRO, and Captain E. D. W. GREIG, I.M.S. The conclusions of their last report are as follow: 1. That sleeping sickness is caused by the entrance into the blood and cerebro-spinal fluid of a species of trypanosome. 2. That this species is probably that discovered by FORDE, and described by DUTTON from the West Coast of Africa, and called by him "trypanosoma Gambiense." 3 That the so-called cases of trypanosoma fever described from the West Coast of Africa may be, and probably are, cases of sleeping sickness in the earliest stages. 4. That monkeys are susceptible to sleeping sickness and show the same symptoms, the disease running the same course, whether the trypanosomes injected are derived from cases of so-called trypanosoma fever or from the cerebro-spinal fluid of cases of sleeping sickness. 5. That dogs and rats are partially susceptible but that guinea-pigs, donkeys, oxen, goats, and sheep up to the present have shown themselves absolutely refractory. 6 That the trypanosomes are transmitted from the sick to the healthy by a species of tsetse fly (glossina palpalis) and by it alone. 7. That the distribution of sleeping sickness and that of the glossina palpalis correspond. 8. That sleeping sickness is, in short, a *human* tsetse-fly disease.

Lead Poisoning.

During the year a report was issued by the medical department of the Local Government Board which gives details of a prolonged research undertaken by Dr. A. C. HOUSTON on the power which certain moorland waters possess of dissolving lead. The object of the research was to determine the causes of the acquisition by water of this "plumbo-solvent" ability and to ascertain the extent to which the large moorland gathering grounds of Lancashire and Yorkshire are liable to furnish water capable of exercising the objectionable property of acting upon domestic lead service pipes. The results obtained by the research are, briefly, that a water which is capable of dissolving lead is acid and its acidity is ultimately to be referred to drainage from peaty soil; that the formation of acid takes place within the peat itself and results from the action of specific bacteria which when isolated possess the power of rendering by their growth a sterile neutral decoction made solely from peat both acid and possessed of "plumbo-solvency." Fortunately there seems to be no difficulty in safeguarding a population supplied wholly or partly from moorland sources from risk of receiving water capable of dissolving lead.

Cancer.

Ever since the KING publicly expressed his desire that the deplorable increase of cancer prevailing throughout his dominions should receive the earnest attention of the medical profession with a view, if possible, to the discovery of means for its prevention, the subject has engaged a large share of public notice. During the past year a considerable amount of research work has been accomplished but the results are as yet too uncertain to bear the weight of authority.

In a paper published in the first volume of the *Archives of the Middlesex Hospital* by Mr. C. R. C. LYSTER, the medical officer in charge of the electrical department of that hospital, information is given which seems to promise hope for the future. In speaking of the effect which the x rays have upon cancerous growths he says that a very large number of cases have been relieved of pain and that in a certain number the growth has undergone a definite retrogression. Of all the new growths the rodent ulcers are by far the most satisfactory to treat. The cases that have been under treatment have varied from those exhibiting small recent spots to the most extensive and old standing lesions. They have all shown a great tendency to improve; the more recent ulcers have quickly healed, leaving a healthy scar and there had been no recurrence up to the time of publishing the report. In cases of rodent ulcers of long standing and with considerable loss of tissue the tendency to heal has been remarkable but after a time recurrence is not unusual and this seems to be more difficult to deal with than is the original ulcer. Of other growths experience so far seems to show that the best results are obtained in cases of mammary carcinoma, especially in the recurrent forms. In a favourable instance the main effects of treatment are relief of pain, healing of ulceration, and a shrinking or disappearance of the growth. Sarcomata are not so amenable to treatment as are carcinomata. The cases which are apparently the least benefited are the epitheliomata, or, as they are now called, the squamous carcinomata, and this is more especially the case after secondary infection of the lymphatic glands has occurred. Mr. LYSTER very wisely uses the word "retrogression" in preference to the word "cure," for, as he says, in the present state of knowledge the utmost that can be said is that the disease is "arrested." With regard to the use of high-frequency currents in malignant disease, it is believed that the good results claimed for this therapeutic measure are due more to the tonic action of the rays than to any direct action on the growth itself. Cases of rodent ulcer and epithelioma were submitted to the action of radium and also to pitch-blende, the application of the latter substance being of particular interest as it is far more easy to obtain than radium; the results of the treatment have not yet been published.

In THE LANCET of Nov. 14th, p. 1374, we published a full report of the address on Dr. OTTO SCHMIDT'S Specific Treatment of Cancer which was delivered by Dr. H. JOSSÉ JOHNSON before the Abernethian Society of St. Bartholomew's Hospital. Dr. SCHMIDT claims to have isolated the parasite of cancer in pure culture and also to have discovered a new serum for the treatment of the disease. As we stated at the time, until fuller information is afforded we are not able to express any definite opinion on the subject.

A very suggestive paper on the resemblances exhibited between the cells of malignant growths in man and those of normal reproductive tissue was read before the Royal Society on Dec. 10th by Professor J. B. FARMER, F.R.S., Mr. J. E. S. MOORE, F.L.S., and Mr. C. E. WALKER. The paper, an exhaustive abstract of which is published in this issue of THE LANCET, was the result of joint work, each observer approaching the problems from an independent standpoint. The possible bearings of this important piece of original research cannot yet be estimated, but the Cancer Research Committee has the matter under its notice.

The annual report of the Cancer Research Committee for the year shows good work to have been done. We published in our columns a very interesting paper on the quantitative and qualitative relations of toxin and antitoxin by Dr. E. F. BASHFORD, general superintendent of the Cancer Research Fund, which sufficiently showed that the committee has in its executive officer a sound and able pathologist.

The Influence of Brain Power on History.

Sir NORMAN LOCKYER, in delivering the Presidential Address before the British Association for the Advancement of Science at Southport, pointed out that the nation at present suffers from the absence of a powerful, continuous, reasoned expression of scientific opinion and urged that the English should be armed as other nations are with efficient universities and facilities for research to "uphold the flag of Britain in the domain of learning and discovery." He also urged that in addition to our many existing councils another is required to secure that the benefits which a proper coördination of scientific effort in the nation's interest can bring shall no longer be neglected.

Lectures of the Year.

We published in full in THE LANCET as usual the official lectures delivered before the Royal College of Physicians of London. The Lumleian lectures were delivered by Dr. T. R. GLYNN who chose as his subject, Infective Endocarditis mainly in its Clinical Aspects. He dealt with the matter in a very comprehensive manner, laying some stress on its etiology. He pointed out that the disease is commoner in males than in females; that it is prone to attack the debilitated, the intemperate, and the cachectic; that it follows anæmia, parturition, Bright's disease, pneumonia, and rheumatism; and that it is very frequently associated with antecedent sclerotic changes in the endocardium. In the great majority of his cases the mode of entrance of the pathogenic organisms could not be ascertained. Dr. A. S. F. GRUNBAUM delivered the Goulstonian lectures, selecting as his theme, Theories of Immunity and their Clinical Application. He gave an account of what is known concerning antitoxins, hæmolysins, and cytotoxins, and drew attention to actions, other than antitoxic and bactericidal, of curative sera. The Croonian lectures were in the hands of Dr. C. E. BEEVOR, the subject being Muscular Movements and their Representation in the Central Nervous System. This subject is naturally an involved one but the lecturer treated it in a most able and complete manner. As already stated, the Milroy lectures were given by Dr. BULSTRODE on the Causes, Prevalence, and Control of Pulmonary Tuberculosis and the Bradshaw lecture by Dr. TREVELYAN on Some Observations on Tuberculosis of the Nervous System.

SURGERY.

Aseptic Surgery.

The tendency to the replacement of antiseptic by aseptic surgery still continues but in many instances zeal has far outstripped knowledge and many without an adequate bacteriological training have adopted so called "aseptic" methods, with the result that primary union occurs more rarely than should be the case. A judicious blending of the two methods is the most useful, practically sterilisation by heat of the instruments and dressings replacing the former sterilisation by antiseptics and as far as possible the contact of antiseptics with the wound being avoided. As Mr. W. WATSON CHEYNE has pointed out, there appears to be at present a disposition to discard buried sutures as it seems to be thought that it is very difficult to guarantee the aseptic character of a silk suture, though this is rather an indictment of the mode in which the aseptic method is carried out. Mr. A WEBB JONES urged that it was perfectly possible to employ the aseptic method even in such a place as Wady Halfa, where he had been performing operations for 15 months, but he agreed that in circumstances such as are met with there dressings permeated with antiseptics would have an advantage over those merely sterilised.

Film Dressing for Wounds.

Mr. PEYTON T. B. BEALE has devised a new form of film dressing. It consists of thin films of a cellulose derivative, called velvril; these are transparent, tough, elastic, and impermeable. When the operation has been completed a piece of sterilised velvril is cut, large enough to cover the wound and one inch beyond; this is placed over the wound after the wound and the skin around it have been painted with a solution of velvril in acetone. A pad of wool and a bandage complete the dressing. The transparent film enables the wound to be examined from time to time and if left to itself it peels off in 10 or 12 days, though it can readily be removed earlier if necessary. This dressing promises to be useful.

Operation for Perforation in Enteric Fever.

As in other recent years, the surgery of the abdomen has received more attention than perhaps rightly belongs to it, but at present this branch of surgery is advancing rapidly and therefore attracts much notice. The number of instances in which the abdomen has been opened with success for perforation in enteric fever is steadily increasing and several other cases of this operation have been recorded during the year. Mr. A. A. Bowlby, who already had had a successful case of this nature, has recorded a second in which also the patient recovered. As Mr. Bowlby pointed out, in both of his cases the perforation occurred late in the disease when the fever was practically over and the general condition of the patient was fairly good, but in most cases perforation, should it take place, occurs earlier and the prognosis is therefore graver. Dr. H. W. G. Mackenzie has recorded two cases of recovery after operation for enteric perforation; they were under his care and that of Mr. W. H. Battle.

Intussusception.

It is becoming generally recognised that acute intussusception in nearly all cases requires immediate operation. Should it be limited to the large bowel it may be possible to remove the invagination by inflation or injection and this treatment certainly deserves a trial, but if the bowel be involved above the ileo-cæcal valve a laparotomy is imperatively necessary. Mr. Hugh M. Rigby has recorded the notes of seven cases of acute intussusception which were admitted within a period of nine days into the surgical wards of the London Hospital. The period of nine days started on Dec. 26th and it is not unlikely that the injudicious and excessive feeding associated with Christmas may be responsible in great part at least for the occurrence of the condition. One case was moribund when seen and was not submitted to surgical treatment, dying shortly after admission. Of the remaining six cases one required an enterectomy and died but the other five cases recovered after laparotomy.

Dr. Llewellyn A. Morgan has published the notes of a case of acute ileo-colic intussusception in a child one year and eight months old. Laparotomy was performed but death ensued within 40 hours of the onset. A point of interest was discovered post mortem, some tuberculous ulceration of the bowel being found in the intussuscepted portion. Dr. J. E. Webb has recorded an interesting case of intussusception on which he operated with success although the operation had to be done in a small cottage and with the light only of a lamp and a candle. The successful result in this case is to be attributed to the early correct diagnosis and to the energy and skill owing to which the operation was performed within six hours of the onset of the symptoms, although 15 miles had to be driven in the severest weather before the proceedings could be carried out.

Retroperitoneal Herniæ.

Herniæ into the peritoneal fossæ have been described from time to time, but the profuse nomenclature has done something to retard the general recognition of the chief varieties of these "retroperitoneal" herniæ. Dr. C. T. Andrew discovered in a subject in a dissecting room a hernia in the fossa duodeno-jejunalis, the contents comprising the whole of the small intestine with the exception of the lower six inches of the ileum. There was no evidence of any strangulation. Mr. B. G. A. Moynihan, from the description given, was inclined to think that the hernia was in the fossa of Landzest, forming what is called a "left duodenal hernia."

Dr. Priestley Leech has described a case of left duodenal hernia which had become strangulated. The patient was a man, 26 years of age, and on the night after a hearty supper he began to vomit and had complete obstipation. There was a history of two similar but milder attacks. Laparotomy was performed and the retroperitoneal hernia was discovered. About three feet of bowel were readily withdrawn from the pouch and the abdomen was closed. The patient recovered.

Volvulus of the Sigmoid Flexure.

Mr. H. W. Allingham and Dr. E. Chittenden Bridges have recorded a case of chronic volvulus of the sigmoid flexure in a man, 54 years of age. He had been subject for 30 years to attacks of constipation recurring at intervals of from four to six weeks, lasting five or six days, and accompanied by much pain in the lower half of the abdomen. The attack commenced with abdominal pain and marked constipation though flatus passed; vomiting had occurred. Castor oil produced several motions and much pain. The symptoms gradually grew worse and an operation was performed. When the abdomen was opened the sigmoid flexure was found much distended and attached by many adhesions to the mesocolon so that the sigmoid was twisted on itself. The adhesions were broken down, the volvulus was reduced, and the sigmoid flexure was attached by two sutures to the abdominal wall to prevent a recurrence of the volvulus. The patient recovered and no return of the symptoms occurred although when the account was written 12 months had elapsed since the operation.

Mr. G. J. Arnold has reported a case of some interest. A medical man, 63 years of age, had had two attacks of acute intestinal obstruction arising from volvulus of the sigmoid flexure and on each occasion a laparotomy had been performed and the volvulus had been reduced, and at the second operation some measures were said to have been taken to prevent a recurrence. A third attack of abdominal pain occurred with nausea but no vomiting. The patient himself wished for an immediate operation and Mr. Arnold opened the abdomen and found in addition to a few adhesions along the line of the former incision an enormously dilated descending colon. This distension was due to a constriction of the sigmoid flexure by a piece of small intestine adherent to the abdominal wall and it was found that several feet of small intestine had passed through the mesosigmoid. Recovery was rapid and complete.

Intestinal Obstruction.

Mr. T. Crisp English has recorded three cases of acute intestinal obstruction which were in St. George's Hospital under the care of Mr. Clinton T. Dent. In one case the cause was a thick band of peritoneal adhesion which produced a sharp kink of a piece of small intestine; recovery ensued. In the second case numerous adhesions in the left iliac fossa had bound down the bowel. The division of these relieved the obstruction but the patient did not rally from the operation. In the third case an omental band in the right iliac fossa constricted a coil of intestine. The chief point advanced by Mr. English is the value of irrigating the intestines during the operation with normal saline solution at a temperature of 108° F. This, he urges, diminishes the distension of the intestines, lessens shock, prevents subsequent adhesions, and, by increasing the secretion from the kidneys, assists in the elimination of toxic products. He also insists on the importance of systematically washing out the stomach in cases of intestinal obstruction both before and after the operation. Both these procedures are of great value and deserve more extended employment.

Surgery of the Gall-bladder.

The surgery of the gall-bladder has now reached a position of great importance, for it is recognised that cholelithiasis, apart from its own immediate evils, is frequently the precursor of malignant disease of the gall-bladder. Dr. C. A. S. Ridout records a case under the care of Dr. G. Stokes Hatton in which 449 gall-stones were removed from the gall-bladder. They averaged about the size of a large pea. The gall-bladder was drained and the patient's after-progress was satisfactory.

Dr. John H. Gibbon has published a case of gangrenous cholecystitis. The patient was a woman, aged 52 years, with a history of indigestion, nausea, and vomiting. Her attack began with pain in the left hypochondrium and vomiting; her temperature was 102°. When the abdomen was opened three days after the inception of the illness the gall-bladder was found to be distended and its fundus of a dark-purple colour. The gall-bladder was incised and the wall was found to be gangrenous in its whole thickness. Cholecystectomy was performed and an uneventful recovery followed.

Mr. FREDERIC S. EVE has published three cases of cholecystectomy. In the first case the gall-bladder contained purulent fluid and was at first drained. Later, to cure the biliary fistula which remained, the gall-bladder was excised. In the second case the gall-bladder was distended and contained many stones but the fluid was sterile; cholecystectomy was performed. In the third case there was a little pus in the gall-bladder and the mucous membrane was ulcerated. The gall-bladder was removed. In all three cases rapid recovery took place. Mr. EVE considers that the gall-bladder is a structure which can be dispensed with without inconvenience and therefore he thinks that in the future cholecystectomy will be more often performed instead of drainage in cases in which the gall-bladder is thickened and contracted.

Dr. H. A. LEDIARD has described a case of perforation of the gall-bladder occurring in a woman, aged 47 years. Many calculi were present and were removed and then the opening into the gall-bladder was closed by invaginating the edges and stitching with Lembert sutures, as was suggested by Mr. G. H. MAKINS. The operation was completely successful.

Mr. LEONARD A. BIDWELL has published notes of four cases of empyema of the gall-bladder, in all of which he employed drainage. Of the four cases three patients recovered and one died.

Hypertrophy of the Prostate.

The treatment of hypertrophy of the prostate when it leads to difficulty of micturition has excited much attention and given rise to no small amount of discussion. On the whole it may be said that most of those surgeons who have devoted special attention to this department prefer to enucleate the prostate and the results which have up to the present been obtained fully justify this opinion. Mr. P. J. FREYER'S statistics give a total mortality of less than 10 per cent., even when all deaths after the operation are included, though some of the fatal cases might not unreasonably be removed from the deaths. Dr. W. PRIOR PURVIS has reported a case in which he enucleated a mass from the prostate weighing six and a half ounces. The best treatment for this condition was discussed at the Swansea meeting of the British Medical Association and it was also a subject of discussion at a meeting of the Harveian Society where the debate was opened by a paper by Mr. C. W. MANSELL MOULLIN who entered somewhat fully into the whole question. There is no doubt that the more modern methods of treatment of hypertrophied prostate are superseding habitual catheterism which is full of septic dangers for the patient with enlarged prostate. The temporary favour which was accorded to vasectomy and castration for prostatic hypertrophy has been followed by almost complete neglect.

Aneurysm.

Traumatic aneurysms of large arteries are not common but two cases of this condition have been recorded in THE LANCET during the year. Dr. ALAN H. MUIR narrates a case under the care of Mr. W. F. BROOK of traumatic aneurysm of the gluteal artery resulting from a fall on the buttock. The internal iliac artery was compressed digitally through an opening made in the abdominal wall. Then the sac of the gluteal aneurysm was opened by an incision six inches long in the line of the gluteal artery, the blood clot was turned out, and the artery was tied. The fissured fracture of the hip-bone which had wounded the vessel was seen. Complete recovery followed. Dr. J. CROPPER has described a case of traumatic femoral aneurysm which was under his care. It arose from a punctured wound inflicted four months before. The vessel was tied above and below the sac which was excised. The vein was wounded during the operation and the hæmorrhage was controlled by firm packing. The patient soon recovered.

The introduction of wire into the interior of an aneurysm is now rarely employed. Mr. D'ARCY POWER and Mr. G. H. COLT have published a case in which this was done. The aneurysm was situated on the abdominal aorta and was exposed by an incision over it and 80 inches of silver wire were introduced into the aneurysm and the opening was closed by a few Lembert sutures. The patient died 50 hours after the operation. At the necropsy a loop of wire was found projecting into the aorta. The instrument devised for the introduction of the wire is ingenious and is likely to be used in future whenever this operation seems to be indicated.

OBSTETRICS AND GYNÆCOLOGY.

The Anatomy of the Pregnant Uterus

During the past year two valuable contributions have been made to our knowledge of the anatomy of the pregnant uterus. J. CLARENCE WEBSTER has published a paper on the cadaver of a woman who died in the sixth month of pregnancy which he studied by means of frozen sections. The specimen is principally of interest in showing the extent to which the uterus may be displaced upwards by the distended bladder. The highest point of the fundus uteri is opposite the first lumbar vertebra, while at full term the normal level of the fundus is the disc between the first and second lumbar vertebræ.

The second case, published jointly by PINARD, SEGOND, and COUVELAIRE, is that of a patient delivered by Cæsarean section at full term whose uterus was bound down by peritoneal adhesions on its posterior and left lateral surface to the posterior wall of the pelvis and of the abdomen and to the intestines. After the delivery of the child the uterus was removed by hysterectomy. This interesting specimen demonstrates the fact that the fixation by adhesions of practically the whole of the posterior surface of the uterus is not incompatible with the development of pregnancy to full term. As a result of the presence of the adhesions the anterior wall of the uterus had developed to a very marked extent while the posterior wall remained almost entirely undeveloped. At the same time the lower uterine segment had undergone marked over-distension over an area on the left side corresponding to the position of the fœtal head. The case affords an interesting anatomical proof of the manner in which the so called incomplete retroflexion described by ROBERT BARNES in cases of incarceration of the retroverted gravid uterus may occur.

The Nutrition of the Mother and its Relation to the Size of the Child.

The view of PROCHOWNICK that it is possible to influence the size of the child by modification of the mother's diet is confirmed to a considerable extent by the observations of NOEL PATON in the case of guinea-pigs. By regulating the food of the mothers he was able to show that the weight of young per gramme of mother could be definitely altered. The average weight per litter in the underfed animals was no less than 28 per cent. below the weight per litter in normal well-fed animals. Physiologically the point of interest in these experiments is the demonstration of the limitations in the extent to which the tissues of the mother can be utilised for the construction of the embryo.

Ectopic Gestation.

Extra-uterine gestation has been the subject of numerous publications during the past year. Our knowledge of the changes that occur in the wall of the pregnant tube and also of the manner in which rupture of the tube is produced is much more complete than it was. The anatomy of the pregnant tube was fully considered in a paper published by J. R. ANDREWS, and the whole question formed one of the subjects of discussion at the meeting of the German Gynæcological Society in June of this year.

It is becoming more and more evident that the ovum in cases of tubal pregnancy is imbedded beneath the mucous membrane of the tube and is not simply attached to its surface. The free pole of the ovum, that is to say, the part projecting towards the lumen of the tube, is covered by a true decidua reflexa, or by organised clot, or by some of the folds of the mucous membrane representing such a decidua. The development of the tubal decidua is a constant condition, although the amount of its development varies considerably in different cases. In cases of tubal rupture the wall of the tube gives way, while in cases of early tubal abortion the covering of the free pole of the ovum becomes torn through. The part played by the epithelium of the villi in causing the destruction of the muscular tissue of the wall of the tube is not yet completely determined but no doubt it plays an important part. The occurrence of a primary abdominal gestation cannot yet be said to have been demonstrated beyond doubt but the existence of ovarian gestation is now accepted by all observers. With regard to the question of treatment in accordance with the conservative tendency of recent gynæcological surgery, it is becoming more and more the custom with many obstetricians to adopt expectant treatment in the case of a limited peritubal hæmatocele due to tubal abortion and to operate in practically all other cases of this kind, while the abdominal route is more generally applicable and more often employed than the vaginal.

A work of much interest has been published by F. VON WINCKEL on the deformities of the fœtus in cases of ectopic gestation. He draws the conclusion that maldevelopments of the fœtus are much more common than is usually believed and occur in some 50 per cent. of the cases. He thinks that the contractions of the fœtal sac, which are often well marked, play an important part in producing these deformities and diseases of the ectopically developed fœtus. It is interesting to notice that such deformities often disappear spontaneously if the fœtus continues to live.

Deciduoma Malignum

Two of the meetings of the Obstetrical Society of London were devoted to a discussion upon this most important disease. The subject was introduced by TEACHER of Glasgow who in an exhaustive and interesting paper dealt very fully with the whole matter. In connexion with the paper a large number of pathological specimens and microscopical sections were shown. The most interesting problem yet unsolved in connexion with this disease is its relationship to the tumours of apparently the same nature met with in the male.

TEACHER came to the following conclusions:—1. That the so-called deciduoma malignum is a tumour arising in connexion with a pregnancy and originating from the epithelium of the chorionic villi (or its forerunner, the trophoblast) which is of fœtal ectoblastic origin. The malignant hydatidiform moles may be regarded as a variety of chorion epithelioma. 2. That the chorion epitheliomata and malignant hydatidiform moles form a quite characteristic group of tumours clinically and pathologically and that they should be classified neither as sarcomata nor as carcinomata but as a distinct class *sui generis*. The most appropriate name is chorion epithelioma malignum. 3. That, in addition to the common tumours developing from a pregnancy, there are tumours containing precisely similar structures which are not connected with a pregnancy and which may occur in other parts of the body than the uterus and in either sex. The most probable explanation of these is that they are teratomata originating from some structure which has the morphological value of an included matured and fertilised ovum, and the chorion epitheliomatous tissues represent the actual trophoblast (chorionic epithelium) of the included ovum.

Tuberculous Disease of the Genital Tract

The importance of tuberculosis in the etiology of diseases of the genital tract is becoming more and more evident. This subject was discussed at the International Congress of Obstetrics at Rome last year and was also considered at the meeting of the British Medical Association at Swansea this summer. Papers were read and specimens were demonstrated by TARGETT, KYNOCH and ARNOLD LEA.

In the diagnosis of the condition TARGETT laid stress upon the freedom from pain, the frequency of dysmenorrhœa, and the absence of repeated attacks of peritonitis such as patients with the more common forms of pyosalpinx usually suffer from. The old view that amenorrhœa is usually present can no longer be held, as further experience has shown that the menstrual function is often not at all disturbed. The microscopical examination of the scrapings from the uterus is of little value in making a diagnosis as tuberculous endometritis is of very rare occurrence. As TARGETT pointed out, the tuberculous pyosalpinx has characters which often enable it to be recognised—viz., the persistence of the fimbriated extremity, the absence of adhesions on the serous surface, and the comparative thinness of the sac wall. Its contents are usually sterile and the uterine end of the tube alone exhibits the characteristic structure of tuberculous salpingitis.

X Rays and Violet Light Rays in the Treatment of Cancer

Evidence is accumulating as to the value of these light rays in the treatment of rodent ulcers and of true carcinomata. A considerable number of cases have now been recorded by CLEAVES, GRUBBE and others in which very marked benefit apparently has followed the use of the violet and x rays in cases of inoperable cancer of the uterus. It is to be hoped that we may soon have before us the results of a sufficient number of cases to enable us to form a definite conclusion as to the value of this method of treatment. The possible effects of the emanations from radium upon similar cases is a problem for the future to decide.

Pregnancy complicated with Uterine Fibroids

A discussion was opened by AMAND ROUTH at the meeting of the British Medical Association on the Management of Pregnancy complicated with Uterine Fibroids. He thought that expectant treatment was indicated in all cases unless there were urgent symptoms. Owing to spontaneous elevation of pelvic fibroids during the last few weeks or days of pregnancy threatened obstruction to labour did not, as a rule, persist. Sepsis with secondary infection of the fibroid was a serious danger in the puerperium. Induction of abortion should be abandoned. If urgent pressure symptoms supervened myomectomy was the ideal operation for subserous growths, failing that hysterectomy. After the child was viable reposition might be tried, leaving radical measures for a later date. A cervical fibroid might be enucleated from the vagina as an alternative to panhysterectomy. In all other cases of fibroids obstructing labour as a first step the child must be delivered by Cæsarean section followed by myomectomy, supravaginal hysterectomy with retroperitoneal treatment of the stump, or panhysterectomy. If during childbed fibroids became infected a prompt extirpation of the uterus might save the patient's life.

The Treatment of Prolapse of the Uterus

An important discussion upon this very common condition was held at the Congress of the German Gynæcological Society in Würzburg in June. It cannot be said that our knowledge was much increased by the contributions read. The difference of opinion was most marked in regard to the etiology of prolapse of the uterus. Is it to be regarded as a purely local affection or is it merely the result of general debility of the patient, and can prophylactic measures directed towards the correction of such errors in the general health prevent its occurrence? MARTIN thought that they could and laid much stress upon the importance of the patient's general condition, of physiological involution in childbed and at the climacteric, and of the disturbed nutrition that occurred in severe diseases, conditions in all of which there was extensive wasting of connective tissues and in which prophylactic measures were likely to be of much assistance. With the improvement of the general condition the local affection would improve also and bad cases would become much less common. Some of the other speakers dissented from this view and held that prolapse of the uterus was entirely a local condition and had no relationship at all to the general health. The infrequency of this distressing complaint amongst better-class patients seems to show that the importance of prophylaxis can hardly be overestimated and that the condition can be, and is, preventable except in a small number of cases in which infantilism, congenital backward displacements of the uterus, and imperfect development of the perineum play an important part in the production of the displacement. There was a general consensus of opinion that one or other of the forms of fixation of the uterus was indicated when operative treatment was required but that supplementary vaginal operations were always necessary. The results as to cure from all the various operations were about the same, while total extirpation of the uterus gave no better results than any other operation.

Obituary.

The list of deaths amongst obstetric physicians has been exceptionally heavy this year and includes such well-known names as MAX SÄNGER, HENRI VARNIER, GAILLARD THOMAS, WILLIAM PLAYFAIR, and JOSEPH GRIFFITHS SWAYNE.

OPHTHALMOLOGY.

The numerous points of contact that ophthalmology has with all other departments of medicine insure a full attendance at the meetings of the various ophthalmological societies in this and other countries and occasion the exhibition of numerous cases and the reading of many papers that awake interest, give rise to discussion, and lead to fuller and more exact knowledge of the different forms of disease that they illustrate. But this wealth and diversity of material render it difficult in a brief record of progress to do more than to allude to the chief events of the year, to indicate the principal topics that have attracted attention, and to mention a few of the more striking cases that have been seen and described. The Ophthalmological Society of the United Kingdom has elected as its president Mr. JOHN TWEEDY who also occupies the high position of President of the Royal College of Surgeons of England, an unprecedented combination of honours.

Congresses.

The meeting of the Egyptian Medical Congress was held at the close of last year at Cairo and the vexed questions of the nature, origin, and treatment of trachoma, which is there an endemic disease, were dealt with. It is said that partly as a result of this congress Sir ERNEST CASSEL was induced to place the sum of $200,000 at the disposal of the Khedive to institute a peripatetic ophthalmic dispensary with the object of relieving the appalling amount of remediable disease in Egypt. It is to be hoped that some permanent good may result from this kind gift if only by showing the people how much benefit may be effected by cleanliness and the adoption of very simple antiseptic measures. The President of the Ophthalmological Section of the British Medical Association at Swansea was Mr. HENRY E. JULER. Interesting papers were read by Mr. E. NETTLESHIP on Ocular Changes in Renal Disease; by Mr. G. HARTRIDGE and by Mr. CLAUD A. WORTH on Squint; and one on the Mechanism of Accommodation in Man by Dr. K. A. GROSSMANN. A new department of ophthalmology has been founded in the University of Oxford and Mr. ROBERT W. DOYNE has been elected as first reader. The post, which Mr. DOYNE is thoroughly qualified to fill, will, in conjunction with the ophthalmic hospital, afford many practitioners in and around Oxford the opportunity of keeping up, and extending, their knowledge of ophthalmic disease.

Uniformity of Notation.

The multiplication of journals devoted to ophthalmology, in which isolated cases are often reported in great detail, has led several observers to urge the necessity for greater uniformity being practised in such reports. Thus Dr. KNAPP of New York accepts and recommends the notation of the meridians of the eye originally proposed by Dr. HARLAN, in which the numbering commences at the nasal end of the horizontal meridian, runs to 90°, which is the vertical meridian, and then outwards to the opposite or temporal end of the horizontal meridian which is 180°. The general adoption of this notation by refractionists would prevent much confusion. Mr. LUCIEN HOWE points out that more uniformity is required in the numbering and in the use of prisms and suggests not only that the prisms should be ground with greater accuracy than is practised at present, but that the application of prisms to test the power of adduction and abduction, or the dynamic conditions of the eyes, should be conducted in the same manner, and, lastly, that the terms "latent" convergence and divergence should be replaced by those of esophoria, exophoria, and the like now generally used in America. Dr. CHARLES H WILLIAMS insists on the great importance for the safety of the public of more uniformity in the examination of the vision, colour sense, and hearing of all those employed on railways. A very interesting series of recommendations of the Section on Ophthalmology of the American Medical Association has been published and it would be well if all railway officials in the United Kingdom were examined on the lines that are laid down in this report, a condensed account of which will be found in the recently published Transactions of the American Ophthalmological Society for 1902.

Roentgen Rays.

The use of the Roentgen or x rays has become common in the treatment of various diseases of the eyes and the adjoining region, but especially in cases of epithelioma. Some very striking instances of the improvement effected in this affection have been placed on record (with illustrations) by Dr. W. SWEET of Philadelphia. The loss of the cilia and of the hairs of the eyebrows that has been observed in more than one instance suggests the advisability of protecting all but the diseased part with sheets of lead when this method of treatment is practised. The tube employed by Dr. SWEET was of low vacuum and was placed from six to ten inches distant from the part; the exposures lasted from five to ten minutes and the number of sittings varied from ten to 30 or more.

Affections of the Cornea.

The treatment of conical cornea has been the subject of discussion. Mr. A. STANFORD MORTON adopts the method proposed originally by Mr. HIGGENS of excising an elliptical portion from the apex of the cone and has had many successful cases. Others, as Dr. J. TATHAM THOMPSON and Dr. KARL GROSSMANN, prefer the application of the actual cautery to the apex, a plan originally proposed by Dr. ANDREWS and subsequently recommended and adopted by Mr. CANT and Dr. WILLIAMS and brought prominently into notice by Sir ANDERSON CRITCHETT. This plan either with or better still without subsequent perforation of the cornea with a needle seems to be the least dangerous. Dr. A. DARIER has brought forward a case of interstitial keratitis in which subconjunctival injections of tuberculin produced dangerous reaction. Mr. SYDNEY STEPHENSON has adduced statistics to show that from about 2 to 10 per cent. of all cases of interstitial keratitis are due to acquired syphilis and that the corneal affection occurs on the average about 11 years after the primary infection.

Glaucoma.

The propriety of recommending the operation of iridectomy in cases of chronic glaucoma, where vision is continuously or intermittingly failing, is the cause of much heart-searching on the part of the expert, because in most cases, founded probably on general impressions, it is believed that improvement rarely follows. Dr. CHARLES BULL of New York has done good service in tracing the results of iridectomy in chronic glaucoma and draws the conclusion that the earlier the diagnosis is arrived at and the operation performed the greater the success, and that as a rule those cases do best in which both eyes have been operated on simultaneously. The effect of resection of the superior cervical ganglion of the sympathetic has been observed by Dr. JOHN WEEKS of New York. He considers that in all forms of glaucoma, except the hæmorrhagic, iridectomy should first be practised. This may be supplemented by anterior sclerotomy in eyes still retaining vision and by posterior sclerotomy in those in which vision is lost. If these proceedings fail sympathectomy may be resorted to. In *simple glaucoma* he finds that good results are obtained in about 60 per cent. of the cases. Section of the anterior ciliary arteries before they penetrate the sclerotic has been found serviceable in cases of glaucoma by Dr. H. B. CHANDLER, and still another method of treating the chronic forms of this serious disease has been proposed and practised by Major H. HERBERT, I.M.S., which consists in the formation of a subconjunctival fistula, either by producing a subconjunctival prolapse of the iris or by infolding the conjunctiva. This plan was carried out in 130 cases, in all to which, except 18, a small iridectomy was previously performed. The results appear to have been satisfactory.

Cataract.

Major HERBERT, I.M.S., has given in a small volume the details of cataract operations as practised with such astonishing success in India. He prefers the combined operation, that is, he performs iridectomy under as far as possible aseptic conditions, the cornea being rendered insensitive with cocaine, but he also operates without iridectomy. *Out of 1172 operations in 26 months he had* only 93 poor results or complete failures. Major F. SMITH has very recently advocated the plan of extraction without opening the capsule and gives favourable statistics of this mode of operating in his hands.

An interesting article by Major F. P. MAYNARD, I.M.S., of the Medical College Hospital, Calcutta, in the *Ophthalmic Review* contains an account of the after results of 63 operations for depression of the lens performed by Indian "cataract prickers." Such records are rare. These show that about 46 per cent. of the cases operated on retained good vision after an average interval of nearly five years. Considering the rough instruments at the disposal of the operators and the want of attention in the after-treatment the results are more favourable than might be expected.

A special form of posterior cortical cataract has been described by Dr. W. ROBINSON as of frequent occurrence in bottle finishers in which occupation the workman is much exposed to the heat and the glare of furnaces.

Therapeutic Measures

The marked influence that adrenalin exerts on the blood-vessels and upon the blood pressure, constricting the former and increasing the latter, has naturally suggested its employment in various conditions of the eye in which the effects might be expected to prove beneficial. Thus, Dr. A. YVERT, Dr. WESSELY, Dr. KONIGSTEIN, Dr. MARQUES, Dr. A. DARIER, whose death has so recently occurred, and many others speak in high terms of its value when applied to the congested conjunctiva in a perfectly sterilised solution of 1 part in solution in 1000 parts of water. The local anæmia it occasions can be augmented with cocaine and the combination of the two remedies appears to be of great service in acute catarrhal affections, in rheumatic conjunctivitis, and in gouty congestion of the conjunctiva. Adrenalin is also useful in iritis and by its depressor action on the blood pressure in cases of glaucoma whether subacute or intermittent, and in cases of embolism of the retinal artery. It appears to be contra-indicated in such operations as iridectomy and cataract where the globe is opened, both Dr. DARIER and Mr. STEPHENSON having noticed intra-ocular hæmorrhage of a serious character. It has been injected subconjunctivally but *it must not be forgotten that it is a very dangerous poison*, and it is right to add that Mr. A. F. MACCALLAN and others have reported several cases of glaucoma in which the use of adrenalin caused increase of tension.

Subconjunctival injections of solutions of corrosive sublimate have been warmly recommended by Dr. DARIER whose treatise on Ocular Therapeutics has been translated by Mr. SYDNEY STEPHENSON. Dr. DARIER claims for this method a superiority to every other in cases of corneal ulcer, hypopyon-iritis, and inflammatory troubles in the uveal region; in retrobulbar neuritis and in various choroidal and retinal affections. He also advocates massage of the globe which, though anciently practised, is now seldom adopted. *The use of the sublimate in subconjunctival injection* has also been found very serviceable by Dr. C. S. BULL in orbital cellulitis, whilst Dr. VALOIS of Moulins reports two cases of *sympathetic ophthalmitis in which repeated injections of a* 1 per cent. solution of mercury cyanide into the orbit of the enucleated eye were followed by marked improvement, the vision of the sympathising eye returning to normal. The injections are productive of much pain, but granting the infectious nature of sympathetic ophthalmitis the local use of mercury in this manner is rational.

Amongst the many new remedies that have been tried with variable success may be mentioned dionine which in 5 per cent. solution in water acts as a mydriatic, effecting great dilatation of the pupil; as an analgesic, without anæsthetic action, relieving the deep-seated pain of iritis and glaucoma; and as a lymphagogue, dilating the blood-vessels and causing an increased flow of lymph through all the deeper-seated tissues, thus improving the nutrition of the cells and removing pathological products. Other remedies are largin, acting similarly to dionine; asaprol, a preparation of naphthol, employed with success by M. GALEZOWSKI in arthritic and rheumatic affections; acoin, which is both an anæsthetic and an analgesic; ichtargan, a combination of ichthyol and silver, which in 3 per cent. solutions advantageously replaces silver nitrate; protargol, in conjunctival affections; and hetol, the cinnamate of sodium, which in 1 per cent. solutions provokes marked phagocytosis, a condition favourable to the absorption of exudations and toxins. Many advantages over nitrate of silver are claimed by various writers for protargol, a combination of protein and silver, but considerable differences of opinion have been expressed in regard to its properties. Lastly, yohimbin is stated by Dr. H. SALOMONSOHN to possess a powerful and persistent anæsthetic effect in 1 per cent. solution and to act rapidly.

The Eyesight of Board School Children.

The testing of the eyesight of the children of the poor has been on several occasions brought under the notice of the School Board for London. It is estimated that about 600,000 children are being taught in the schools and the eight specialists who were appointed last year to inquire into the condition of their vision reported that about 10 per cent. of the children suffered from bad vision throughout the whole of their school life, whilst from 1½ to 3 per cent. had very bad vision, increasing progressively as they passed on to the higher standards. The impairment is in many cases due to errors of refraction remediable by means of appropriate glasses. The mode of dealing with these cases has not been as yet satisfactorily determined. The School Board authorities entirely disclaim any attempt to treat such defective children by medical examination and the prescription of spectacles. The children or their parents are told that their vision is imperfect and they must seek medical advice if they are to make any progress in their work at school. Application to the nearest hospital is, of course, the next step, but it is found that in practice the parents are unable or unwilling to lose a day's work, and if they do attend a hospital they are too poor to obtain the glasses, or too ignorant to insist upon the child persistently wearing them. Moreover, the out-patient room of the nearest general hospital is not always adapted for the treatment of refraction cases. The alternative is for the child to be taken to one or other of the half-dozen hospitals which have ophthalmic surgeons attached to them or to one of the ophthalmic hospitals. Again the question of time comes in but here the objection is raised by the surgeons. When 50 or 60 School Board cases present themselves in one morning, each, for the credit of the hospital, requiring prolonged examination and careful adaptation of glasses, the staff finds itself unable to cope with the numbers applying for relief and refuses to see more than a limited number. The only way out of the difficulty seems to be that the School Board should appoint a salaried officer whose time and attention should be devoted entirely to refraction cases.

Literature.

A new monthly journal entitled the *Ophthalmoscope*, conducted by Mr. SYDNEY STEPHENSON, assisted by Mr. C. DEVEREUX MARSHALL, has appeared. Amongst the more important works that have been published may be mentioned a "Treatise on the Diseases of the Eye, Ear, Nose, and Throat," by Dr. W. C. POSEY and Dr. JONATHAN WRIGHT and various authors; "Physiological Optics," by Dr. W. T. PORTER; "Practical Handbook of the Diseases of the Eye," by Dr. CHALMERS WATSON; "Refraction of the Eye and the Anomalies of the Ocular Muscles," by Mr. E. KENNETH CAMPBELL; "On Squint," by Mr. CLAUD A. WORTH; "The Pathology of the Eye," by Professor R. GREEF; "Pathologische Histologie des Auges," by Dr. SIGISMUND GINSBERG. New editions have appeared of "Ophthalmic Practice," by Mr. C. HIGGENS; "Refraction of the Eye," by Mr. GUSTAVUS HARTRIDGE; "Refraction of the Eye," by Mr. ERNEST CLARKE; "Ophthalmological Prisms," by Dr. ERNEST E. MADDOX; and "Atlas der Ophthalmoscopie," by Professor Dr. O. HAAB.

FORENSIC MEDICINE.

Actions by, or Against, Medical Men.

Since our last annual *résumé* several cases of high importance in which medical men have figured in courts of justice, both civil and criminal, have been recorded in our columns. At the Margate January quarter sessions WILLIAM HERBERT RAY was convicted of unlawful assault upon a girl and sentenced to six months' hard labour. We felt it to be our duty to challenge the equity of the verdict on the grounds that there was practically no corroboration of the testimony of the chief witness and to point out how serious are the risks incidental to medical practice. ROBERT FAWCITT GRANGER, a medical man, and his wife were charged at the Plymouth police-court with having grossly neglected their three children. They were found guilty and sent to prison for two months in the second division. It was proved in evidence that drink had been the cause of the downfall of the prisoners. The General Medical Council took a lenient view of Mr. GRANGER'S offence and have allowed him an opportunity of retrieving his position, he, on his side, promising abstention from alcohol. Professor J. W. BYERS of Belfast had the misfortune to meet a claim for damages for breach of promise of marriage made against him by a nurse. He was subjected to the meanest forms of persecution at the hands of the plaintiff and as showing the baseless nature of the action she did not put in an appearance when the case came on for trial at the Belfast city assizes. In proof of the high esteem in which Professor BYERS was held both as regards his personal and professional character he received a testimonial from a wide circle of fellow practitioners and citizens upon his triumphant vindication of his innocence. In Scotland, before the Lord Justice Clerk, Dr. JOHN CUNNINGHAM was sued for damages, laid at £1000, by the widow of a man named GILLIES who had died whilst under the influence of chloroform administered for the performance of a minor operation. The grounds of claim were that the deceased had been given the anæsthetic against his will and whilst in an unprepared state to inhale it, having partaken of a hearty tea No other medical man was present. Many practitioners of the highest repute gave evidence in refutation of the allegations and the jury returned a verdict for the defendant.

Antivivisection Tactics.

In the case BAYLISS *v.* COLERIDGE, heard recently in the King's Bench Division of the High Court before the Lord Chief Justice, £2000 were awarded as damages for libel. At a public meeting held by the National Antivivisection Society the defendant accused Mr. BAYLISS, assistant professor of physiology at University College, of having performed an operation on a dog without the animal having been properly anæsthetised, which meant that Mr. BAYLISS had rendered himself liable to a charge of misdemeanour for having contravened the terms of his licence granted by the Home Office. The defendant for the purposes of his speech had adopted a statement communicated to him by two ladies, members of a foreign antivivisection society, who had attended the physiological demonstration in question. The usual defence was pleaded: that in so far as the libel consisted of facts it was true and that it was published without malice and in the public interest. The "facts" were not substantiated in court.

The General Practitioner and Post-mortem Examinations.

The London County Council, desirous for the public benefit of assisting coroners in the discharge of their official duties, passed a recommendation that in cases of special difficulty the services of a medical man specially versed in pathological knowledge should be available. One coroner in particular adopted the suggestion to a greater extent than was intended by the Council, in that he called to his aid a gentleman nominated by the Council in a large number of ordinary post-mortem examinations to the exclusion of other medical men having more intimate knowledge of the cases to be inquired into. This was felt to be a real grievance by the great bulk of general practitioners who naturally considered themselves slighted, besides being deprived of customary fees. We felt bound to espouse their cause, firstly, on account of the questionable legality of the procedure and, secondly, because in our opinion the vast majority of medical practitioners are fully qualified to conduct necropsies in cases where no particular difficulty is likely to arise. It is with pleasure that we record the fact that the cause of the friction has considerably abated. *Apropos* of the subject under consideration we published a very able paper by Dr. H. H. LITTLEJOHN, though we could not subscribe to his chief contention that post-mortem examinations made for the purpose of judicial inquiries should be intrusted solely or mainly to expert pathologists.

Legal Cases of Medical Interest.

An unusual number of appalling crimes inquiries into which were largely based upon medical evidence have been perpetrated during the year. That which aroused the greatest public interest was investigated at the Chelmsford assizes before Mr. Justice LAWRENCE. An ex soldier named DOUGAL was charged with having murdered a lady named HOLLAND by shooting her in the head with a revolver. After having ingratiated himself in her favour to the extent that he persuaded her to live with him as his wife he took her life, presumably for the purpose of possessing himself of her property. He buried her body in a ditch and for four years lived within sight of the place of sepulture, to all appearance unmoved by remorse. To obtain her money he resorted to the most barefaced forgery which for a long time was unsuspected. His career, one long history of cruelty, lust, and crime, terminated on the scaffold. The trial disclosed an admirable instance of constructive identification. At the first the difficulties appeared likely to be unsurmountable, but in the end conviction was secured by evidence that left no loophole for the prisoner's escape. In this case, as in that of the late Miss S. F. HICKMAN, it was shown that the kidney of the deceased woman had resisted the agents of disintegration to a greater extent than the uterus. To Miss HICKMAN's death we need make no further reference, the facts having been so recently chronicled in our columns.

The practice of baby farming received a remarkable illustration and a powerful check when two women named SACH and WALTERS respectively expiated their guilt by the death penalty. The former culprit kept a "bogus maternity home" into which she admitted single women for confinement. This so far might have been an innocent calling, but it was in reality only the means for obtaining large sums of money for the ostensible purpose of getting the newly born children adopted by people of wealth and position. WALTERS was employed by SACH to murder the children and to dispose of their bodies.

To the list of notorious poisoners must be added the name of KLOSOWSKI, alias GEORGE CHAPMAN. After a four days' trial at the Old Bailey this criminal was condemned to death on March 19th. The original charge related only to the murder of a young woman named MAUD MARSH, but during the investigations into this case it was shown that KLOSOWSKI had done to death two other women by the same means—viz., antimonial poisoning. One had been certified as having died from obstruction of the bowels and the other from tuberculosis. The medical man who attended MAUD MARSH had also ministered to one of the other women during her fatal illness. The symptoms were much the same in the two cases—gastro intestinal irritation and progressive asthenia. It is noteworthy that not only was the family medical attendant baffled in his attempt to establish the cause of MAUD MARSH's illness but that at Guy's Hospital, where she was an in-patient, she was thought to be suffering from peritonitis. KLOSOWSKI was proved to have purchased a large quantity of tartar emetic some years before. The simulation of natural disease by the effects of antimony poisoning has on many previous occasions led to mistaken diagnosis. The bodies of KLOSOWSKI'S first two victims were remarkably preserved from decomposition, although one had been buried for a period of years. The motive for the crime in each instance seems to have been, in the words of the Solicitor-General, "cruel, pitiless lust."

In an action brought by a married woman who had sustained a severe nervous shock by seeing a house collapse in which she believed her children to be Mr. Justice BIGHAM held that the plaintiff was entitled to damages, although there was no physical impact of anything that injured her; he further held that she was so entitled in respect of injury through fear for her own safety but not in respect of injury caused by her fear for the safety of her children. In cases of this kind the result must necessarily depend largely upon medical evidence.

Among convictions of persons using titles or descriptions implying registration under the Medical Acts was that of LOUIS LAMB BAILLES, formerly a registered medical practitioner but removed from the Register after a conviction for felony. The defendant was employed by a person or persons known as the Dr. McLaughlin Company in connexion with the sale of "electric belts," and was charged in two summonses with using the description "Dr." implying registration and also with using that of "M.B.," of which his university had deprived him.

Several instances occurred during the year of the neglect of parents to secure medical aid for their children when suffering from illness or injury, some of which were followed by prosecutions under the Cruelty to Children Act, 1894. The majority of these cases were due to the religious beliefs entertained by the parents At an inquest at Manchester, however, it was proved that a parent whose child ultimately died from broncho-pneumonia had failed to call in a medical man and had instead, on the recommendation of his neighbours, had recourse to a quack medicine sold under the name of JACKSON'S Febrifuge. This was described in advertisements as capable of curing about 30 specified diseases and evidence was given that thousands of gallons of it were sold in the year. The coroner described the traffic in it as a "common swindle" and a verdict of death from natural causes was returned. In two instances persons influenced by religious fanaticism allowed their children to suffer from broken bones which they professed to heal by prayer and faith; in one of these a fine of £20 was imposed and in the other the father was sent to prison for a month.

Les Morts Bizarres.

Fewer deaths than usual from chloroform narcosis have been recorded We trust that future years will see a further reduction of this class of fatality from misadventure.

Two deaths from electric shock occurred at a public bath. The victims succumbed owing to a leakage from a charged conductor passing through their bodies. We pointed out that 200 volts would probably produce little effect if contact was made when the hands were dry and the feet were shod, whereas even six or eight volts would start tetanus in muscle of an individual immersed in water. As a precaution against the repetition of the above-mentioned disaster we advised that no electric-light fittings should be placed so that they could be reached by a person in a bath.

Two instances of fatal poisoning by carbon monoxide have been published in our columns. The late Mr. QUINTIN HOGG fell a victim at the Polytechnic to the effects of the products of incomplete combustion from a gas heater. Two children lost their lives owing to an escape from a defective gas pendant. In the manufacture of coal gas the proportion of carbon monoxide seems to be on the increase, the deficiency of illuminating power being supplied by the addition of an "enricher." In consequence of this excess of carbon monoxide a leakage of coal gas, barely recognisable by the smell, is distinctly dangerous to health. LAMIE in 1891 showed that carbon monoxide could be obtained from the desanguinated brains of dogs killed by the gas. That carbon monoxide is readily taken up by nerve tissue has been further proved by Croizet of Paris who has shown that after the acute symptoms of poisoning by the gas have passed away secondary manifestations may appear in the form of peripheral neuritis and trophic lesions.

The fact that certain fungi—e.g., penicillium glaucum—are capable of assimilating arsenic and giving off arsenical fumes has directed attention to another means by which the poison may be distributed from wall paper and other fabrics and also that fungi may be utilised for toxicological purposes in the detection of arsenic. M. E. APERT has published in the Transactions of the Société Médicale des Hôpitaux cases of Plumbism in Pearl Setters. The metal gained access to the system through the workers licking their fingers carrying lead-laden paste.

Dr. F. J. WALDO held an inquest on the body of a man who had died from acute poisoning by tannin. The deceased had fallen into a pit of tanning liquor; death resulted three and a half hours later from violent diarrhœa and vomiting. A similar case was recorded in Germany 40 years ago. It would seem that tannin is an irritant poison when taken in large doses.

A somewhat singular death from colchicine occurred in France. A man, aged 43 years, the subject of nephritis and gout, was ordered a capsule containing a quarter of a milligramme of colchicine and 20 grammes of salicylate of methyl eight times a day. To cut short an attack he took 12 capsules within the space of an hour. He vomited mucus tinged with black blood, passed blood in the motions and urine, and had muscular tremors which were exaggerated by excitement. The muscles became tender. Ecchymotic spots appeared on the limbs. The urine at the time of death—ten days after the ingestion of the poison—contained colchicine. The usual symptoms of colchicine poisoning—headache, abdominal [illegible], abundant vomiting, and diarrhœa—were absent.

Farmer v. Glyn-Jones: Stamp Duty on Medicines.

In this case a retail druggist had purchased from a manufacturer ammoniated tincture of quinine and had sold it with the label "Ammoniated Tincture of Quinine B.P. A well-known and highly recommended remedy for Influenza and Colds. Dose—1 teaspoonful in water every four hours until relieved. GLYN & Co., chemists, 15A, East India-road, E." It was contended on behalf of the Board of Inland Revenue that the preparation thus offered for sale required a stamp under the Medicine Stamp Duty Acts. It was decided by the Divisional Court that no stamp was required, the court holding that "a retail druggist who purchases a preparation of medicinal drugs from the manufacturers or from other persons and himself attaches to the bottles in which he retails it a label recommending it as a remedy for specified human ailments is not the 'owner, proprietor, original or first vendor' thereof within the meaning of 52 Geo. III., c. 150, and that if the preparation at the time that he so purchased it was exempt from stamp duty the fact of the retailer attaching the said label will not deprive it of the exemption." In this case it was held that a stamp was not required. As a result, however, of the discussion of the law in this and in other recent cases the Board of Inland Revenue has expressed its intention to press for the use of stamps in many instances where the duty has hitherto not been levied. According to one of the intimations thus given stamps will be required not only where admitted nostrums or secret remedies are sold and where the medicine is recommended in plain terms for the cure of a disease but also where any compounded medicine is labeled with the name of an ailment or of an organ of the body so as to suggest its use, as, for example, "cough mixture," "liver pill," except in the case of such compounded medicines being sold by qualified druggists either with a statement of the formula of the prescription naming the quantity of each ingredient or where the medicine has been compounded in accordance with a formula in the British Pharmacopœia or other well-known book of reference with a statement to that effect upon the label. The effect of any step such as that indicated on the part of the Board of Inland Revenue would be felt principally by those traders who deal in medicinal compounds without qualification to do so and by such druggists as carry on a somewhat similar trade. It may be anticipated that future prosecutions will render the law still clearer.

Death Certification without Inspection of the Body.

In more than one instance attention was called to the danger of fraud being promoted and assisted by medical men giving death certificates without actual knowledge of the fact of death. It is not necessary that a medical man should see the dead body of his patient before certifying, but he is empowered by the form of certificate issued to him to qualify his statement that death has taken place by the words, "as I am informed." Where by a mistake or by an intentional mis-statement a medical practitioner is induced to believe that a patient likely to die is dead a death certificate given by him may be used for the purpose of defrauding a life assurance office.

Cremation and the Detection of Crime.

The practice of cremation in relation to a possible impunity that might be enjoyed by murderers has loomed large on the medical horizon. The growing practice of destruction of bodies by heat had intensified the public misgivings. Although much could be said in its favour it was feared that the evidence of crime might be abolished and the interests of justice defeated. A further objection was that an innocent person suspected or accused of criminal poisoning would be unable to establish his innocence. In discussing the regulations to govern cremation framed by the special committee appointed to report on the question, we felt justified in supporting the procedure recommended. It has been demonstrated that arsenic can be detected in the ashes and bones of cremated bodies. During the process of combustion alkaline salts are formed which combine with the arsenic and fix it as arsenite or arseniate.

Lunacy and the Law.

As the result of a paper read by Sir WILLIAM GOWERS at the general meeting of the Medico-Psychological Association held at the County Asylum, Mickleover, Derby, on Feb. 12th, a discussion took place in the medical press and also in lay newspapers as to the provisions of the existing law with regard to the certification and detention of persons of unsound mind. It was suggested that such change was desirable as would enable patients who are on the verge of mental derangement, or who need temporary care only, to be detained and treated in institutions suited to their requirements without their being submitted to the same forms of certification as more seriously and more permanently deranged persons.

The Fees of Medical Witnesses.

A departmental committee, appointed to consider the question of allowances from public funds to prosecutors in criminal cases, made its report. It had heard evidence from persons representing various classes interested, and had considered among other matters the fees allowed to medical witnesses. The suggestions with regard to these contained in the report did not go quite so far as those made by the medical witnesses before the committee. They tend, however, to increase the fees payable to witnesses at assizes and at quarter sessions, as well as to introduce uniformity into the practice in respect of payment for medical evidence before magistrates at petty sessions.

The Medical Officer of the Ballachulish Slate Quarries.

A medical man, by a contract under which he was to attend the workmen at a slate quarry, bound himself to accept a month's notice from his employers (the directors of a joint-stock company) and to give up any other appointments which he might then hold in the neighbourhood and any private practice there. Having received notice to terminate his employment from the directors of the company he had an action brought against him by them to prevent his continuance in his private practice in the district and in the appointments which he had obtained in the neighbourhood. This he resisted, maintaining that his dismissal was so given that the other conditions he had entered into were not binding upon him. It was held in a court of law that he was bound by them and he subsequently failed upon appeal. The attitude of the men employed in the quarry, who warmly espoused the side of the medical man, no less than the inherent fairness of the medical man's claims, seemed likely from the first to bring about his re-instatement and we were glad to record in a recent number this happy issue. The case is of importance to medical practitioners who on undertaking appointments should closely study the conditions imposed and the contingencies which may arise under them.

Burroughs, Wellcome, and Co. v. Thompson and Capper.

Messrs. BURROUGHS, WELLCOME, and Co., the well-known firm of wholesale druggists, obtained in this action, which was heard in the Chancery Divison before Mr. Justice BYRNE, an injunction against the defendants to restrain them from passing off goods not of the manufacture of Messrs. BURROUGHS, WELLCOME, and Co as the goods of those manufacturers under the name of "tabloid" or "tabloids." These two words had been registered as trade marks by the plaintiff firm under the Patents, Designs, and Trade-marks Act of 1883 as "fancy words not in common use" and the defendants, by way of counter-attack, applied to have them removed from the Register of Trade-marks as not answering this description. The judge held that "tabloid" and "tabloids" were at the date of registration fancy words not in common use within the meaning of the Act and refused to grant the order asked for with regard to them. A large amount of evidence was given by medical witnesses and others showing that the words in question were regarded as the trade-marks of the plaintiffs and that their use was known to refer to the goods of the plaintiffs to the exclusion of those of other manufacturers.

DENTAL SURGERY.

Papers and other Communications.

During the present year Dr. W. MILLER of Berlin has published in the *Dental Cosmos* an interesting and valuable series of papers on Immunity in the Human Mouth. The results obtained justify him in concluding that the protective powers present in the human mouth are not to be accounted for by any antiseptic action on the part of the saliva but rather by the phenomenon of phagocytosis, by the struggle for existence, and probably by certain forces residing in the soft tissues which have not yet been investigated. In some researches on the comparative susceptibility of different teeth to caries Dr. MILLER has established the fact that there is a great difference in the rapidity with which different dentines are softened by acids and that this difference bears a certain relation to the density of the dentine and to the percentage of the calcium salts which it contains. Mr. W. ARBUTHNOT LANE, in a communication to the Odontological Society of Great Britain, drew attention to some of the mechanical factors which determine the development of the bones of the face. Many of his views are open to criticism by the dental surgeon but his paper has done good service by directing the attention of the latter to the constant association of various deformations of the teeth and jaws with imperfect performance of the functions of the naso-pharynx. In a paper on Electrotherapy Mr. C. A. CLARKE has described a tube for the x rays which can be used in the mouth. Attention has been drawn to the importance of asepsis in dental practice by Mr. W. GUY who pleads that more attention should be given to this essential of surgical practice at the dental hospitals. In connexion with chronic periodontitis Mr. J. G. TURNER has drawn attention to the occasional presence of thickening of the alveolar process over the region of the roots of the affected teeth, the appearance simulating exostosis. A case in which the mandible was fractured during the attempted removal of a third molar was recorded by Mr. J. H. BADCOCK. Several papers have been read before the various dental societies on somnoform and ethyl chloride and the general consensus of opinion of dental practitioners is that both agents under certain conditions possess distinct advantages over nitrous oxide or nitrous oxide and oxygen combined, the length and character of the anæsthesia and the ease of administration rendering these anæsthetics especially useful with children.

Operative Dentistry.

There have been numerous contributions dealing with the technique of the treatment of teeth by fillings and crowns; indeed, this aspect of dentistry seems to attract far more attention from the dental practitioner than do such important problems as the nature and cause of dental diseases. The use of gold as a filling is rapidly being displaced by amalgam. Since the publication of Dr. W. BLACK'S papers on Amalgams a great improvement has taken place in the preparation of the filings used to make such fillings and it is now possible to make amalgam fillings which will retain their shape. An advance, too, which is deserving of praise has been made by certain manufacturers who publish with the various fillings supplied the exact composition. In order that the best results may be obtained with amalgam it is necessary that the amount of mercury should bear some definite ratio to the amount of filings. Some difficulty has so far been experienced in carrying this out owing to the lack of simple and correct apparatus. This difficulty seems to have been overcome by Mr. W. J. MAY and in a paper read before the Odontological Society of Great Britain he has described and figured an ingenious apparatus for measuring mercury and a somewhat similar one for weighing the filings. Advance has been made in the methods of preparing porcelain inlays and crowns.

New Books.

Of new books Mr. A. HOPEWELL-SMITH'S on "The Histology and Patho-Histology of the Teeth" is perhaps the most important and is a valuable contribution to the subjects with which it deals. A useful little work entitled "Studies in Comparative Odontology" has been written by Mr. A. S. UNDERWOOD. Two books published in America are also worthy of notice, one by Mr. I. BROOMELL on the "Anatomy and Histology of the Mouth and Teeth" and the other by Mr. J. S. MARSHALL on "Injuries and Diseases of the Face, Mouth, and Jaws."

Obituary.

The obituary of the year includes Mr. J. C. WOODBURN of Glasgow who was for some time examiner in dental surgery at the Faculty of Physicians and Surgeons, Glasgow; Mr. HERBERT CANTON, R.N., who was for three years instructor in dental surgery at Haslar Hospital; Mr. PETER CROMBIE, one of the first to practise dentistry in Aberdeen; Mr. DANIEL CORBETT, jun., of Dublin, one of the promoters of the Dental Hospital of Ireland; and Mr. R. H. WOODHOUSE, for many years a member of the staff of the Royal Dental

Hospital, Leicester-square, and a man who was held in high esteem by his fellow practitioners.

ANATOMY AND PHYSIOLOGY.

The star of physiology is at the present moment undoubtedly in the ascendant. The violent diatribes of the antivivisectionists have defeated their own object by leading many unbiased and intelligent persons to inquire into the aims and uses of physiological research, with the result that they have satisfied themselves that the experimental physiologist is not necessarily cruel and hard of heart as his maligners have represented him to be and that although pain may be, and doubtless is, on rare occasions inflicted upon animals, it is no more than the surgeon is often called upon to give to his patients in the practice of his profession, whilst its object is in all instances, either directly or indirectly, to alleviate the suffering of man and with him of the animal kingdom in general. With the wider and more discriminative recognition of the objects of physiology by the public we find that laboratories intended for the prosecution of this as well as other departments of biology have been formed, or are in course of erection, in all the great cities of the empire, often fully equipped and at great expense. In those which are already established a large body of trained observers, employing very different methods of research, are unremittingly engaged in the endeavour to penetrate and to comprehend those secrets of nature appertaining to life which have so long resisted interpretation. The seed is germinating. The fair flower is still to come.

Digestion.

Amongst the most practical and interesting investigations that have been made during the past year are those upon digestion by Professor J. P. PAWLOW, the director of the physiological department of the Institute for Experimental Medicine in St. Petersburg. He, with his assistants, has been occupied with this subject for several years, but the general conclusions at which he has arrived have only lately been published in a small volume, well translated into English by Dr. W. H. THOMPSON, with the title of "The Work of the Digestive Glands." Professor PAWLOW'S experiments were chiefly made upon dogs, in some of which œsophagotomy was practised, so that the food given and swallowed could be removed before its entry into the stomach. In others by an ingenious operation a diverticulum or pouch of the stomach was formed which being shut off from the main cavity permitted examination of the pure secretion without any contamination of it with the products of digestion. In others, again, a pancreatic fistula was made, not by inserting a cannula into the duct, but by attaching to the skin of the abdomen the portion of mucous membrane on which the duct opens. The results obtained show that the gastric, pancreatic, and other secretions poured into the alimentary canal are by no means of uniform composition but that they vary both as to quantity and quality with the nature of the food, that they are adapted to the separately and successively occurring phases of the elaboration of the substances ingested, and that they are affected to a remarkable and unsuspected extent by psychic influences, so that he feels justified in saying that the appetite, excited by the senses of sight and smell, is the first and mightiest stimulus of the secretory nerves of the stomach, inducing it to secrete large quantities of the strongest fluid, as may be well seen in the make-believe or sham feeding experiments. In the case of the pancreas it appears that the gland responds, as it were, to the different kinds of food by variations in the proportions of the several enzymes that are ordinarily present, the largest proportion of proteid ferment being present in the juice secreted on a meat diet, of the amylolytic ferment on a bread diet, and of the fat-splitting enzyme or ferment on a milk diet. Professor PAWLOW has hence been led to attribute to the terminal fibres of the vagus a specific sensitiveness to the stimulus of each kind of food. Lastly, he considers that the intestinal juice, or succus entericus, contains a ferment to which he has given the name of "enterokinase" and which possesses the remarkable property of augmenting the activity of the pancreatic ferments and especially of the proteolytic ferment. It acts, therefore, as a ferment of ferments. Researches of a somewhat similar character have been undertaken by Mr. W. M. BAYLISS and Dr. E. H. STARLING who state as the result of their experiments that the secretion of pancreatic juice when acid is introduced into the duodenum is not due to reflex action but is consequent on the formation of a substance which they have named "secretin" by the cells of the intestinal mucous membrane. This substance is immediately absorbed into the blood-vessels and is carried by the blood to the pancreas where it acts as a specific stimulus to the gland cells. The presence of secretin in the venous blood returning from a loop of intestine into which acid had been introduced has been demonstrated by Professor WERTHEIMER.

Digestion in Plants.

But even Professor PAWLOW'S researches do not exceed in interest the results of the researches of Professor SYDNEY VINES, the President of the Linnean Society, upon the enzymes produced by plants. That certain plants are capable of capturing small insects has long been known, but it was reserved for DARWIN to demonstrate how this is accomplished by means of a secretion; how this secretion, in the case of the sundew, possesses a digestive power for albumin; and how, further, the ferment or enzyme of the sundew family is closely analogous to, or identical with, the pepsin of animals. Subsequent observers showed that the secretion of the pitcher plant and the juices of other plants like those of the papaw and pineapple had digestive powers, but some doubts having been cast on these statements Professor VINES was led to reinvestigate the subject and has arrived at the remarkable conclusion that proteases or proteid-digesting enzymes or ferments are to be found not only in a few insectivorous plants but in many plants and in many parts of plants, as in fruits, seeds, stems, leaves, tubers, and roots. The function of these proteases is to break up and to render soluble and diffusible the organic nitrogenous substances which the nutritive processes have built up and which are stored in their tissues. If plants thus commonly produce a protease in their interior it is not surprising that it should be exuded or secreted and discharged from the surface of the leaves in some particular instances, as for example, in the insectivorous plants. In passing, Professor VINES notices the great importance of such enzymes in promoting the digestion of the large quantities of vegetable substances consumed by ruminants and other herbivorous animals which thus ingest with the nutriment the means of digesting it. Professor VINES points out that the several proteases of the gastric juice, pancreatic fluid, and of the juices of plants differ not in kind but only in degree. They form, as he has expressed it, a series in which trypsin, active alike in peptonisation and in proteolysis, occupies a central position, having, on the one hand, pepsin with its active peptonisation and slight proteolysis and, on the other, erepsin or enterokinase with its active proteolysis and slight peptonisation.

Dietetics.

Some very interesting dietetic studies have been published by the United States Board of Agriculture, having special reference to the Chinese in New York. The Chinese are here shown to have a more varied and more liberal diet than the Europeans, and equally nutritive, fully supplying the wants of the economy during hard work and being at the same time very cheap. In the United States, as well as in this country, the extravagance of the poor arising from ignorance is accountable for much of the distress which they experience. Mr. ATWATER and Mr. WOODS, who studied the dietaries of many families living in the worst slums of New York, instance the case of the family of a mechanic who had received much help from the Association for the Improvement of the Poor and yet it was found that in his case the expenditure upon food was nearly twice that per head in the *family* of a well to do professional man, hardly anything being left over from the wages earned for fuel, lights clothing and the many other requirements of a family In fact all evidence goes to show that the poor should be educated in the principles of economy, and particularly in one department of it—cookery

The Action of Muscle

The Croonian lectures of the Royal College of Physicians of London were intrusted to Dr O E BELVOR who described the various methods of determining the action of muscles as the anatomical electrical, and physiological, and pointed out the fallacies and difficulties of each and discussed at considerable length and with much ability the particular muscles effecting the different movements of the several joints, together with the interesting subject of the action of antagonistic muscles Finally he gave the results of his own experiments made in conjunction with Sir VICTOR HORSLEY, in which every two square millimetres of the excitable portion of the cortex of the brain in the monkey were examined to determine the cortical representation of the several groups of muscles

K MUNCH has set forth an old view of the structure of muscle that the appearance of transverse striation is due to the closely compressed spiral arrangement of the anisotropous substance which *is best seen in the muscles of the* Myniops variolosus In accordance with this he maintains that the fibre does not contract but that the current of force circulating *in the disc spiral shortens the fibre*

The Minute Anatomy of the Spinal Cord

Professor C S SHERRINGTON, F R S, and Dr E E LASLETT have endeavoured to trace the origin and the course of the fibres composing the dorsal spino cerebellar tract They have shown that one of the laws of reflex action formulated by PFLUGER which is to the effect that reflex irradiation in the spinal cord spreads anteriorly or upwards does not hold good at least in the cat and the dog as well as probably in other mammals *and they supply evidence* that each spinal segment possesses many neurons with backward running axons which connect it with all the segments behind it

S VON SCHUMACHER finds that the nervus depressor is present in all mammals In man it is represented by the cardiac branch of the superior laryngeal nerve and the superior cardiac branches of the vagus The depressor terminates in all mammals in the wall of the aorta The nervi accelerantes terminate in the ventricles and auricles the left heart always having the larger supply The branches to the ventricles arise from the middle cervical ganglion and from the succeeding ganglia as far as to the sixth dorsal ganglion

Dr W E DIXON and Dr T G BRODIE have demonstrated that the vagi contain both broncho constrictor and broncho dilator fibres, each vagus supplying the lung of its own side only The sympathetic does not contain either dilator or constrictor fibres

Histology

The application of special methods of preparation of nerve cells and of blood corpuscles and of high powers of the microscope has revealed new features in these objects Thus Dr VLADISLAV RUZICKA of Prague describes a delicate network traversing the interior of the red blood corpuscles of the frog and Dr FRED MEVES of Kiel depicts annular markings in the red corpuscles of the embryo chick. A Russian microscopist Madame RACHEL PEWSNER NEUFELD has described in considerable detail and has *illustrated by* careful drawings a system of intracellular lymphatic canals in the ganglion cells of the spinal cord in mammals and Dr EMIL HOLMGREN of Stockholm describes intracellular branching cords in the spinal nerve cells of lophius piscatorius which stain intensely black with iron hæmatoxylin

Researches on Development

One of the most interesting results of recent researches by many observers whose statements have been collected by Mr THOMAS BRUCE and recorded in the *Quarterly Journal of Microscopical Science* is that the nucleus of the ovum in animals of different classes may be excited to activity by various physical agents and that the mitotic division of the nucleus which ordinarily results from fertilisation by the spermatic fluid can be effected by increase of osmotic pressure, by agitation, by elevation or by depression of temperature by exposure to hydrochloric acid in sea water and subsequent restoration to pure sea water and lastly by continuous exposure to a solution of certain specific chemical substances such as chloride of potassium and chloride of calcium In some instances development has proceeded to completion *so that true artificial parthenogenesis occurs*

Dr W H GASKELL has continued his researches into the origin of vertebrates which have led him to conclude that *this division of the animal kingdom arose from the group of* protostraca in common with the crustacea and arachnida and in particular from members of the protostraca in which *the arthropod characters had already become well developed* and were in fact nearer the trilobites than the polychæte worms The nearest living representative of the most *primitive* arthropod type is the remarkable animal named Peripatus

Sir MICHAEL FOSTER, finding probably that it was impossible to discharge efficiently the duties of professor in the School of Physiology at Cambridge, which he created and has developed with such remarkable success, and those which devolve upon him as the representative in Parliament of the University of London has resigned the professorship and also the secretaryship of the Royal Society His successor in the chair of physiology is Professor JOHN N LANGLEY who has long acted as a most capable assistant to Sir MICHAEL FOSTER in the maintenance of the high repute of the School of Physiology and is well known as an original worker and an admirable instructor Sir ARCHIBALD GEIKIE has been appointed in Sir MICHAEL FOSTER'S place as secretary of the Royal Society

Obituary

Several distinguished physiologists have passed away, amongst whom may be mentioned Professor IMMANUEL MUNK of Berlin who died at the early age of 51 years and whose researches on the absorption of fat in the intestines the general metabolism of the body and on physiological chemistry are well known He was a distinguished teacher Professor SIGMUND FUCHS professor in the Hochschule fur Boden Cultur or Agricultural College in Vienna, has died at the still earlier age of 44 years By the deaths of these two professors the *Centralblatt fur Physiologie* has the misfortune to lose both its editors in the course of a few weeks Professor LANDOIS whose work on physiology ran through so many editions in Germany and was translated into English by Professor W STIRLING, died at the close of 1902

Morphologists have to mourn the loss of two distinguished members of their body CARL GEGENBAUR of Heidelberg, who died at the age of 77 years, was a most energetic worker and original thinker as well as a voluminous writer and will long be remembered by his researches on the development and homologies of the vertebrata and upon histogenesis. JULIUS VICTOR CARUS who lived to the age of 80 years, was for a time the conservator of the University of Oxford Museum and took part in the *Challenger* expedition

Bibliography.

Numerous works of interest have been published, amongst which may be mentioned the following: Sir MICHAEL FOSTER, "Lectures on the History of Physiology during the Sixteenth, Seventeenth, and Eighteenth Centuries"; Dr. NOEL PATON, "Essentials of Human Physiology"; Mr. J. BLAND-SUTTON, "Ligaments, their Nature and Morphology"; Professor GOETTE, "Lehrbuch der Zoologie"; Dr. OTTO VON FÜRTH, "Vergleichende Chemische Physiologie der Niederen Thiere"; Dr. KARL SCHNEIDER, "Lehrbuch der Vergleichenden Histologie der Thiere"; Professor MAX VERWORN, "Die Biogenhypothese"; and Dr. JOHANNES SOBATTA, "Atlas and Epitome of Human Histology and Microscopic Anatomy."

ANÆSTHETICS.

The general features of the year's work may be summarised as the introduction of methods of greater precision for the administration of chloroform, some not unimportant advances in our knowledge of the action of that anæsthetic upon the organism, a widespread adoption of ethyl chloride and mixtures containing that body, and, finally, further contributions to our knowledge of local analgesia and the subarachnoid injection methods.

Medico-Legal and General.

More than one paper has appeared during the year as well as many scattered references, especially in the medical press of the United States of America, dealing with the status of the anæsthetist. England for many years has been exceptional in training medical men especially for the work of anæsthetists and now compels students to obtain special training in that branch of practice. Scotland also possesses specialists and the want expressed in the American medical press has, we gather, been met by the appointment of anæsthetists to the leading hospitals. In the columns of THE LANCET extended notice was taken of some disagreement between the controlling authorities and the staff of anæsthetists at a London hospital and the result certainly strengthened the position of the staff, while we believe it was beneficial to the best interests of the hospital in question.

The question of the status of the anæsthetist was introduced by a letter in our correspondence columns and in commenting upon it we pointed out that the trend of professional feeling, as well as that of the public, was towards a more adequate appreciation of the services rendered by the anæsthetist. On the other hand, such appreciation carried, we thought, an increased obligation that the anæsthetist should recognise his own limitations and the heavier responsibilities of the surgeon. A discussion upon this question has recently appeared in our columns.

A case of much interest was reported in THE LANCET of April 25th, p. 1183, in which the wife of a man who died under chloroform sued the medical man for damages. The verdict was for the defendant. Much expert evidence was adduced and much discussion followed. That the profession must be prepared for more frequent charges in connexion with anæsthetisation seems probable and the anæsthetist must in such an event be able to show that he possessed reasonable skill and took all proper precautions to achieve a successful issue. In another case[1] no verdict was given as the jury disagreed and a new trial was obtained upon a technical point.

Chloroform.

Almost from the first introduction of this anæsthetic the doctrine of its safety being dependent upon its dilution began to be appreciated. The methods, and their name is legion, which promised a dosimetric system of giving chloroform have all lacked some essential. In the most recent attempt Mr. A. VERNON HARCOURT[2] provides an apparatus which not only regulates the dilution of chloroform in percentages but gives a maximum of about 2·5 per cent. and supplies an index by which the anæsthetist can at once see the *strength* of the vapour inhaled but can at will increase or decrease it. As the inhaler depends upon the aspiration of the patient during inspiration the actual quantity of anæsthetic taken is decided by the depth and rapidity of the respiration. The amount, however, is quite subsidiary to the dilution, so that we are in harmony with those observers who, having tested this inhaler, speak well of it.[3] Dr. A. D. WALLER[4] describes and claims as a valuable means of giving exact percentages the mechanical chloroform inhaler suggested by Dr. DUBOIS of Lyons. With this instrument the objection, if objection it be, to which we refer above is removed, but in its place is the more elaborate complication of the mechanism of Dr. DUBOIS'S instrument. This is a drawback even in hospital work and still greater in private practice. It is a matter for congratulation that the rational view of the action of chloroform—that it acts in direct proportion to the dose given (i.e., its dilution) to the patient—has so far gained ground that efforts have been made to invent apparatus capable of controlling the dilution. It remains as a question yet to be determined what percentage vapour is a safe one. In the elaborate report[5] presented by the committee appointed by the British Medical Association we find evidence that from 2 to 3 per cent. is regarded as safe—a lower estimate than that previously given by SNOW and CLOVER In this report appears a research by Professor SHERRINGTON and Miss SOWTON upon the effect of various dilutions of chloroform upon the isolated mammalian heart. Their experiments appear to suggest that chloroform in certain strength has a direct toxic effect upon the heart muscle, but that long-continued action, so far from superinducing an effect from cumulation, establishes a species of toleration. In moderate doses also chloroform passes directly away from the heart muscle, when the perfusing fluid possesses a lower chloroform tension, a fact which suggests the questions—Can this drug poison the muscle without entering into chemical combination with its substance? Does it act as an antikatalysator on the ferment processes at the root of the normal functional activity of the contractile tissue of the heart? Dr. F. W. TUNNICLIFFE and Dr. O. ROSENHEIM,[6] also adopting LOCKE'S method of isolating the mammalian heart, presented interesting conclusions in a communication to the Physiological Society. Comparing their experience with that of POHL they found that practically the same quantities of the drug produced similar results in narcotised animals (POHL) and in the isolated mammalian heart and that a very narrow margin existed between the quantity of chloroform just borne in narcosis and that which stopped the heart. In their experiments with ether Dr. TUNNICLIFFE and Dr. ROSENHEIM were unable to produce any serious effects upon the heart with even as great a strength as 1 in 500. Professor E. A. SCHÄFER and Dr. H. J. SCHARLIEB have contributed a research to the same society dealing with the action of chloroform upon the heart and bloodvessels. They believe that their experiments show that it is the action of chloroform upon the inhibitory mechanism of the heart which produces syncope and that the result of perfusion of chloroform is to induce contraction and not dilatation of the vessels. That chloroform is an active protoplasm poison is now fully recognised and when an insufficient dilution occurs it seems more than probable that this toxic action comes into operation. Whether, however, long-protracted inhalation of chloroform will produce this result is unproven. Dr. Leonard G. Guthrie's very thoughtful paper,[7] in which he returns to the subject of fatty changes occurring, as he believes, in the liver after, and as a result of, the administration of chloroform, appears to support such a view especially when taken together with preceding reports supplied by Berend, Schenk, Fränkel, Bastanielli, Roth, Thiem, Fischer, Heintz, Cohn, Ballin, and others. That changes of a somewhat similar nature have occurred in the epithelium of the kidney tubules is well authenticated. An additional effect of both chloroform and ether was pointed out by Turck and in an editorial review of his work in the *Therapeutic Gazette* for June it is suggested that by depressing the vaso-motor centres the heat of the body is lowered and it is further indicated that the action of chloroform and ether upon the tissues may promote the formation of toxins causing destruction of the blood corpuscles. We are not at present prepared to accept this hypothesis and the kindred one that in a similar manner chloroform lessens the power of resistance of the tissues to bacterial invasion. The anæsthetic, if proved to have a causal result to these pathological changes, may be only the agent in so far as it depresses the general vitality of the tissues. The papers of Dr. S Crile[8] and Dr. J. Blumfeld[9] on the effects of anæsthetics in producing shock are of value Dr. Crile's careful study seems to indicate that surgical shock is the expression of exhaustion of the vaso motor centre, while collapse is due to suspension of the function of the cardiac and of the vaso-motor mechanism. That chloroform, and in large quantities even ether, may cause or increase such suspension of function appears rather to make us pause before accepting the current view that these anæsthetics protect the nervous system in proportion to the depth of the narcosis. The treatment of collapse under anæsthetics has been dealt with by Dr. Sawkins[10] in a useful paper. Morphine, by depressing the respiratory centre, is usually dangerous as a preliminary to chloroform. Strychnine, regarded by many writers (Dr. Sawkins, Dr. Vance, and others) as the most valuable drug in preventing and alleviating the symptoms of collapse, is by Dr. Crile considered useless in therapeutic and dangerous in larger doses. Much has been written upon the value of adrenalin in this connexion. Dr. Mankowski, who was the first, we believe, to point out its value as a vaso-motor stimulant, has been corroborated during the year by Dr. Crile, Dr. Vance, and others. As it is rapidly oxidised in the tissues adrenalin must be given repeatedly in small doses. Large doses are liable to stimulate the vagal inhibitory mechanism and may thus introduce a fresh peril into the situation. Dr. Vance's excellent paper[11] deals with all the reputed methods of drug treatment for anæsthetic collapse. In spite of the case recorded[12] in which bimanual compression of the heart resuscitated the patient after complete cardiac cessation, the work of Dr. Boureau and Dr. Gallet shows that both from the clinical and experimental side Prus's method offers us little promise of use in such cases. The importance of prompt and prolonged use of artificial respiration in failure of the medullary centres during collapse is exemplified in the reports given[13] where recovery took place after one and a half hours, and[14] in which last case recovery took place after one and a half hours, even when no sign of life appeared until 55 minutes after the occurrence of collapse.

[5] Report of Special Chloroform Committee, 1892-95, Brit. Med. Jour., July 18th, 1903. The committee consisted of Dr. Barr, Dr. Dudley Buxton, Professor Dunstan, F.R.S., Mr. Vernon Harcourt, F.R.S., Sir Victor Horsley, F.R.S., Dr. MacCardie, Professor Sherrington, F.R.S., and Professor Waller, F.R.S.

[6] Journal of Physiology, vol. xxix., No. 3.

Papers dealing with the preparation and management of the patient have appeared by Professor Witzel of Bonn who advocates lavage in post-anæsthetic vomiting, Dr. J. G. Clark,[15] and Dr. S. J. Kopetzky, whose experience is against the occurrence of post-ether pneumonia. A writer in *La Presse Médicale*, Sept. 16th, 1903, has drawn attention to the dangers associated with the Trendelenburg position during anæsthesia as tending to heart failure in the obese, to lung congestion and damage to atheromatous vessels. The research of Dixon and Brodie[16] deserves notice. They find that both chloroform and ether cause a slight dilatation of the pulmonary bronchi. Dr. D. H. Lingle's paper[17] in which he states that oxygen, a gas which has been proved to be so valuable in perflation of the lungs of persons in anæsthetic collapse, is capable of maintaining rhythmic beats in a strip of turtle's heart for a very long time, indeed, until the muscle disintegrates, appears to show that oxygen even if not a direct antagonist to chloroform vapour at least is capable of supporting its power of carrying on its function. We can only refer to Dr. Evelt's paper[18] which gives his method and to a practical communication on chloroform anæsthesia by Professor E. Martin[19]

Ether.

Many of the papers cited above deal with this anæsthetic as well as with chloroform, but Hofmann[20] devotes some space to the "initial anæsthesia of ether." The existence and use of this transient condition were pointed out years ago but possibly have been forgotten by many and may be useful for brief operations. In a paper by Dr. G. Morton[21] will be found a careful study of the phenomena of ether narcosis and a thoughtful study of the pupillary variations occurring under that anæsthetic. The important subject, the Body Metabolism under Ether, is treated by Dr. H. J. Pechell[22] but the conclusions arrived at are probably only tentative, as the factors of the problem are many, and the effects of one can hardly be accepted as determining results unless possibly coincidental variations due to diet, shock, and other causes are fully accounted for; indeed, Captain J. C. B. Statham, R.A.M.C.,[23] called the work of Dr Pechell in question on this account. In a contemporary[24] a curious and, we believe, unique accident is reported. Upon turning on the electric light near an ether inhaler the ether ignited, burning the patient's face.

Chloride of Ethyl and Bromide of Ethyl and their Mixtures.

Perhaps more work has been done during the past year upon these bodies than upon any other branch of anæsthetics. The papers of Dr W. J McCardie,[25] Dr. C. G. Cumston,[26] Dr Lotheisson,[27] and Dr. T. D. Luke[28] give excellent accounts of the work which has been done as well as the experience of the respective writers upon chloride of ethyl Dr. Burnet[29] advises its use as a preliminary to chloroform. Dr. Ware[30] gave his experience of 1000 cases and places the death-rate at 1 in 15,000, although other writers form an even more favourable estimate. He regards the anæsthetic as satisfactory in 95 per cent of cases. Certainly the causation of the deaths recorded by Soulier, Kocher, Slitz, and Bossart, with perhaps the exception of the first named, cannot without more evidence be assigned to the method employed. In the columns of THE LANCET also have appeared papers by Dr. T. EASTHAM (April 18th, p. 1091) on Bichloride of Methyl Ethylene ("Narcotile"), by Mr. W. FOSTER CROSS (April 25th, p. 1168), by Mr. R. H. JOCELYN SWAN (June 13th, p. 1677), by Mr. VERNON KNOWLES (August 1st, p. 323), and a letter by Mr. W. B. SECRETAN (August 15th, p. 496), on the mixture of methyl chloride with the bromide and chloride of ethyl, the so-called "somnoform" Several papers have appeared in this country—notably Dr. W. R. HUGGARD'S paper in THE LANCET of Sept. 12th, p. 745—and abroad in which chloride and bromide of ethyl are advocated as preliminary to ether and the consensus of opinion appears to be in favour of the plan. Mr. SYDNEY COLE has worked out with some care the physiological actions of somnoform and bromide of ethyl (a brief note of his research will be found in the Proceedings of the Physiological Society, May 16th). Both Professor VON WINCKEL[31] and Dr. BURCKHARDT[32] have tried SCHLEICH'S suggested mixture of ethyl chloride, chloroform, and ether but have returned to the use of chloroform as a more satisfactory anæsthetic. The general view of chloride of ethyl is in its favour for short operations. The views entertained by various writers differ as to after-effects and the best means of giving the drug, some referring to it as being free from all unpleasant sequelæ, others giving vomiting and headache as frequent results. We must clearly wait for further experience before deciding upon the merits of the body as a rival to nitrous oxide gas; we also require further trustworthy work upon the physiological side.

Local Anæsthesia.

Dr STRUTHERS[33] (Leith) has during the year employed OBERST'S method of local analgesia with success, limiting its use to minor operations on the digits. It should be remembered that although OBERST employed cocaine the β-eucaine may be substituted. This method is one closely resembling that of CORNING: the circulation is stopped and the anæsthetic is injected into the tissues but not into the nerve sheaths, as practised by SCHLEICH. The obvious objection to this method when it is desired to render analgesic areas the circulation of which cannot be checked is met in Mr. A. E. BARKER'S method,[34] in which the region is made ischæmic by the employment of adrenalin. He adopts a solution made as follows: β eucaine, 0·2 gramme; sodium chloride, 0·8 gramme in 100 cubic centimetres of boiled sterilised water; and 0·001 gramme of adrenalin chloride. This gives 1 in 500 eucaine and 1 in 100,000 adrenalin chloride. After 20 minutes the area into which the solution is injected becomes blanched and analgesic and is said to remain insensitive for two hours. Mr. BARKER has performed such operations as BASSINI'S for radical cure of hernia, the relief of varicose veins, and so on, and in the majority of cases without discomfort to the patient.

Subarachnoid Cocainisation.

Dr. ERNEST G. MARK has contributed a useful paper on the Present State of Spinal Subarachnoid Cocainisation.[35] He has collected 2000 European cases with six deaths, recorded by TUFFIER, GORLAD, JONNESCO, DUMONT, JULLIARD, and HEUMBERG (each one death), the last-named being due to the puncture of the spinal veins in the cauda equina. Dr. MARK, who is an enthusiast for the method, doubts whether all the deaths reported were in fact due to cocaine intoxication. In America one death occurred in MORTON'S practice but Dr. MARK doubts whether it was due to cocaine GUMPECHT reports 17 deaths following upon lumbar puncture for diagnostic purposes from the practices of QUINCKE, FURBRINGER, LENHARTZ, LICHTHEISEN, KRONIG, BULL, and GUMPECHT himself. MORTON regards these as due to shock, that is, to disturbance of the vital centres owing to the withdrawal of spinal fluid. In response to inquiries Dr. MARK finds many surgeons still use the method. He expresses a personal inclination in favour of tropacocaine instead of cocaine, eucaine or β-eucaine being unsuitable for spinal injection. ZOZLOWSKI'S method, the aim of which is to obviate the irritant action of the cocaine in water solution by employing tropacocaine in lieu of cocaine and dissolving it in cerebro spinal fluid freshly removed from the subarachnoid space, has been adopted with satisfactory results by GUINARD[36] and appears an advance in the method of subarachnoid cocainisation—a method which most observers seem to regard as a somewhat hazardous procedure and one only justified in the most exceptional cases. The plan advocated by BLOS and originated by SCHNEIDEREIN of injecting morphine with scopolamine has upon fairly extensive trial been found wanting. SCHICKLBERGER[37] has made some careful observations upon this method. It consists in injections of one centigramme of morphine and 1·2 milligrammes of scopolamine hydrochlorate four, two, and one and a half hours before the operation. Even in sleep so much restlessness was present as to interfere with the surgeon. BLOS admits that a preliminary trial in each case is necessary and WILD[38] has met with grave symptoms. In one case the patient's life was for a time threatened, while in the large proportion of his cases he had finally to resort to ether to obtain a sufficient restful narcosis for surgical procedure.

In conclusion we may note that the year has produced much that is valuable and has advanced our knowledge of both the theory and the practice of anæsthesia.

THE MIRROR OF HOSPITAL PRACTICE.

Among the numerous cases appearing in the Mirror of Hospital Practice there have been many of exceptional interest.

Post-operative Dilatation of the Stomach.

Post-operative dilatation of the stomach in any marked extent is decidedly rare though it is not improbable that some slight degree of this condition is of fairly common occurrence when an operation wound becomes infected. The presence of gastric dilatation may account for the benefit which results from washing out the stomach in some cases in which distension and vomiting occur after operations on the abdomen. An example of very marked dilatation of the stomach and intestines occurred at St. Thomas's Hospital in a patient under the care of Dr. C. R. BOX and Mr. W. H. BATTLE The patient, a woman, was admitted for the removal of a large ovarian tumour. A few days after the operation an abscess developed in the left iliac region, superficial to the aponeurosis of the external oblique. The abdomen became greatly distended and the gastric dilatation was so great that it reached down to the level of the iliac crests. By gastric lavage, hypodermic injections of strychnine, positional treatment, and the application of electricity she gradually improved, though many adverse symptoms appeared. There can be no doubt that the rapid and extreme dilatation of the stomach was due to the infection of the wound and was brought about by the action of toxins. Another somewhat similar case was reported from the Kent County Asylum where the patient was under the care of Dr. F. W. STEWART. A man, 55 years of age, suffering from epilepsy, developed an acute ischio-rectal abscess; this was opened and scraped and for ten days all went well. Then he complained of severe abdominal pain and the abdomen began to enlarge and in spite of treatment he died two days later. At the necropsy it was found that the stomach would hold 10½ pints, the walls being very thin and pale. In this case it is probable that the acute dilatation of the stomach was etiologically connected with the microbic infection of the perineum.

Chylous Ascites.

An example of the very rare condition chylous ascites was admitted into the Manchester Union Hospital under the care of Mr. ARTHUR H. BURGESS. In all 27 pints of a milky fluid were removed from the peritoneal cavity. The patient died and at the necropsy a carcinoma was found, starting in the head of the pancreas and involving the commencement of the thoracic duct and a small portion of the wall of the inferior vena cava

Strangulated Hernia in association with Hæmorrhagic Pancreatitis.

The association of a strangulated hernia and acute hæmorrhagic pancreatitis must be very rare. Such a case was under the care of Mr. W. H. BROWN in the Leeds Infirmary. The patient was a man, 60 years of age, who was admitted for severe pain in the lower part of the abdomen with vomiting and constipation. On the right side was an irreducible inguinal hernia and this was operated on, the bowel being found deeply congested but not gangrenous. The intestine was returned but the patient died 24 hours later, the vomiting persisting to the end. At the post-mortem examination the head of the pancreas was seen to be very dark in colour and friable and on its upper surface was a greyish slough. In the lesser sac was a large quantity of curdy fluid resembling pus and the foramen of Winslow was closed.

Ulcerative Colitis.

Ulcerative colitis, not dysenteric in origin, is certainly rare and therefore a case in the Great Northern Central Hospital under the care of Dr. H. W. SYERS is of interest. The patient was a married woman, 29 years of age, who about a month before admission began to suffer from troublesome diarrhœa accompanied by loss of flesh and strength. The diarrhœa continued in the hospital and about three weeks after admission she was suddenly attacked with a great increase of abdominal pain, perforation having occurred. She died a week later. At the necropsy the large intestine was found to be extensively ulcerated and in the ascending colon was a perforation.

"Trifid" Stomach.

The hour-glass stomach is now known to be by no means so great a rarity as was at one time imagined, but a stomach with a double constriction, a "trifid" stomach, is certainly extremely rare. The first example of this condition seems to have been described by Mr. A. W. MAYO ROBSON and the second was under the care of Mr. B. G. A. MOYNIHAN in Leeds General Infirmary. The patient was a woman, 27 years of age, who nine years previously had apparently suffered from a gastric ulcer with pain after food and vomiting. Similar attacks had occurred at intervals and she suffered constantly from "indigestion." A diagnosis of hour-glass stomach was made and when the abdomen was opened it was found that two constrictions of the stomach were present. Gastro-gastrostomy was performed between the first and second sacs, the second pouch was united to the jejunum by a posterior gastro-enterostomy, and the constriction between the second and the third pouches was digitally dilated. The patient's recovery was without incident.

Ectopic Gestation.

It is very rare to meet with a twin pregnancy in which one fœtus is in the uterine cavity while the other is ectopically situated. An instance of this rare association has been under the care of Dr. JOHN H. GALTON in the Norwood Cottage Hospital. Rupture of the ectopic gestation apparently occurred about the fourteenth week. A laparotomy was performed and the ectopic fœtus was removed with much blood clot. The patient died six days after the operation.

Dr. D. LLOYD ROBERTS had a case in St. Mary's Hospital, Manchester, in which ectopic gestation occurred. By abdominal section the ruptured right tube was removed with the ovary and the fœtus. Attached to the left tube was found a small firm tumour about one and a quarter inches long; this was taken away and on examination it was discovered to contain bone, cartilage, and some substance apparently epithelial. The mass was probably a dermoid cyst.

Purulent Pneumococcic Arthritis in Children.

The pneumococcus is now known to be responsible for many conditions other than lobar pneumonia, and an important series of five cases has been published in THE LANCET. These all occurred at the East London Hospital for Children and in each of them there was a purulent arthritis due to the action of the pneumococcus. In four of the cases the patients were infants and Mr. L. S. DUDGEON and Dr. W. P. S. BRANSON, who report the cases, maintain that the infective arthritis of infants is practically always pneumococcic in origin. Three out of the five patients died but the average mortality is probably less than this. In one of the cases the heart's blood contained the pneumococcus at the necropsy, and therefore it may be said that the child died from pneumococcic septicæmia.

Toothplate in the Œsophagus.

The removal of a toothplate impacted in the œsophagus is often a matter of great difficulty. Mr. W. G. SPENCER had a patient in Westminster Hospital who had persisted in wearing a broken denture. During a meal it passed into the œsophagus and there became fixed. The plate could be grasped by forceps but could not be removed. The œsophagus was opened a short distance below the cricoid cartilage and the plate was easily extracted. The wound had almost healed when the patient left the hospital three weeks after the operation.

CHEMISTRY.

Radium.

The study of radio-activity has this year passed from a seeming importance to a very real importance which, indeed, it is difficult to estimate. Chemists who have been pursuing this line of study for years have been looked upon as merely men who were groping very much in the dark but who occasionally brought to light a phenomenon pleasing to the eye and, at most, curious. The past year, however, has witnessed perhaps the most wonderful revelation that has ever been made in chemical science. It was triumph enough to discover what lay at the root of the property of radio-activity of certain minerals, but that an element would ultimately be isolated which was not only powerfully radio-active but which maintained itself constantly at a temperature above that of its environment exceeded the wildest speculation. The discovery of radium, in fact, has brought us to a very critical period in the history of scientific thought. The discovery has attracted the students of one and all branches of science, for its remarkable properties have a widespread concern. What branch of science is not concerned with a discovery, such as this, which is calculated to throw light on the origin, constitution, and destiny of matter? Time was when the atom was regarded as the smallest conceivable particle of matter. Now we know that the atom is in itself a tiny cosmos swarming with electrified particles travelling freely with immense speed in all directions, and these particles—electrons—may either manifest themselves as matter or force. We thus come back to the conception of a primordial material, sometimes force, sometimes matter, a material which perhaps is common to, and is the root substance of all the many varied forms of elementary matter known to us. The discovery of radium would thus appear to have broken down the theory so long and so tenaciously held of the immutability of the forms of matter. Already in the disappearance of the emanations from radium helium has been seen to take their place, a transformation apparently directly from a manifestation of energy into matter. All things are unstable and in a state of change: it is only a matter of time. We know of the great tendency of complex substances in the organic world to break down into simpler substances, but until the discovery of radium we had little proof that similar changes were going on in the inorganic world—a decay represented by the gradual resolution of elements of higher atomic weight into elements of a lower atomic weight. We thus gain some insight into the meaning of the distribution of rare elements and of those that are of common occurrence. It is strange that the old alchemists conceived the idea of converting metals of low atomic weight into metals of high atomic weight, thus reversing the natural tendency of the noble metals to depreciate into the baser. No wonder that the study of radioactivity which has led to the discovery of radium has excited an eager expectation amongst scientific men as to the possibility of some of the great truths and mysteries of nature being soon laid bare. Full of theoretical interest as the discovery of radium is, its remarkable property of radio activity has already met with practical application in the treatment of disease, but its real value in this regard, as in the treatment of cancer and lupus, cannot yet be determined. The radio-emanations are undoubtedly powerful to produce chemical change but it remains to be seen whether they will be effective in checking the advance of a morbid process or of destroying, or of restoring to a healthy state, diseased tissue Of the year 1903 it may be said that it was in that period that chemistry achieved one of its greatest triumphs.

Low Temperature and Biological Problems.

As with the abstruse search after radio-active bodies, so with the study of excessively low temperatures. What could be the utility of gaining low temperatures except from a purely theoretical point of view? Yet what appeared at first sight to be a study confined to mere theoretical considerations has already proved to be a source of light in biological problems and to add materially to our knowledge of the nature of disease. Thus by the application of low temperatures a mechanical trituration of every variety of cell *per se* has been accomplished and the fresh cell plasma has been obtained for the purpose of experiment. In this way moulds, yeasts, and bacteria have been reduced to a brittle state, have been crushed, and their respective cell juices have been obtained for examination. In this way the typhoid organism has been crushed and within itself has been found a toxin. We have thus to distinguish between the toxin within the cell and a toxin which is extracellular. This line of investigation is obviously calculated to help considerably in gaining an insight into the nature of disease and in discovering means by which disease may be checked or prevented.

Inorganic Ferments.

Even the distinction between an organised and an unorganised body threatens to be broken down, for a remarkable analogy has been shown to exist between the action of enzymes and of metals in the colloidal state, and so much so as to have given rise to the description of the latter as inorganic ferments. The question has actually been asked, "Are the metals living entities?" the answer to which must obviously turn on the other question, 'What is life?" If the metals platinum, gold, silver, cadmium, and iridium are reduced to such a fine state of division that they remain suspended in water in the form of a solution, that is of a colloidal solution, they bring about changes when in contact with other substances which closely resemble the changes due to the action of an enzyme. Thus platinum will oxidise alcohol to acetic acid and iridium will decompose calcium formate into calcium carbonate, carbon dioxide, and hydrogen in the same way as do certain organisms. Again, colloidal solutions of the metals will invert cane sugar and also will decompose peroxide of hydrogen after the manner of the enzymes in the blood. Most remarkable of all is that this action of metals in colloidal solution is retarded by the presence of strong poisons, such as corrosive sublimate, or sulphuretted hydrogen, or of antiseptics such as iodine. As regards the explanation of this action we are at present limited to saying that finely divided metals in the colloidal state present enormously developed surfaces and that the same condition exists in the enzyme. It is said to be catalytic action, but what is catalysis?

Food Synthesis.

The food of man is, after all, but a product of synthesis the secret of which is in nature's keeping. We know perfectly well what are the elements of food but we cannot build them up to make the concrete form—that is the function of the plant and of the animal. The synthesis of food, however, is not such a remote possibility as may be imagined, for already certain food substances have been successfully built up from their elements, but it must be admitted by laborious and expensive methods which are of interest only so far theoretically and not practically. Electricity will probably prove to be a powerful synthetic agent in the future. It has already been stated that given carbon, hydrogen, and oxygen in the simple association existing in carbonic acid gas and water the current under certain conditions will bring about a rearrangement of the elements until at length carbohydrates are obtained. This achievement, however, leaves out the question of building up nitrogenous and fatty material in a similar way. The air may ultimately prove to be a profitable source of nitrogen and already by means of electricity nitrate has been prepared from it with which to fertilise the soil for plant life. It would be a strange solution of the food problem if it should prove that all that is necessary for building up all classes of reparative materials is an abundant supply of chalk, air, and water.

THE NAVAL AND MILITARY MEDICAL SERVICES.

Exceptional Features of the late War.

Considering how much the events and changes brought about in 1903 in the army and navy have been attributable to, or influenced by, the late war in South Africa, it may be well before the subject is relegated to things of the past to recapitulate a few points connected with that campaign which well deserve to be borne in mind. The war was unique, the conditions being new, quite exceptional, and such as may, and probably will, never occur again. The scene of warfare was 6000 or 7000 miles distant from this country and the force in South Africa was about four times that which had been contemplated. The medical service which, after the Egyptian war, had been greatly reduced, was only organised for 70,000 and found itself required to meet the needs of over 200,000, and the forces in South Africa were widely dispersed and separated by long distances in a difficult country where enteric fever may be said to be endemic.

Mortality Statistics of the late War.

An exhaustive paper on the Mortality Experience of the Imperial Forces during the War in South Africa—October, 1899, to May, 1902—communicated to the Institute of Actuaries by Messrs. F. SCHOOLING, F.I.A., and E. A. RUSHER, F.I.A., has been lately published. From this we learn that the annual death-rate in the late campaign was 38 7 per 1000, as compared with 50 per 1000 the average of a number of campaigns and 70 per 1000 in the American civil war. The deaths from disease were double the number of those from wounds. In the American civil war, from 1861 to 1865, the death-rate from disease was four times that from wounds. The publication of the official narrative of the medical, surgical, and sanitary history of the war in South Africa, which is understood to be in preparation, is awaited with much interest.

1903 an Eventful Year.

The year 1903 has been full of events having a wide and important bearing upon all that concerns the defence of the empire and it has quite recently witnessed the publication of one of the most important State documents that has ever appeared in this country—namely, the Report of the Royal Commission on the Preparations for the War in South Africa, further reference to which will be made. The changes which have taken place in our public medical services it must be remembered might, but for that war, have never been undertaken at all. Their consideration would, in all probability, have been deferred on political grounds to some more fitting opportunity, to be carried out only under the pressure of some disaster or other. A glance through the pages of THE LANCET for 1903 will show that an unusually large number of questions have arisen during the past year which have a more or less direct bearing upon the maintenance of the numerical strength, health, and efficiency of our Imperial forces. The fact of the empire having just passed through a war of a magnitude such as it has not experienced for about half a century gave ample cause for reflection and we may invite attention to the thoughtful and instructive introductory address delivered by Dr. V. WARREN LOW at St. Mary's Hospital on Oct. 1st on the Relationship of the Military Medical Service to the Civil Profession.[1] The subject with which our readers are primarily and more immediately interested, however, is as to the changes which have been effected in the public medical services. As the events in South Africa were the origin and cause of these changes it was only to be expected that a beginning would be made with the Army Medical Service.

The Royal Army Medical Corps.

Following the report of Mr. BRODRICK'S War Office committee the Royal Warrant of March, 1902, for that service was published together with some new regulations which were but supplementary and complementary of that warrant. During 1903 a great deal has taken place to give effect to the reorganisation and the reforms that had been recommended and adopted, with a result which seems so far eminently satisfactory, if we may judge from the largely increased number of medical candidates who have been attracted to the service. We consequently see no reason for altering or modifying the good opinion which we expressed regarding the warrant. We said at the time of its appearance that, speaking generally, it was based upon sound lines and principles, that it introduced many new features which were urgently required, and that, taken as a whole, we thought the War Minister, the medical service, and the profession generally were to be congratulated on its appearance. We may refer our readers to the article[2] setting forth, for the information of intending candidates, the advantages introduced by the Royal Warrant. There are still several matters connected with the army, army hygiene, and the hospital service in time of war, as well as with the improvement and modernisation of many of our existing station hospitals, that need to be carefully and practically considered with a view to medical and sanitary efficiency. But as regards the Royal Army Medical Corps, what it now appears to want is rather systematic and progressive development on existing lines than any further revolutionary or organic changes. The door has been opened to professional merit and the medical officer is the master of his fate in a way and to an extent that has never before been the case. The establishment of an Army Medical College in London we regard as a very important step if for no other reason than that, in addition to the special information they are acquiring inside that institution, it places army medical officers in a position to avail themselves of all that is going on in the medical and scientific world outside it, and as an indication of the fresh spirit which has been infused into the department we may point to the issue, in realisation of a hope of many years, of the *Journal of the Royal Army Medical Corps* in July last.

The New Naval Medical Service Regulations.

Although it was but natural that in the circumstances the remodelling and improvement of the Army Medical Service should stand first in chronological order it necessarily involved that corresponding changes would have to be made in the medical service of the Royal Navy. New regulations were accordingly issued for that service and formed the subject of a leading article in THE LANCET of April 26th, 1902, p. 1193, and of some subsequent articles. In 1903 we were enabled to indicate in our Students' Number that such changes were imminent in the regulations for the Naval Medical Service as would, in our opinion, considerably improve the position of the naval medical officers. The latest regulations, in which are embodied the provisions of the Order in Council of March 24th, 1902, and August 11th, 1903, were published in THE LANCET of Sept. 12th last (*vide* pp. 774–776). This official document is of a long and elaborate description which requires to be read *in extenso* by those who intend to throw in their lot with that branch of the public service; but we may say that, speaking generally, the new regulations are regarded as satisfactory and that as far as was possible where so many differences exist between the naval and military medical services very much the same measures have been applied to both.

Indian Medical Service.

At the time of the publication of the Students' Number of THE LANCET in September last no fresh warrant for the Indian Medical Service had made its appearance, although it was, of course, well known that one had long been under contemplation and consideration at the India Office and that it might be expected to be issued shortly. That the Indian Medical Service was at the time labouring under several disadvantages and that its medical officers had some just grievances which called for notice and redress we could not doubt, and we entered into and discussed the nature of these, calling attention at the same time to a report issued by the Royal Naval and Medical Committee of the British Medical Association (*vide* THE LANCET, Sept 5th, p. 727); the Indian Medical Service has, as our readers know, always been held in high repute and esteem by the profession at large.

A memorandum showing the alterations to be effected in the conditions of the service was forwarded to us from the India Office and appeared in THE LANCET of Oct 3rd last (*vide* p 973). This was followed by the publication of a new Royal Warrant for the Indian Medical Service in the *London Gazette* of Dec. 4th embodying these alterations (*vide* THE LANCET, Dec. 12th, 1903, p. 1682). That it improves the pay and position of medical officers and largely remedies some of the evils we had referred to may well be admitted, but we are still somewhat doubtful whether sufficient has been done to restore completely the confidence of the medical profession.

The reader's attention may be directed to the address recently delivered to the students of the Royal College of

Surgeons in Ireland by Sir Lambert H. Ormsby, President of the College, published in The Lancet of Nov. 21st (p. 1413) for much useful information regarding the naval and military medical services and the present and prospective advantages which, in Sir Lambert Ormsby's opinion, these respectively hold out as a career in comparison with other sources of professional employment.

The Report of the Royal Commission on the late War.

In August and September last[3] the findings of the Royal Commissioners upon the preparations for the war in South Africa came under review together with the highly interesting and instructive minutes of evidence accompanying their report. Although the Commissioners stated that as the care and treatment of the sick and wounded in the South African campaign had been already reported upon by the Hospitals Commission of 1900 they saw no good reason for reopening that general question they nevertheless took much evidence and instituted a good deal of inquiry into these matters and into the *personnel* and equipment, organisation, and training of the Royal Army Medical Corps as well as into the army hospital system and that of army sanitation in the field. The report and minutes of evidence have a very wide and important bearing and form a mine of highly valuable and instructive information. We should hesitate to express anything so obviously true as that the first essential element in war is preparedness if every line in these official volumes did not show that this fact had apparently been altogether lost sight of in the late war. As to the skill of the army surgeons and the quality of the equipment the views expressed by the witnesses were somewhat divergent, but it is satisfactory to note that the testimony as to the personal zeal and devotion of the medical officers was unanimous. As regards the professional training of medical officers the fundamental difficulty is to make that training so far as possible of a practical character and to keep it at the proper standard throughout the medical officers' service career. Actual experience in the application of medical and surgical methods has a value of its own compared with which other things are of relatively little importance to the individual or to the State. If there is one subject more than another that requires to be put on a satisfactory basis it is army sanitation in the field and the sooner the requisite organisation for doing this is considered and settled the better. We are bound to hear a good deal more about the report of this Royal Commission when Parliament opens.

The Typhoid Fever of Armies.

As might have been expected, the etiology, causes, and prevention of typhoid fever in armies have continued to be the subject of keen investigation during 1903. A large mass of evidence as to the cause and spread of this fever in armies was published by the Government of the United States in a report on the epidemics which devastated the volunteer camps of the United States army in 1898. This was followed by the report embodying the results of the work of Lieutenant-Colonel R. H. Firth, R.A.M.C., and Major W. H. Horrocks, R.A.M.C., in the Netley laboratory. Taking the two together they afford a striking confirmation of one another—of the results drawn from real service life corroborating those of recent laboratory and bacteriological inquiries. Owing to the outbreak of enteric fever on board the reformatory ship *Cornwall* having been attributed to infected blankets from South Africa[4] the subject of the spread of this fever had also acquired a new and practical interest. Dr. H. E. Leigh Canney's scheme for securing a pure water-supply is well known and this, as well as the results of Professor Koch's recent investigations into the channels of typhoid infection in the endemically infected villages along the western frontier of Germany, have been set forth in leading articles in The Lancet of Sept. 19th (p. 831) and 26th (p. 893). It will be remembered that some time ago—in August, 1900—a commission was appointed by the Secretary of State for War consisting of Colonel J. Lane Notter, R.A.M.C., late professor of military hygiene at Netley, Lieutenant-Colonel D. Bruce, R.A.M.C., and Dr. W. J. R. Simpson to investigate the circumstances connected with the occurrence of dysentery and enteric fever in the South African campaign. There was a good deal of delay in the presentation of their report to Parliament but it was published in August, 1903, and an article upon it appeared in this journal at the time.[5] The report of this commission is a valuable one. It is based upon the results of personal inspections and inquiries made by the different members in the course of their journeys of inspection at the seat of war. The commissioners were not, however, unanimous in their report and recommendations, Colonel Notter expressing his dissent on many points.

With regard to this subject of the spread of infectious disease in armies on service our readers will probably be of the same opinion as ourselves—viz., that it is essential there should be for the future a thorough organisation of an army sanitary service to meet the needs of war.

Alleged Degeneration in the National Physique.

It will be remembered that the impeachment of the national health started by Major-General Sir F. Maurice's article that appeared in the *Contemporary Review* in 1902 was followed by a memorandum from the Director-General of the Army Medical Service on the physical unfitness of men offering themselves for enlistment in the army. This memorandum was referred by the Government to the Royal College of Physicians of London and the Royal College of Surgeons of England and elicited replies from those bodies. In other directions also investigations were made, as by the Royal Commission on Physical Training (Scotland), and are still being carried on. Sir William Taylor, Director-General of the Army Medical Service, Major-General Sir F. Maurice, and Major-General H. C. Borrett quite recently gave evidence before the Committee on Physical Deterioration at one of its late meetings at the offices of the Privy Council, Whitehall. The reader will find the question frequently referred to and discussed in our pages. So far as army recruits are concerned it may be safely said that a very great deal depends upon sufficient food, healthy environment, and suitable clothing combined with early and judicious physical training. The army being recruited from the people the remarks upon the alleged physical deterioration of the working classes made under the heading of Public Health have a direct military bearing.

Sleeping Sickness.

Our remarks would be very incomplete if we concluded them without some reference to the recent scientific labours of Lieutenant-Colonel D. Bruce, R.A.M.C., Dr. D. N. Nabarro, and Captain E. D. W. Greig, I.M.S., F.R.S., in regard to this disease and to its being caused by the entrance into the blood and cerebro-spinal fluid of a species of trypanosoma parasite, as set forth in the "further report" of the Sleeping Sickness Commission recently published by the Royal Society and to which we refer in another column.

We may well close this section of our annual summary by congratulating Brevet Colonel Bruce on his well-earned promotion in recognition of his distinguished scientific services in connexion with his discoveries regarding the causes of Malta fever and of sleeping sickness.

PUBLIC HEALTH.

Although the year 1903 will not stand out in the history of public health as having been associated with any signal discoveries as regards European diseases it will nevertheless be marked chronologically as one in which material advances have been made in certain directions and in which subjects of very far-reaching importance have come into prominence. Taking a broad view of our subject matter it will, we think, be conceded by all epidemiologists that the most startling theme of discussion from a public health standpoint has been that which has had concern with the alleged deterioration of our national physique, a subject which has filled many pages of our leading monthly reviews and which has led to the appointment of yet another committee.

Physical Deterioration of the Working Classes

The alleged physical deterioration of the working classes amounts to an impeachment of preventive medicine of a somewhat serious character. If it were true that notwithstanding the better housing of the people, the limitation of the hours of labour, the improved conditions under which factory and other work in carried on, the greater purity of the water which the people drink, of the food which they consume, and of the soil upon which they live, physical degeneration was proceeding apace, the whole policy of our public health administration and of our social conditions generally would need to be committed to the melting pot of searching criticism Fortunately, however, the grounds upon which the allegation is based are not such as to call for an investigation of so radical a nature, and it would appear to be not improbable that erroneous inferences have been drawn from the fact that a large proportion of the men who present themselves for enrolment in the army are from one cause or another unfitted to undertake the necessary duties and that many of those who are actually enlisted are unable, after two or three years, to meet the physical demands which are made upon their strength. It is, of course, conceivable that, in consequence of improvident marriages contracted among the "unfit," of the abstention from child-bearing on the part of the "fit," and of the increasing urban conditions under which the people live, physical decay is commencing and, as was insisted upon in the last Huxley lecture, there is need for more control and selection in the matter of reproduction. But this multiplication of the so-called "unfit" has gone on in all generations and it is going on to day among every nation of the world. If the principles and practices of the stock-breeder and pigeon-fancier are to enter into human affairs we must endeavour to discover some means by which the reproduction of the Mongolian, the Hindoo, and the negro may be checked while that of the European may be encouraged.

In so far, however, as this country is concerned it appears that the most probable explanation of the alleged deterioration of the working classes is based upon a misconception of the facts and that, on the contrary, what we are witnessing may be merely one of the effects of the improved well-being of the people and of the greater attractions offered to the worker by civil employment If this be so the recruiting sergeant is really carrying on his work in a lower social stratum in which, by the force of circumstances, the proportion of the unfit is greater than was the case when he was appealing largely to a relatively better class. It is, too, conceivable that, although the fact is not recognised, a somewhat higher standard as regards fitness may now quite unconsciously be set and that, perhaps, more stress than formerly is being laid upon defective teeth, imperfect vision, and the like.

The circumstances which give us pause are reports such as that upon "Poverty: a Study of Town Life," by Mr. B. S. Rowntree, and that by Mr. Charles Booth upon the "Life and Labour of the People of London." It is, however, very difficult to reconcile the alleged deterioration of the masses with the statistical testimony, afforded by the life tables of our large cities, as to the increased expectation of life at nearly all ages, although we quite recognise that increased longevity does not necessarily imply increased vigour It is obviously possible by adopting certain artificial conditions of living and by protecting the people against the forces which hitherto thinned their ranks to rear up a people who might at once succumb were the pristine conditions as regards environment to be reverted to. To take plants from the rigour of the outside elements and to place them in a well-regulated conservatory is not an act calculated to improve the natural vigour of the stock. But it might be contended by visionaries that our life tables hold out some hope that we may by our public health measures be approaching that "physiological old age and normal death," the advent of which Metchnikoff describes so eloquently in his remarkable work on "The Nature of Man" If that time ever arrives death will have no terrors, because man will then have evolved what Metchnikoff terms "the instinct of death," which he will embrace as eagerly as in youth he accepts the instincts of love and reproduction.

Some of these considerations will perhaps be dealt with by the committee above referred to, although it is hardly likely to inquire into what may be termed the evolutionary aspects of the problem. There is certainly need, however, that a wider view should be taken of public health than has hitherto been the case and we are interested to see that some medical officers of health are beginning to appreciate this point. We find some, for instance, speculating upon the disasters likely to accrue from the limitation of reproduction on the part of those whose types are well worthy of being perpetuated, while others are drawing attention to the effect of alcoholism in the direction of promoting tuberculosis. Some, too, are evidently anxious to re-awaken a crusade against venereal disease. But reflections such as these bring us to the second question which has bulked largely in medical and lay literature during the past year.

Pulmonary Tuberculosis.

The subject of pulmonary tuberculosis seems by virtue of its excessive incidence upon the poor and unfit to follow naturally upon the foregoing remarks. In the first number of The Lancet for 1903 we were able to publish the prize essays in connexion with the King's Sanatorium and in our later issues we have had the satisfaction of recording the laying of the foundation-stone by His Majesty. This institution, which is being raised amid almost ideal surroundings, cannot fail to prove a lasting boon to those tuberculous subjects who occupy a station of life above that of the poor but who cannot afford the charges demanded at those private institutions at which their more fortunate fellow sufferers are able to give themselves every opportunity of continuing their labours. In the spring of the year the Milroy lectures upon Pulmonary Tuberculosis were delivered by Dr. H Timbrell Bulstrode before the Royal College of Physicians of London and these, which we published subsequently in our columns, should aid in steadying public and professional opinion upon some of the problems involved in dealing with this widespread malady. The lectures dealt largely with the epidemiological aspects of the problem and they showed how markedly the disease is declining in this and many other countries in consequence, apparently, of general hygienic measures and the improved social conditions of the people. They furnished, too, abundant evidence showing that the communicability of the disease is but slight and that to rank it *quâ* infection with the acute exanthemata is, as we have for a long time held, an altogether distorted view to take of the situation.

The Royal Commission which is considering the relation of bovine to human tuberculosis has not yet reported but during the year numerous experiments have been conducted in this country and elsewhere which tend to show that the results obtained by KOCH and SCHUTZ are not constant accompaniments of experiments of this nature. Human tuberculosis is obviously transmissible to bovines in certain circumstances and it remains for the Royal Commission to tell us with what facility, if at all, bovine tuberculosis is transmissible to the human adult or infant. But in the meantime there has come over from Germany a pronouncement from BEHRING which is almost as startling as was that made in 1901 by KOCH and which is, moreover, its almost direct antithesis. BEHRING and his pupils have performed a series of experiments which they claim tend to show that the intestinal tract of young animals and, inferentially, of infants is of such permeability as to allow organisms to pass through with far greater facility than is the case with adults, and, briefly stated, BEHRING's thesis is to the effect that the bacillus of tuberculosis is acquired during infancy and that the disease remains potential until the environment or circumstances of the host enable the parasite to multiply and to produce the active disease known as tuberculosis. In support of his thesis BEHRING refers to the widespread presence of tuberculosis as evidenced by post-mortem examinations, and more especially does he lay stress upon the figures published by NAEGELI who claims to have found signs of tuberculosis in the bodies of all persons over 30 years of age. BEHRING also apparently draws attention to the alleged fact that no fewer than 68 per cent. of the men of an Austrian regiment who were inoculated with tuberculin reacted thereto. In BEHRING's view the communicability of pulmonary tuberculosis from person to person has not been satisfactorily demonstrated and he would presumably explain instances of alleged infection by the thesis that persons thought to have been infected were living in circumstances which rendered them susceptible to the parasites which they had harboured since their early infancy. BEHRING has also been endeavouring to discover a method of preventive inoculation against tuberculosis in order that sanatoriums and other direct measures may not in future be required. In Paris we hear of Dr. MARMOREK resigning his post at the Pasteur Institute in order the more fully to pursue his investigations relating to what he regards as the true toxin of the tubercle bacillus. From the antitoxin which he procured from a horse treated with this toxin Dr. MARMOREK hopes to be able to establish a serum treatment of tuberculosis. The latest news from Paris is not, however, by any means encouraging.

As regards other preventive measures taken during 1903 we may add that the voluntary notification of pulmonary tuberculosis has been adopted by additional sanitary authorities and that Sheffield has, under a local Act, succeeded in obtaining powers from Parliament to render it compulsorily notifiable. It is, however, important to point out that this disease is not added to those comprised in the Notification Act and that the subjects of pulmonary tuberculosis are expressly exempted from the disabilities imposed upon those suffering from the acute exanthemata. It is this difference of treatment for which we have already contended in our columns. Much progress has been made in the erection of public sanatoriums. Cumberland is erecting an institution near Keswick; the three counties of Gloucestershire, Somersetshire, and Wiltshire are providing a similar institution at Winsley near Bath, while Devonshire, with Cornwall, has secured a building at Brent. In a recent issue we drew attention to a new departure as regards district councils and sanatoriums, and in a leading article in THE LANCET of Nov. 21st, p. 1444, we discussed the proposal to convert one of the Metropolitan Asylums Board fever hospitals into a sanatorium. The Board has decided that a step of this nature would form such a far-reaching departure that it must ask for an expression of opinion on the part of the Local Government Board. Mr. LONG will doubtless go very thoroughly into the question.

The Control of Midwives.

The reduction of the mortality both of mothers and infants which is consequent upon complications of childbirth is a matter which clearly comes within the province of preventive medicine; therefore any progress made in the administration of the Midwives Act of 1902, which came into force on April 1st of the year under review, is, assuming always that the Act is a good one, a matter for congratulation.

Up to the present, however, attention has been directed mainly to the formation of the Central Midwives Board and to the framing of rules by such Board. The local supervising authorities have not been idle and there are indications that the county councils and county borough councils throughout the country are seriously setting to work to make the best they can of the measure. It would seem that there is practically unanimous agreement among county councils not to delegate their powers to the local district councils, and in cases where a county medical officer of health has been appointed administration by a committee of the county council would appear to offer the best chances of success, at any rate in the first instance. But in counties where there is no such medical officer of health questions may arise of appointing a medical officer *ad hoc* or of delegating the powers to local authorities with expert advice at their disposal.

The measures which are now being taken for the control of midwives may, we trust, in the future be also turned to good account in the direction of lessening what is perhaps the most serious blot upon all our preventive measures and that is the persistence of infantile diarrhœa. It is to be hoped that as there rises up a better educated class of midwives they will be able to introduce into the homes and habits of the poor better notions of that elementary cleanliness which is so inextricably bound up with the health of infants. And in this matter of the improved well-being of children the question of

Physical Training and the Teaching of Hygiene in Schools

calls for comment. This subject has received considerable notice both in the medical and the lay press during 1903 and we are glad also to note that an increasing number of medical officers of health refer to the subject in their annual reports. All will, we feel sure, agree with the report of the Royal Commission on Physical Training (Scotland) that "the education cannot be based on sound principles which neglects the training and development of the bodily powers."

In our view the teaching of elementary hygiene in our public schools, the periodical examination of the children, and a well-organised system of physical drill carried out, not in dusty schoolrooms but either outside or in special buildings, will tend to promote national physical fitness, the decline of pulmonary tuberculosis, and the improved well-being of the people to a greater extent than any special legislation directed against tuberculosis is likely to effect. In this direction the School Board for London under its medical officer's guidance is setting an example which, if expanded and followed, will merit the lasting gratitude of future generations. County councils throughout the country have now an excellent opportunity of manifesting their appreciation of the confidence which the nation has shown in them in intrusting them with the education, mental and physical, of her children.

The Control of our Foods and Drinks.

It is a matter of regret to all those interested in the better control of our food supply as regards purity and wholesomeness that the recommendations made by the Food Preservatives Committee as to the material expansion of our present machinery for controlling the preparation and preservation of foods have not yet been acted upon. A considerable time has now elapsed since the report was issued and, so far as we are aware, nothing but approval has been expressed with regard to the recommendations which it contained. But there is hope that the year 1904 will see progress in this direction. We have recently drawn attention in our columns to the exhaustive report of the Royal Commission on Arsenical Poisoning and, as our readers will have observed, the recommendations made by that Commission are very much on the same lines as those made by the Food Preservatives Committee. This being so Mr. LONG should have no difficulty whatever in framing a measure which in principle would embody the recommendations of both these bodies. The report on arsenical poisoning again accentuates the pressing need which obtains at the present time for more supervision over the processes of manufacture of food and drink. Neither the chemist nor the bacteriologist can tell us for certain of the unwholesome conditions under which certain processes are carried on, or of the, at present, largely unknown ingredients which are used in the preparation of some of our foods. The report on the purity of aerated water which was made in 1903 to the London County Council by its senior assistant medical officer of health is an opportune illustration of the dangers which obtain in the preparation of foods and drinks not subject to proper control. To ask for a demonstration of injury when the risks are so patent is in no sense preventive medicine and although in the matter of the elimination of arsenic much good work has already been voluntarily effected any appearance of slackness or want of initiation on the part of our law makers is likely to create a very erroneous conception of the true state of affairs.

The Treatment and Disposal of Sewage

The Royal Commission which is considering this subject has during 1903 issued its third report which dealt with trade effluent and the formation of a new central authority, but at present the recommendations of the Commission have not been given legislative effect. It is, we believe, probable that the Commission will shortly issue another report dealing with the steps which should be taken to put an end, so far as practicable, to the risks which at present attend the consumption of certain shell-fish, and possibly Mr. LONG is awaiting the advent of this fourth report in order to embody its recommendations in his Bill

Small pox and Vaccination.

The lesson of 1903 is such an old and oft-repeated one that reiteration of it approaches boredom but in certain particulars the year has left its records upon epidemiology. The anomalous form of small pox which appeared recently in Trinidad has now manifested itself in this country and instances of it have been seen at Cambridge and elsewhere. These "sports" of nature, if such they can be termed, teach us several things. In the first place they show us that a disease may at times present itself in such an anomalous garb as to render diagnosis extremely difficult even by experts, and in this sense the importance of the general protection of the population by vaccination and revaccination is accentuated. But such anomalous cases also point to the desirability of always treating suspicious cases as if they were small-pox and of seeing multiple cases of the prevailing ailment before venturing to deny that the disease in question may not in the end prove to be the dreaded malady. If a sufficient number of cases are seen diagnosis would present fewer difficulties.

Another year has passed and Parliament has again evaded consideration of the vaccination problem. Despite the efforts of the Imperial Vaccination League and of other bodies, and notwithstanding the greater eloquence of the presence of small pox in our midst, there is a hesitancy on the part of the legislature to face the needs of the situation and to introduce a Bill providing for general revaccination. The term "compulsion" would seem to make the modern legislator turn pale with fear and when the subject of vaccination arises in the House of Commons many of those who are ostensibly upholders of vaccination are either absent or mute. An excellent illustration of this aphasic condition was afforded in the House of Commons when Mr. CHAPLIN was introducing the present Vaccination Act. But in these days the term "compulsion" as applied to vaccination is surely a misnomer and there should be no difficulty in passing a measure which proposed to place general revaccination upon the same basis, *quâ* compulsion, as primary vaccination. But be this as it may, it devolves upon the recording angel of 1903 to write down the fact that in place of the bread of revaccination Mr. LONG has given us the stone of an inquiry into the cost of applying the present very imperfect measure.

EXOTIC AND TROPICAL DISEASES

The harvest of our knowledge with respect to tropical and other exotic diseases has been an abundant one for many years past and the record of 1903 has well maintained the average.

The International Sanitary Conference which held its inaugural meeting in Paris on Oct. 10th terminated its labours on Dec 3rd by signing the new International Convention and although certain of the smaller Powers abstained at that date from giving their formal adherence to the document it is very satisfactory to note that the Convention has already been signed by eight more Powers than has been the case with any other previous Convention. Generally speaking, the measure has to be regarded as a sort of consolidation and amendment act into which there has been introduced certain provisions and modifications justified and rendered necessary by the advance of our knowledge as to the epidemiology of plague and cholera. The two most important new departures consist, firstly, in the reduction of the period of detention of infected vessels from 12 to seven days, a concession which will be hailed with satisfaction by every shipping company and all travellers; and, secondly, the application, as regards plague, of destructive measures to rats. The destruction of these vermin in infected vessels is to be carried out as rapidly as possible before or after the cargo is unloaded and no damage to merchandise on the ship is to result from the process. This will rather tax both the ingenuity and the present resources of some of our port sanitary authorities, more especially the smaller ones. Throughout the whole Convention there breathes a very liberal spirit and much is left to the discretion of sanitary authorities. We in England have long since ceased to lose our heads when a case of exotic disease arrives at one of our ports and it is gratifying to notice that the same spirit is gradually pervading other countries. The crux of the future is to procure the intelligent coöperation of Turkey, of Eastern countries generally, and of our own colonies.

Plague

The spread of cancer and the pathology of sleeping sickness are both topics of the first interest to the sanitarian, but we have already discussed these topics, as also leprosy, under another heading. A brief allusion has been made, too, to the prevalence of plague, but this is a matter on which more may be said.

We hoped to have been able at the end of 1903 to record a diminution in the amount of plague distributed throughout the world but unhappily we are unable to do so, for in India the malady has raged more severely than in any previous year. The total cases and deaths from plague in India during 1902 were respectively 765,172 and 575 469; the figures for the period up to mid-November, 1903, reached the enormous total of upwards of a million cases and 743,000 deaths. In China the chief maritime towns have continued to suffer as well as the adjacent districts but owing to the absence of proper records it is impossible to form any approximate estimate of the extent to which the disease has spread in the Chinese empire. We know, however, that Hong-Kong, Canton, Amoy, Foochow, Shanghai, Peitang, Tientsin, Inkoü, and Newchwang have all had their local epidemics. From Hong-Kong, where alone it has been possible to get trustworthy reports, we hear that the annual epidemic has been more virulent than that of last year, notwithstanding the efforts made by the local authorities to prevent its spread. Japan with its many ports has also suffered, chiefly from imported infection, Tokio, Nagasaki, and Yokohama all yielding cases. Formosa, too, has suffered but not so much as in 1902 In the Philippines, especially in Manila, plague again made its appearance but the epidemic was of smaller proportions than in the previous year. In the Straits Settlements, Siam, French Indo-China, and New Caledonia plague has shown itself, though the outbreaks have not been of any great dimensions. In Australia plague has cropped up in various localities, as, for example, at Fremantle and Perth in Western Australia and at Brisbane, Rockhampton, Bundaberg, and Townsville in Queensland. In Sydney (New South Wales) a plague epidemic almost entirely confined to rats and mice developed in the summer. A German ship from the River Plate also arrived at Sydney in August with a large number of plague-infected rats but no extension of the infection from rat to man appears to have taken place. In the Hawaiian Islands, chiefly at Honolulu, scattered cases of plague were reported during the year. Plague has continued to occur in isolated cases at San Francisco, where up to November some 17 cases, all fatal, had been bacteriologically confirmed. The fact that only fatal cases were heard of excites some suspicion that possibly the Chinese population in San Francisco were concealing the milder cases and only allowing the evidently fatal cases to come under the observation of the sanitary authority when it was no longer possible to conceal them. From San Francisco the infection was carried by ship to Mazatlan in Mexico and from this place it extended to Ensenada and other Mexican localities. Gradually the infection was conveyed southwards to Peru, where Callao, Pisco, Mollendo, Pascamayo, and Lima yielded cases. Chile also was invaded, Iquique, Valparaiso, Pisagua, Talcahuano, and some outlying villages in the vicinity of Concepcion becoming infected by plague. Brazil, it may be remembered, was first invaded by plague in 1899 and since then has had plague outbreaks in each year. During the early months of 1903 the disease was epidemic in Rio de Janeiro with some severity and later Rio Grande do Sul was also invaded. Towards the end of the year plague was again reported to have become epidemic in Rio de Janeiro and to have also broken out at Para in Northern Brazil. No cases of plague appear to have been recognised during 1903 in Argentina, Paraguay, or Uruguay.

In South Africa plague lingers but seemingly without making much progress In Cape Colony cases of plague occurred during 1903 in isolated groups or single cases at Port Elizabeth, where rats were also infected, but there was no real epidemic. Cases, occurring also in scattered fashion, were reported at King William's Town, Graaf Reinet, East London, Grahamstown, Burghersdorp, Queenstown, and Knysna. Plague, affecting rats and mice only and also in some instances cats, was observed in the Cathcart district, at Stockerstrom, and at Riversdale. At Table Bay five cases of plague occurred on board a ship which had come from Bombay and had called at certain East African ports. In Natal plague broke out in December, 1902, and became to some extent epidemic in certain parts of the town of Durban during the spring and summer months. The infection was carried later to Maritzburg and to some outlying places in the districts of Eshowe and Inanda. The epidemic died down in the summer and no cases were reported in Durban after August. During July there were observed in the Transvaal at Johannesburg some very suspicious cases of illness with buboes, but on bacteriological authority the disease was declared to be due to a pneumococcic infection. Some suspected cases of plague were reported in Mozambique early in the year. For the fifth year in succession Mauritius suffered from a plague epidemic which was of greater severity than that of 1902.

In Algeria some suspected cases of plague occurred at Blida in September but no report on the cases has, so far as is known, been made public. In Egypt plague seems to have smouldered but never became epidemic. Only 125 cases were reported from Alexandria in a population of over 300,000. Some 33 cases were referred to Port Said and 27 to Damietta. Small groups of cases were also reported in certain of the Egyptian provinces. There was no outbreak of plague in the Mahomedan Holy Land during 1903. Some cases occurred in Assyr in Arabia which is regarded as a plague endemic area. In the Bahrein group of islands in the Persian Gulf a sharp outbreak occurred, the disease proving fatal, it is said, to upwards of 1000 of the inhabitants. Statements have also been published that plague was epidemic during the spring of 1902 in the Persian district of Hawizeh.

Notwithstanding the widespread diffusion of plague throughout the world Europe almost entirely escaped the infection. A small outbreak, however, occurred at Marseilles in September among the workers in a paper factory, the disease having been originated, it is stated, by the handling of infected rags. The precise number of attacks and deaths has not been definitely made known but it is asserted by some that at least 15 persons were attacked and that at least six of them died. Fortunately the infection was quickly subdued and no extension took place in Marseilles or from that city to any other locality. A small outbreak, comprising two cases, occurred at Berlin in June, the first person attacked being a young Austrian medical man who had been making plague cultures in the laboratory of the Berlin Infectious Diseases Institute and who had accidentally inoculated himself. He communicated the disease to one of the attendants who waited upon him during his fatal illness. A small outbreak occurred at Rhodes, comprising three cases on board a sailing vessel from Alexandria in September. There were some scattered groups of cases of plague at certain places in Syria and Asia Minor but no epidemics followed.

No known case of plague occurred in the British Islands during 1903, either indigenous or imported. Only one inland case of suspected plague was heard of during 1903 but bacteriological investigation at once disproved the diagnosis of plague. A few ships having on board single cases of illness that were thought to be possibly of the nature of plague came under the notice of port sanitary authorities during 1903 but in not a single instance was the ailment found to be plague when investigated bacterioscopically. So far as Europe is concerned 1903 must be regarded as an uneventful year as regards plague save in respect to the Convention which, as we have already said, was signed in Paris.

Cholera.

During 1903 cholera continued to manifest itself in the East with considerable virulence but fortunately did not establish a footing in Europe. At the beginning of the year the disease was fast disappearing from Egypt, where it had been raging in the latter months of 1902. Less than 100 cases of cholera occurred in Egypt during the early part of 1903, these cases being as it were the expiring embers of the 1902 conflagration which had carried off nearly 35,000 persons in Egypt. Happily, notwithstanding the grave apprehensions entertained by some persons, there was no recrudescence of cholera in Egypt or in the Mahomedan Holy Land during the summer and autumn months of 1903.

But in Syria and Palestine, where cholera had spread from Egypt late in 1902, the disease made considerable ravages and though up to midsummer upwards of 6500 cases had been officially reported this number does not represent by any means the true local incidence of the disease. Resident Europeans have furnished ample evidence of the concealment of cases not only by the natives but by the Turkish officials themselves. Cholera spreading from the south of Palestine gradually extended through the vilayet of Damascus and northwards and westwards to the vilayets of Aleppo, Adana, and Diarbekir, threatening Asia Minor and Mesopotamia. The spread of cholera from Egypt by way of Palestine and Syria to Asia Minor and Mesopotamia is most unusual. It is probable that the construction of railways in Syria and Palestine may have had some effect in determining the direction of the spread of cholera by hitherto unreported routes.

Much consternation was caused in January by the arrival at Malta of a cholera-infected British ship from Alexandria. Altogether nine cases and three deaths occurred during the passage to Malta or after detention at the Maltese quarantine station on Comino Island. After landing the sick and after disinfection had been carried out the ship sailed for the Thames, where after the usual precautions had been taken the vessel was admitted into the London Docks.

In India cholera has, as usual, displayed considerable virulence. The complete records are not yet to hand but in Bengal alone over 143,000 deaths had been certified during the first seven months of the year. Among the Europeans who suffered were 25 men of the 2nd Shropshire Regiment, of whom 17 died. The United Provinces of Agra and Oudh also lost over 30,000 of the population from cholera during the same period. In the autumn of the year Afghanistan was invaded by the disease which became epidemic in Kabul and Kandahar. In French Indo-China cholera was prevalent from March to June. Early in the year there was an outbreak at Bangkok, the capital of Siam. There were also minor outbreaks in the Straits Settlements and the Dutch East Indies. A considerable epidemic occurred in the Philippine islands, over 20,000 cases and about 15,000 deaths being reported up to the middle of September. Specific pollution of public and private water-supplies provided the means for wide and rapid diffusion of the disease. From China, although the sources of information are limited, we learn that cholera was present during 1903 at a number of important seaport towns as well as in the interior—Hong-Kong, Canton, Amoy, Shanghai, Hankow, Chefoo, Tientsin, and Peitang (at the last place it is said that 2000 deaths occurred in two months). In Japan a number of localities were invaded by cholera but no large epidemic appears to have supervened. Among the places from which cases of cholera were reported may be mentioned Nagasaki, Saga, Tokio, Fukuoka, Kobe, and Yokohama. Several cases of cholera occurred on board a Russian man-of-war while in Nagasaki harbour.

Yellow Fever.

The important revolution which has of late years taken place as regards the etiology of yellow fever and the prophylaxis of the disease and which, when fully appreciated, as at Havana, has succeeded in effectually removing the disease from the current records of mortality, gave hope that yellow fever might soon become a comparatively rare disease This hope, however, has not been realised during 1903, for there has been a somewhat severe epidemic in Mexico and other outbreaks have occurred in Brazil, Panama, Costa Rica, Venezuela, and Ecuador. In Mexico a severe outbreak has been in progress since July, the greatest sufferer being the town of Linares, which is situated 55 miles south-east of Monterey, the capital of Nuevo Leon. In this place during August, September, and October at least 1800 cases were reported. At Monterey some 500 cases have also been noted. In Vera Cruz, from June to November, 900 cases came under observation. Two British ships became infected, probably through members of the crew contracting the contagion on shore. At Tampico yellow fever was also epidemic in the autumn months, carrying off 300 persons. An outbreak of yellow fever was reported in October from Laredo, a town of about 4000 inhabitants in the State of Texas, over 1000 attacks being recorded up to the end of November. These cases occurred chiefly among Mexicans residing in the town; an outbreak occurred at Minero and some cases were also recognised at San Antonio, the largest town in Texas, about 250 miles from Galveston, and some also at Cannel. The Central Public Health Department of the United States has made great efforts to get the different republics bordering on the Mexican Gulf to adopt the same policy as to yellow fever as has been adopted at Havana with such success, but the republics in question lag far behind the United States in their public health administration. During 1903 only three cases of yellow fever were reported from Grand Bassam, on the French Ivory Coast, West Africa.

Beri-beri.

This somewhat mysterious disease has continued to excite interest in the minds of observers during 1903 Its occurrence in certain localities and in certain ships has puzzled those who have investigated its causes and there has been considerable doubt as to the nature of the malady. The recent Norwegian Commission, over which Professor UCHERMANN presided and which inquired into the subject owing to the more frequent occurrence of beri-beri on board Norwegian ships as compared with British vessels, defined beri-beri as the oriental name for a multiple neuritis due to toxin poisoning by tainted vegetable or animal food stuffs. The vegetable form more particularly corresponds to the Asiatic variety and is principally brought on by eating bad (damaged or tainted) rice. The animal form corresponds more particularly with the beri-beri of European merchant ships and is chiefly caused by the use of tainted tinned (canned or preserved) provisions.

During January, 1903, there was an epidemic of beri-beri at Panama where, it is stated, previous epidemics have occurred which have been variously attributed (1) to the consumption of certain classes of food; (2) to a specific germ producing a toxin; or (3) to disturbance of the soil and emanations therefrom. It is said that those attacked had been living under deplorable sanitary conditions and that many of the sufferers had previously suffered from malaria. During 1903 some cases of the disease were discovered in Egypt and many cases occurred in China. The Malay Peninsula is notorious for the number of cases of beri-beri which occur there and it is interesting to know that at the present time the etiology of the disease is being scientifically investigated there as well as in India by competent experts. It remains to be mentioned that ship-borne cases of beri-beri came under the notice of several of our English port sanitary authorities during the year.

The suggested relationship of beri-beri to arsenical neuritis has been discussed in its recent final report by the Royal Commission on Arsenical Poisoning but without definite conclusion, the evidence having been insufficient to establish any connexion, although in some instances traces of arsenic were found in preserved fish and other foods supplied to vessels making long voyages. It seems, however, probable that true beri-beri is altogether distinct from arsenical neuritis.

Legislative Forecast.

We venture to hope that in our next Annus Medicus we shall be able to record the promotion of the President of the Local Government Board into a Secretary of State and that the central bureau of public health will have given means (1) to amend and to consolidate the Public Health Acts;

(2) to carry into effect the recommendations of sundry commissions and committees as to the better control of our foods and drinks; and (3) to carry out the recommendations of the report of the Royal Commission on Sewage Disposal.

THE GENERAL MEDICAL COUNCIL.

The work of the General Medical Council during the past year, if we except its regular task of purging the Register of unworthy members of the profession, has centred almost entirely round the question of preliminary scientific education of the student and the attitude of certain corporations with regard to the same. At the first and regular summer session a great deal of time was taken up by penal business, none of which was of particular interest save to the persons involved. It is, however, important that the work of the Council in this direction should not be cramped. We say this because Sir WILLIAM TURNER, from the presidential chair, expressed a doubt whether the amount of money which was represented by the time occupied in the hearing of penal cases was well spent. Sir WILLIAM TURNER is an able and careful president and we do not disagree with his views, or with what are apparently his views, without feeling sure of our ground. But we are clear that nothing must be allowed to curtail the penal work of the General Medical Council, lest the Council should wear the appearance of scamping one of its most important duties or of lightly condemning medical men to professional ruin When the proper threshing out of a penal case requires time, time must be given. It is, however, an unfortunate fact that the pecuniary position of the General Medical Council makes time of particular value. Mr. ALLEN, the registrar, has estimated the expenses of the Council at £650 for a session of two days and £175 for each day that follows. The subdivision of Victoria University will enlarge the *personnel* of the Council and the resolution of the General Medical Council to make regular inspections of the examinations conducted by the various bodies also points towards a rising expenditure. A memorandum of the inadequacy of the income of the General Medical Council is now before the Financial Relations Committee which will, we suppose, soon advise the Council what steps should be taken towards the keeping down of expenses or the raising of income.

The great and serious cost of a special session was brought home to the Council this year. The unavoidable length of time occupied in the May session by the consideration of penal cases left untouched the burning question of the preliminary education of candidates for the medical profession. A special session was accordingly arranged for July 15th, the business being the consideration by the Council of the inspector's and visitor's reports upon the examination in chemistry, physics, and biology of the Conjoint Board of England and the Society of Apothecaries of London. The special meeting lasted two days and upon full debate the points at issue resolved themselves into one—viz, the expediency of exercising the power of the Council conferred upon it by Act of Parliament of reporting to the Privy Council that the course of study and examination required by the two Colleges and by the Society were insufficient. With commendable prudence it was agreed to postpone the decision until the winter session.

The winter session opened on Nov. 24th and its time, like that of the two previous sessions, was mainly occupied with the discussion of the relations of the English corporations to the central educational authority. And although in the interests of peace it is a source of gratification that no definite conclusion has been reached—for delay may mean a harmonious arrangement of difficulties—yet procrastination in this matter cannot be indefinite, for the other business of the Council is being blocked while time is spent in discussion. Undoubtedly the exact position of the General Medical Council, the central authority in medical education, towards the universities and corporations entitled to grant degrees and qualifications for medical registration is a matter of the highest importance. It is a position that ought to be made extremely definite and that is what we think it now is. The question has undergone sufficient deliberation and it is clear to us that the General Medical Council must not be checked in its work of maintaining the standard of medical education. The present position is that the Colleges are considering the subject, with the desire to remedy all defects, so that it is to be hoped that new regulations may be formulated before the meeting of the Council in May, 1904. Open rupture has been averted but the Council has shown its determination to maintain the position it has taken up, a position which we consider is completely justified We repeat this because, although we have not the slightest desire to curtail the privileges of old and dignified corporations, we consider that the position of the General Medical Council as the central authority in medical education must not be jeopardised.

BRITISH MEDICAL ASSOCIATION.

The seventy-first meeting of the British Medical Association was held at Swansea, the meeting commencing on July 28th under the presidency of Dr. THOMAS DRYSLWYN GRIFFITHS, ophthalmic surgeon to the Swansea Hospital and late physician to the Swansea Infirmary. This is the second occasion that the Association has met in Swansea, the first being 50 years ago The President took for the subject of his address the Evolution of Antiseptic Surgery and its Influence upon the Progress and Advancement of Bacteriology and Therapeutics. The Address in Medicine on Infective and Infectious Diseases was delivered by Dr. FREDERICK T. ROBERTS and the Address in Surgery on the Evolution of Abdominal Surgery was delivered by Mr. A. W. MAYO ROBSON. The first general meeting was notable for the election of H R H, the PRINCE of WALES as an honorary member of the Association. The annual dinner of the Association was held on July 30th, among the oversea guests being Professor J. G. ADAMI, Professor H. SENATOR, and Professor T. GLUCK. Although accommodation was somewhat limited owing to Swansea being a small town and to the assizes clashing with the date of meeting the gathering was generally held to be most successful. We make no attempt to summarise the proceedings of the Association because, owing to the facilities courteously offered by the executive to our representatives, we have been able to report the meeting very fully in our columns. The next meeting of the Association is sure to attract a large crowd, for the venue is Oxford, the president-elect being Dr. WILLIAM COLLIER.

VARIOUS HOSPITAL FUNDS.

Owing to the growth of the population on the one hand and the strides which medical science is making on the other, each year shows a growing demand for money to supply the needs of the sick poor and to keep pace with the improved appliances which the best medical treatment demands. It is satisfactory, therefore, to know that

The Metropolitan Hospital Sunday Fund

has succeeded, under the presidency of Sir MARCUS SAMUEL, Bart., the late Lord Mayor of London, in raising the sum of £64,975 12*s.* 3*d.*, the largest amount ever collected since the inception of the Fund in 1872 Of this sum, £49,238 were collected in places of worship, showing an increase of £2907 over last year's figures. It will be remembered that their Majesties the KING and QUEEN with other members of the Royal Family attended at St. Paul's Cathedral on the Sunday preceding Hospital Sunday—namely, on June 7th—when, at the express desire of the KING, the offertory, which in spite of the unpropitious weather amounted to

£5389, was added to the amounts collected at other places of worship on Hospital Sunday. The Rev. Prebendary C. J. RIDGEWAY of Christ Church, Lancaster-gate, sent £1593; the Rev. Canon FLEMING of St. Michael's, Chester-square, £1406; and the Rev. Canon PENNEFATHER of the parish of St. Mary Abbots, Kensington, £1019. The number of contributing congregations was 62 in excess of those of last year. Mr. GEORGE HERRING, for the second time, added a quarter to the amount collected in places of worship and his generous gift amounted to £12,302. Mr. WILLIAM HERRING gave a special donation of £1000 to the collection at St. Paul's Cathedral. Among the large individual donations were one of £500 from Sir SAVILE CROSSLEY who sent a like sum to KING EDWARD'S Fund, one of £500 from "S. L., In Memoriam," and "Delta" sent a twenty-fifth donation of £200. The number of institutions which participated in the awards of the Fund was 209. The success which attended the Metropolitan Hospital Sunday Fund was not so fully shared by

King Edward's Hospital Fund for London,

for at a meeting of the General Council of the Fund held at Marlborough House on Dec. 15th the PRINCE OF WALES announced that the hopes which he had entertained at a similar meeting 12 months ago—namely, that another £10,000 a year would be forthcoming—had not been fulfilled. As, however, the financial year of the Fund has not yet ended it is to be hoped that some further substantial contributions may be announced at the final meeting. In order that the amount available for distribution might equal that of 1902—namely, £100,000—it was decided to draw upon the reserve funds. The amount received up to Dec. 10th was £71,033, to which the League of Mercy has added £10,000, this being £2000 more than it gave last year. The trustees of the London parochial charities have given £1000 for convalescent homes. A great part of the work of the KING'S Fund has been an endeavour to reopen beds which have been closed owing to want of means on the part of the hospitals, and since the Fund was started 443 beds have been made again available for patients. Ten beds have been reopened this year. A sum of £10,500 has been set apart for the purpose of assisting small special hospitals to amalgamate. A list of awards will be found on page 1831 of our present issue. Steady progress has been made by

The Metropolitan Hospital Saturday Fund,

the income to Dec. 12th being £16,628, as compared with £16,412 on the corresponding date of last year. It is interesting to note the progress that the Fund has made since the abolition of the street collection in 1897. In that year £20,138 were collected, including £3330 from street boxes. The authorities state that the Fund has now more than recovered the loss incurred by the abolition of the street collection and has distinctly increased in public favour. The main income of the Fund is derived from the penny-a-week collections in the workshops and places of business in London. This is steadily maintained notwithstanding the many other claims which are made upon the small resources of the workers. A special department has been created for the supply of surgical appliances upon payment by the patients of over 50 per cent. of the net cost. More than 3600 instruments are annually provided by this department under the supervision of a special committee assisted by competent surgeons and fitters. Towards the cost of these appliances the patients contribute over £2000. Special arrangements are also made for sending men, women, and children to convalescent homes when recommended for such benefit by a medical man. Some 1300 patients were so sent during 1902, many on the part-pay system, nearly £650 being paid by the patients or their friends towards the cost of their maintenance. Another special department of the Fund is the ambulance department, by means of which trained to render first aid in cases of accidents in the workshops or in the streets, but mostly in the workshops; and in cases where the employés of the firm subscribe £5 per annum to the Fund and include a man or woman holding a first aid certificate of the St. John Ambulance Association they are supplied on loan with completely fitted ambulance boxes. The awards for 1902 amounted to £20,902 as against £19,244 in 1901. The awards for 1903 will not be decided till Jan. 23rd, 1904.

PUBLIC ASPECTS OF SANITATION.

The Sewers of Bristol.

A considerable amount of argument has arisen from the fact that though the death-rate of Bristol compares favourably with other towns the sewers are stated not to be ventilated. This assertion is so absolutely opposed to all the well-established principles and theories that the facts seemed to call for explanation. Consequently our special sanitary commissioner instituted an inquiry on the spot. The result was a clear demonstration that it is altogether an error to state that the sewers of Bristol are not ventilated. There are certainly no grids opening on the street levels nor are there any ventilating shafts built purposely to let the air out of the sewers, but, apart from the fact that the soil-pipes of many houses have no intercepter traps and serve as sewer ventilators, there is a large amount of accidental ventilation. Twice a day the sewers are water-logged by the incoming tide and if they were airtight they would explode under this great pressure. But apart from rat holes and untrapped soil-pipes, there are great storm overflow openings which perform the function of ventilating shafts. Where such means of escape are not near at hand, then the sewer air can easily force its way through the water seal of such houses as are supplied with soil-pipe intercepter traps. The principal lesson to be derived from the experience acquired at Bristol does not show that there is no need to ventilate sewers. At best it indicates that in many instances where ventilation is purposely provided this is done in so imperfect a manner that mere accidental ventilation, such as exists at Bristol, is apt to be quite as effective.

The Housing Question at Aberdeen.

In regard to the housing controversy—which is always with us—a very interesting account was given of what has occurred on the outskirts of Aberdeen. So far back as 1808 the town council actually built nearly 200 cottages so as to house a colony of fishermen who had to abandon their homes in order to make room for the new jetty and port then being built. These cottages remained communa property till 1870, when the council reversed its policy and sought to induce the tenants to purchase their homes instead of merely renting them. From the sanitary point of view nothing is worse than very small property owners. Fishers'-square, as this district is called, is not drained; there are no closets and no water-supply in the cottages and outside there is no pavement. The insanitary conditions are such that it would be easy to prosecute the householders but this would not improve matters. The inhabitants are thrifty, steady, trustworthy fishermen but they literally have not got the money to pay for any of the alterations and improvements which are necessary to render their cottages healthy. Had the town retained possession of the property it could easily have made the necessary additions and as it is able to borrow money at a very low rate the rents charged need not have been largely increased. As it is matters are at a standstill and this because the city fathers of 1870 were not as wise and as far-seeing as their predecessors of 1808

The Sewers of Cheltenham.

Subsequently our attention was drawn to a very strange state of things still surviving at Cheltenham. Here some of the sewers are private property. They were made for profit and the corporation must not interfere with them, yet if they get out of order the owners say it is not their business to mend them. Many of these sewers were built by private speculators at the commencement of last century when Cheltenham emerged from the condition of a mere village and gradually became a fashionable place of residence. Of course they are now out of date and are worn out and do not harmonise with the general scheme of drainage which is applied where the town council exercises its full rights. These private sewers occasionally burst, inundate cellars, and are a source of constant complaint and nuisance. It is true that Section 40 of a local Act of 1852 empowers the sanitary authority to call upon the owners of the sewers to repair or to reconstruct them and if the owners refuse the authority may do the work. But the authority must recover the cost from the tenants who, in their turn, might take action against the owners. The whole situation was carefully explained and is so complicated that the only practical solution is for the municipality to buy out all the owners of private sewers. Attempts, indeed, have been made to introduce a Bill in Parliament to obtain the right to make such a purchase but various vested interests have succeeded in wrecking this project and Cheltenham remains in an anomalous position. As a health resort its reputation must suffer from this state of affairs and energetic measures should be taken to secure proper drainage.

Ankylostomiasis.

It was in the month of June that we first called attention to the very serious condition of the Westphalian coal mines. In some of these as many as 90 per cent. of the miners had been found to be infected by the ankylostoma duodenale. In the Ruhr coal-fields there were more than 25,000 miners affected. In Belgium also, in the Liège district, there were as many as 70 per cent. of cases among the miners in some of the coal-pits. Subsequently this subject was debated at length by the International Congress of Hygiene and still more recently by the delegates at the annual gathering of the Miners' Federation of Great Britain. Fortunately the disease so far has only been observed in some tin mines of Cornwall; it has not yet reached the coal-fields of England. It seems to have commenced with the piercing of the St. Gothard tunnel and then to have spread to Hungary. After that it reached Belgium and Germany and there have also been cases in France. The cases in Cornwall are said to have come from South Africa and, at all events, the mischief done on the continent is so serious that it behoves us to take every precaution to prevent similar trouble on this side of the Channel.

The Water-supply of Gibraltar.

The original and what must be described as an audacious scheme for placing Gibraltar beyond all risk of a water famine was fully described. Already in 1898 some portion of the rock above the town was shorn of all vegetation and the crevasses were filled in and cemented so as to constitute a smooth catchment ground. Then four great reservoirs were cut into the rock, where 5,000,000 gallons of water could be stored well away from bombs and shells and changes of temperature or the light of day. The nearest point of the reservoir is 50 feet away from the surface of the rock and 340 feet above the sea. The water was found unaltered when analysed after remaining 12 months in one of these reservoirs. It was thought that 5,000,000 gallons held in reserve would amply suffice; but the water is found so useful for industrial purposes, notably for the boilers of steam engines, and can so readily be sold that the necessity arose for another and much larger scheme. This consists of covering a sandy slope with corrugated iron so as to convert it into a gathering ground. But this slope is on the other side of the rock and just above Catalan Bay. To bring the water above the town of Gibraltar it was necessary to pierce a tunnel of 2025 feet through the rock. However, this is no loss, for the tunnel can be used as a reservoir and can be made to hold 17,000,000 gallons. Then, indeed, will Gibraltar be absolutely safe against drought, however extravagantly the inhabitants may use the water. These works were visited and minutely described.

The Water-supply of Granada.

Very different was the story told in regard to the water-supply of Granada. Here in 1885 the cholera caused such havoc that 313 deaths occurred in a single day from this disease. If cholera was proportionately as fatal among the 5 000,000 inhabitants of Greater London this would mean 20,000 deaths in one day. The water-supply of Granada was then contaminated throughout its course. After such a terrible warning it might be expected that the water would have been protected. Nothing whatever has been done. We published reproductions of photographs showing how filth reached the water-supply which is distributed and drunk unfiltered. All these years have elapsed and the water at Granada is to-day as susceptible to contamination as it was at the time of the great epidemic. The statistics show that in the absence of cholera there is a very high general death-rate with a specially high death-rate from intestinal disorders. The inhabitants complain of their poverty but travellers and pleasure seekers are afraid to go to Granada. The few who are bold enough to venture there generally visit the Alhambra and promptly hurry away, deeming themselves lucky if they only suffer from a passing attack of diarrhœa. It would pay to substitute iron pipes for the present open canalisation and porous pottery pipes which are accessible to contamination along their whole course.

The Sandgate Sanatoriums.

Our attention was directed to the little town of Sandgate. Here there are about 2000 inhabitants and some alarm was created by the presence of perhaps as many as 500 patients suffering from tuberculosis. Is it desirable, despite the comparatively slight infectivity of tuberculosis, that so many sick persons should be dumped down in the midst of a small community of healthy people? The larger number, but not all, of the tuberculous patients are lodged in homes organised on a purely commercial basis by a somewhat notorious individual named JOHN JAMES JONES. Here it is professed that outdoor treatment is given but the report which we published showed that there was no space for outdoor treatment, for the houses are in the street and not in the centre of a park or of gardens. The outdoor treatment consists of going into the public street and the inhabitants object to such proximity with patients. Also there was then no resident medical man in charge who was responsible for the treatment and diet of the patients, and such an enterprise ought not to be under the sole control of a person who is not technically qualified and who undertakes the whole affair merely as a money-making business.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Sir WILLIAM SELBY CHURCH, Bart., K.C.B., was for the fifth time elected President, the practically unanimous vote of the Fellows testifying to their approval of the manner in which he had fulfilled the onerous position of head of the College.

During the year the College considered the position which it held in regard to the General Medical Council, more especially in regard to the examinations. The result of the deliberations, however, in this latter respect has not yet been made public.

A report was received from the committee appointed to consider and to report on the practical safety and prophylactic value of antityphoid inoculations. The committee arrived at the following conclusions: "After careful scrutiny of the statistics from both official and private sources which have been made available we are of opinion that not only is a lessened susceptibility to the disease brought about as a result of the inoculations but that the case mortality is largely reduced. We are further of opinion that with due care the process of inoculation is devoid of direct danger, but that under special circumstances there may possibly be some temporary increase of susceptibility to infection immediately following inoculation, and it is therefore desirable that the preparation of the vaccine and the inoculations should be carried out under specially skilled supervision." The work of preparing a revised edition of the "Nomenclature of Diseases" has been vigorously pushed forwards during the year by the committee appointed for the purpose.

The adjudicators of the Weber-Parkes prize and medal selected the following subject for the next award in 1906, "The Degree of Infectivity of Pulmonary Tuberculosis and the Administrative Measures desirable for the Control and Treatment of the Disease."

A communication was received from a Member of the College offering a sum of money (£500) for the purpose of encouraging investigation into matters connected with tuberculosis, leprosy, plague, and malaria and suggesting that for this purpose a lectureship should be established to be styled "the Dr. Horace Dobell Research Lecture on the Ultimate Origin, the Evolution, and Life-history of Bacilli and other Pathogenic Micro-organisms." The generous offer was accepted by the College and a committee was appointed to carry out the trust.

The following awards were announced: The Gilbert Blane medals, awarded by the College and also by the Royal College of Surgeons of England, to CHRISTOPHER LOUIS WHITE BUNTON, Surgeon R.N., H.M.S. *Forte*, and JOHN FALCONER HALL, Staff Surgeon R.N., Naval Brigade, North China. The Weber-Parkes prize and first medal to Dr. HUGH WALSHAM and the second medal to Dr. WALTER JOBSON HORNE The Council recommended that the Moxon medal should be awarded to Dr. JOHN HUGHLINGS JACKSON, F.R.S., as having pre-eminently distinguished himself by observation and research in clinical medicine. The Council also recommended that the Baly medal should be awarded to Dr. JOHN NEWPORT LANGLEY, D.Sc., F.R.S., of Trinity College, Cambridge, as having especially distinguished himself in the science of physiology. Mr. ARTHUR RICHARDSON, late of Epsom College, was appointed Jenks scholar for the ensuing year.

The official lectures for the year, as we have already said, were delivered by Dr. H. TIMBRELL BULSTRODE, Dr. T. R. GLYNN, Dr. C. E. BEEVOR, Dr. A. S. F. GRÜNBAUM, and Dr. E. F. TREVELYAN. The Harveian orator for the year was Dr. W. H. ALLCHIN who selected as his subject the Study of Structure in Relation to Function.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The past year has, on the whole, been comparatively uneventful. At the elections to the Council in July there was but little contest. Mr. ALFRED WILLETT and Sir FREDERICK TREVES, two of the members of Council whose term had come to an end, did not seek re-election, but the third, Mr. H. T. BUTLIN, and Mr. G. H. MAKINS, Mr. C. T. DENT, and Mr. F. S. EVE were candidates, and of these Mr. BUTLIN, Mr. MAKINS, and Mr. DENT were elected, Mr. BUTLIN heading the poll. Since the date of election Mr. T. R. JESSOP has died and Mr PICKERING PICK has resigned, so that there will be two extra vacancies on the Council to be filled in July, 1904 Two former members of the Council, Mr. WILLIAM CADGE of Norwich and Mr. GEORGE LAWSON, have died. The term of office as President of Sir HENRY G. HOWSE came to an end in July and Mr. JOHN TWEEDY was elected President of the College, Mr. HENRY MORRIS and Sir ALFRED COOPER being appointed Vice-Presidents. An annual meeting of the Fellows was summoned for July 2nd, but only six Fellows were present and these included the President and the two Vice-Presidents. The abstention of the Fellows may be explained by the fact that there were no agenda for the meeting. In consequence of the continued inability to form a quorum at the meetings of Fellows the Council has decided to suspend during 1904 the rule which requires that one such meeting should be called yearly in July. At the annual meeting of the Fellows and Members in November the usual motion was carried claiming for the Members the right to representation on the Council. Another resolution requested the Council to receive a deputation of Members on the same subject. When these resolutions were subsequently discussed by the Council it decided that it was not expedient to reopen the question of the representation of Members on the Council. A motion requesting more information as to the proceedings of the Council was withdrawn when the PRESIDENT explained that the full minutes of the Council were suspended in the hall of the College, and the Council has since resolved to exhibit the minutes of the Council also in the Fellows and Members' common room and in the library. The last motion dealt with the dispute between the Council of the College and the General Medical Council as to the places for instruction in the elementary science subjects, but the motion was not carried.

The John Tomes prize was awarded to Mr. KENNETH WELDON GOADBY. The Jacksonian prize was awarded to Mr T. CRISP ENGLISH, of St. George's Hospital, for his dissertation on Fracture of the Skull, its consequences immediate and remote, including Pathology and Treatment. An honorarium was also awarded to Mr. LOUIS B. RAWLING for the excellence of his essay on the same subject. The subject for the Jacksonian prize in 1904 is the Diagnosis and Treatment of such Affections of the Stomach as are amenable to Direct Surgical Interference.

The Bradshaw lecture was delivered by Mr. HENRY MORRIS, his subject being Cancer and its Origin. The Hunterian oration was delivered by Sir HENRY G. HOWSE. At the Hunterian dinner Lord ROBERTS was admitted to the honorary Fellowship. One member of 20 years' standing was elected Fellow, Sir FRANCIS HENRY LOVELL, C.M.G., Dean of the London School of Tropical Medicine and late Surgeon General of Trinidad.

A replica of the bust of Sir WILLIAM MAC CORMAC, executed by Mr. ALFRED DRURY, A R A., for St. Thomas's Hospital, was presented to the College by the subscribers. The College has purchased a portrait by GEORGE RICHMOND, R A, of the late Mr. HENRY HANCOCK, President of the College in 1872 Professor RETZIUS of Stockholm has presented to the library a valuable set of scientific works. A purchase of some interest is a doctor's signboard dated 1623, which exhibits in different panels the chief operations performed.

The excess of income over expenditure for the financial year was £2004. The College lent some of its valuable pathological specimens to the University of London for the purpose of its examinations, but it has suggested to the University the desirability of conducting its pathological examination at the College in order to prevent that damage to the specimens which is very likely to result from frequent removal to and fro The Council was requested to give its views to the Worshipful Company of Spectacle Makers on the suggested inclusion of sight testing in the examination for the diploma of the company. In its carefully considered reply the Council pointed out the danger of anyone without an efficient medical and surgical training being deemed competent to prescribe a medical or surgical remedy or appliance. The London County Council having asked the College to suggest the names of well-qualified pathologists to make post-mortem examinations and to give evidence in special inquest cases the Council declined to make any nomination and pointed out the inadequacy of the fee of two guineas for the services required from medical men so highly accomplished as skilled pathologists.

THE BENEVOLENT AGENCIES OF THE PROFESSION.

Epsom College, late Royal Medical Benevolent College.

An important event in the history of this institution was the meeting of governors held on Nov. 26th, under the presidency of the Earl of ROSEBERY, when it was decided to change its name to "Epsom College" and to add the following sub-title to all documents issued from the office of the charitable side of the work in London: "Established in 1855 as a Public School with a Royal Medical Foundation." Prominence is thus given to the fact that the college founded by Mr. PROPERT nearly 50 years ago is a public school. The college has extensive playing fields, an excellent swimming bath which has recently been reconstructed at a cost of about £1000, a detached sanatorium, a well-equipped laboratory, a lecture theatre, a lower school capable of accommodating 100 junior boys, fives courts, a biological laboratory, a modern laundry, a carpenter's shop, and a system of drainage which has been carefully arranged under expert advice in recent years at great expense. The fee charged for sons of those not members of the profession, 75 guineas, is a moderate one; sons of medical men obtain a reduction of 10 guineas; there are entrance scholarships of £30 a year and there are "council exhibitions" for the sons of less fortunate members of the profession, which reduce the fee to 35 guineas. Foundation scholarships to the number of 50 are provided for the necessitous sons of medical men, the holders of which are educated, clothed, and maintained free of cost. Owing to the generosity of the hospital authorities there are numerous scholarships at the hospital schools in London ranging in value from 120 guineas to £150, and through the liberality of living and deceased friends of the college there are also a number of scholarships and exhibitions for science and classics from £30 to £60 in value for boys leaving to go to the universities. Provision is also made for 50 pensionerships. At the twenty-ninth festival dinner of the college, which was held at the Hotel Cecil on June 10th, the PRINCE OF WALES, who presided, said that he could hardly imagine that there were any institutions more deserving of public support than those the object of which was to help members of the medical profession and their families who through misfortune or otherwise were brought to reduced circumstances. The foundation scholarships and the pensionerships, however, are far from obtaining a satisfactory measure of support and every medical practitioner ought to subscribe at least 5*s.* a year towards the benevolent side of the institution. No one has worked with greater energy on behalf of the college than Dr. CONSTANTINE HOLMAN, the treasurer, whose services were fittingly acknowledged at a meeting of the council on August 5th when Sir JOSEPH FAYRER presented to Dr HOLMAN, on behalf of the members, an illuminated address and a portrait which now hangs in the council chamber of the college, 37, Soho-square, London, W.

The British Medical Benevolent Fund.

During the year assistance has been given to 160 deserving applicants, to whom sums amounting to £1661 have been voted, payable generally in small monthly instalments. The cases have been, as always, of a most distressing nature, but owing to the falling off in subscriptions many have had to be passed over or postponed and few could be adequately helped. A climax was reached at the October meeting of the committee when with 16 applications on the list there was no available balance and an account at the bank was overdrawn to the amount of £52. A special appeal was therefore decided on and as a result £270 have since been received. To all those who kindly came forward to help the committee asks us to tender most sincere and hearty thanks. In the annuity department the interest on invested capital has yielded an income of £2503, of which £2302 have been distributed amongst 116 annuitants. Legacies amounting to £2860 have been received. Following the rule this amount has been invested and the interest will be devoted to the payment of annuities. The committee earnestly appeals to the profession for assistance and would point out that the working expenses of the charity are only just over 5 per cent. and that the accounts are audited every year by a well-known firm of chartered accountants. Subscriptions and donations may be sent to the treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

Society for the Relief of Widows and Orphans of Medical Men.

During the year 12 new members have been elected, three having died, and three having resigned. The members number 298. Two widows and six orphans have applied for relief, three widows have died, and one orphan has become ineligible. At the end of the year 53 widows and 15 orphans were in receipt of half-yearly grants. A sum of £3922 10*s.* has been distributed during the year. The expenses have been £246.

THE LANCET *Relief Fund,*

for the purpose of affording immediate pecuniary assistance to medical men or their widows and orphans in cases of distress and emergency by grants of money on loan free of interest or by gifts, has assisted some 37 persons during the past year, involving an expenditure of £432 16*s.* 6*d.* As the accounts are not made up till the end of the year there is a probability that these figures may fall short of the actual totals.

CONTRIBUTIONS FROM THE LANCET LABORATORY.

Several questions of medical interest have occupied attention in THE LANCET Laboratory during the year. In the first number of THE LANCET, published on Jan. 3rd, on p. 71 appeared an article on the Chemistry of the Oyster and Some Remarks with Regard to its Dietetic Value. The results of the inquiry threw some fresh light upon the nutritive value of the oyster and brought forward points of dietetic significance. Amongst other things the amount of liver sugar was found to be much less than that recorded by previous observers. Copper appeared to be a constant constituent of the mineral matter but in minute amount. Experiments on the solubility of the oyster showed that the crushed oyster yields more than one-half of its constituents to cold water, while only a fourth of the solid contents of the uncrushed oyster is dissolved. The cold water extract gave on heating an albuminous coagulum and on concentrating the watery extract a brown liquid was obtained which was indistinguishable as regards taste and smell from well-prepared beef-tea and developed osmazone to a remarkable degree. It is to be hoped that it will soon be possible to declare that the oyster beds of this country are free from any risk of pollution with sewage.

In THE LANCET of Jan. 31st, p. 327, an article from THE LANCET Laboratory was published on the Analysis of the Water from the Holy Well of Zem Zem. The analysis referred to a sample sent to us by Sir HORACE H. PINCHING, K.C.M.G., Director-General of the Sanitary Department of the Ministry of the Interior at Cairo. Evidence was obtained in favour of intense pollution still taking place and in this regard the results were worse than those which were obtained in THE LANCET Laboratory in 1892 but almost identical with those obtained with a sample submitted to us in 1883. Microscopical examination showed the presence of fibres derived from personal clothing, a not very surprising result seeing that the pilgrim retires grateful when he feels that the cloth round his loins is wet.

In THE LANCET of Feb. 14th, p. 465, appeared the results of an *investigation* by our Laboratory Commissioners into a process of cleaning by vacuum. The process is of great sanitary importance as it removes the dust from the carpets, walls, and upholstery of the house very effectually and without any need for disturbing the furniture, whilst causing no nuisance of any kind. We gave an account of the results of an actual trial of the vacuum machine in a ten-roomed house; an analysis was published showing the composition of the dust obtained and the results of a microscopical examination were also detailed. Since our report appeared the process has found a very wide application, as, for example, in removing the spilt grain in a granary or brewery and extracting the dust from the upholstery of railway carriages; in a number *of other ways it has also proved satisfactory.* In the case of theatres the application of the machine has removed close upon 500 pounds of dust lodged in the carpets, the curtains, and the cushioned seats of the auditorium.

The publication of the report of THE LANCET Special Analytical Commission on Brandy in THE LANCET of Nov 29th, 1902, p 1503 drew very considerable attention to the general question of the practice of substitution in the spirit trade. We dealt with this question in regard particularly to the blending of malt spirit with grain spirit in the production of whisky in our issue of Feb 21st, p. 542 This article made a considerable impression upon the public and the trade, especially as we were able to state that chemical analysis afforded a means of differentiating an all-malt spirit from a blended whisky. We urged that some control should be brought to bear upon this enormous practice of substitution. We suggested that it should be insisted that on the labels of the bottles of all spirits there shall be printed a clear statement of the nature of the contents, whether the spirit be an all-malt whisky or partly malt and partly grain spirit or an all-grape brandy or a partly grape and partly grain spirit, and so forth. There can be no objection to the sale of blends so long as they are sold as such, but it is obviously fraudulent to offer a mixture when a pure unmixed spirit is expected or asked for. We pointed out that there is no reason why the Excise authorities should not undertake the control of this labelling and accurate description of spirits, for the Inland Revenue authorities must know exactly the pedigree and the history of all the spirit produced in the United Kingdom.

We dealt again with the increasing practice of substitution in an article in THE LANCET of Oct. 17th, p. 1104, which gave rise to some correspondence in our columns. Our remarks had their origin in a civil action in which the plaintiff sought to recover damages from the defendant for fraudulent misrepresentation in regard to the sale *of boots* We had the *opportunity of inspecting* a specimen of the kind of boot which was supplied in answer to the description of "solid." On ripping up the outer sole strips of cardboard were found inserted between the outer and inner sole. In the same article we gave the results of the examination of a piece of silk taken from the sleeve of a blouse which had caused an acute irritation of the skin. An analysis disclosed that *the* material was loaded with no less than 40 per cent. of mineral matter consisting, as further examination showed, of the oxides of aluminium and tin with distinct traces of arsenic. We appeal again for a system of control over such pernicious practices and for the suppression of the scandal of substitution.

In consequence of certain allegations having been made against pharmacists who were accused of substituting cheap for the more expensive drugs included in a prescription we made a *short practical inquiry into the matter.* We secured samples of medicine made up in response to a test prescription and submitted them to careful analysis The results were decidedly in favour of the integrity of the dispenser and in fact the figures afforded by analysis were in remarkable agreement with those required by the prescription, although the prescription was so made up as easily to admit of the substitution of one drug for another as, for example, *sulphate of quinine for the hydrochloride,* potassium bromide for sodium or ammonium bromide.

In THE LANCET of May 30th, p. 1537, we called attention to the dirty state of the waters of the fountains in Trafalgar-square. We published an analysis of a sample taken by ourselves and the results were very unsatisfactory. Our remarks elicited the fact that for the sake of economy the water pumped from the fountains is used over and over again and we understand that the source of supply is an artesian well which is also used for supplying water to Buckingham *Palace, Marlborough House, the Houses of Parliament,* and the Government offices. We have reason to believe that the authorities concerned have been more vigilant lately in their endeavours to keep the fountains and the pools in Trafalgar-square cleaner.

In THE LANCET of June 20th, p. 1758, were published some interesting facts based upon laboratory experiments regarding the purifying effect upon the air of the heavy rainfall which has been so persistent this year. It was shown that the chief impurity washed out of the air is *ammonia in the form of sulphate, the origin of which, of* course, is the combustion of coal. There were also present common salt, soot, and suspended matters.

In THE LANCET of July 4th, p. 41, we pointed out that the floods occasioned by heavy rain were having a bad effect *upon the drinking water supplied to London by those* companies which draw water for the purpose from the Thames or the Lee A chemical analysis of the New River supply was made in THE LANCET Laboratory and the results obtained were compared with an analysis of the same water made at a normal period. The results showed, as we anticipated, a slight increase in the amount of chlorides, of free ammonia, and of albuminoid ammonia, and a diminution in the degree of hardness and in the amount of nitrate, while instead of being nearly colourless or slightly blue the water exhibited a distinctly yellowish-brown colour.

On the occasion of the inauguration of the new water-supply at Margate on August 6th, one of our *Laboratory* Commissioners made an inquiry into the scheme and his results were published in THE LANCET of August 15th, p 487. Margate now possesses a pure and abundant water-supply taken from the chalk downs lying between the borough and the city of Canterbury.

In summarising the events of the year 1902 we observed that we quite failed to understand why the recommendations of the Departmental Committee on Preservatives and Colouring Matters in Food, which were published in November, 1901, had not been considered and embodied in the statutes. Another year has elapsed and absolutely nothing has been done towards making these recommendations part and parcel of the provisions of an Act. The practice of preserving food, as was pointed out in THE LANCET of Oct. 24th, p. 1180, goes on practically uncontrolled, at any rate, by statute.

The number of *specimens of foods, drugs, and other* articles examined in THE LANCET Laboratory and reported upon in our analytical columns was 113 and the number of analyses thus involved was 505. In connexion with special inquiries the number of single analytical determinations made was 86, bringing the total to a little short of 600

INTERNATIONAL CONGRESSES.

The Fourteenth International Congress of Medicine.

As Professor BROUARDEL truly remarked, the International Medical Congresses find their very existence endangered by their success. The first Congress met in Paris in 1867 and the fact that i was attended by some 300 medical men was then considered very wonderful. The Fourteenth International Congress of Medicine met at Madrid during the last week of April this year and there were some 7000 members present. At best the accommodation at Madrid is limited. The town is not situated on one of the great highroads of international traffic. Then such hotels as exist were already fuller than usual in consequence of the Easter holiday visitors and because the country being in the throes of a general election a large number of politicians went to the capital for instructions. When, in addition to this crowd, 7000 members of the Medical Congress arrived a situation was created that could only be met by the exercise of the genius of organisation sustained by well-trained business faculties. Now these are qualities in which the Spanish people as a race are singularly deficient. Nor is the medical profession as a profession calculated to develop such special capacities. The result was a remarkable state of chaos accompanied in not a few cases by shameful extortion. A false impression was allowed to prevail that the organisers of the Congress were also arranging for the reception and the housing of the members. The latter therefore sent as instructed £2 to the "Service des Logements" and expected to find that rooms had been retained for them. But on arriving at Madrid they found themselves at the mercy of extortionate agents and not in the hands of a committee formed by the organisers of the Congress. They were first of all called upon to pay for ten days' board and lodging in advance, being assured that such coupons given in exchange as were not used would be reimbursed. Then when they got to the lodgings they found them bad or inferior considering the price paid. In answer to complaints the landlords explained that they had to pay heavy commissions to intermediaries and if the visitors had dealt directly they could have had the same accommodation for a much smaller sum. Thereupon many members did deal directly with the landlords and went to the Congress offices to get their coupons reimbursed. This produced a panic similar to a run upon a bank and the office for lodgings had not enough ready cash in hand to reimburse the coupons, so the cashier had to close his office. As an excuse for this a rumour was spread that forged coupons to the extent of 7000 pesetas had been cashed. Now the lodging-house keepers who had accepted coupons in payment were also seized with panic and came clamouring down to the closed door of the cashier's office. Finding they could not get paid some of them refused to accept any further coupons from their lodgers. The latter, who had paid at exorbitant rates in hard cash and in advance for ten days' board and lodging, were in a very awkward position, particularly if they had not enough money in hand to pay twice over for their board. Fortunately this state of affairs did not last long. The cashier ultimately resumed payments, the coupons were honoured, and after a while the pandemonium that had prevailed at the Congress offices subsided.

There has been much disorder at other congresses but the climax was reached at Madrid. As for the scientific work done, that also was somewhat chaotic—there were so many sections and it was so difficult to know when at any one section any one paper would be read. Many members simply wandered about from section to section with the vague hope of hearing something that might interest them. Excursions to Toledo, to the Escurial, and to many institutions, hospitals, asylums, and the like did not fail to prove more attractive than the work of the sections. The latter were therefore remarkably empty in spite of the very large number of members of the Congress actually in Madrid who could, and perhaps in different circumstances would, have attended them. However, if these absentees failed to contribute to the discussions there was a formidable array of papers presented and read. These will constitute ponderous volumes and among the many things recorded there are some of undoubted value. Time will show which of the new suggestions made will permanently survive and meanwhile it will be recognised that this great Congress, with all its confusion and the trouble that arose, was a mighty and a fruitful work. It demonstrated that there was a lack of organising capacity but the very inconveniences thus created afforded to our Spanish hosts innumerable opportunities of displaying the courtesy, the friendliness, and the charm of manner and of bearing for which the nation stands pre-eminent in Europe. From the KING and the QUEEN DOWAGER down to the man at the street corner everyone was ready to help in every way and to befriend and to honour the guests of Spain. This greatly facilitated the smoothing over of the material difficulties that had occurred. Also, the great ceremonies, above all the opening ceremony at the Grand Opera House, were magnificently organised. For pomp and stateliness they were unequalled. The reception in the palace —and it is one of the finest palaces in Europe—and the subsequent garden party in the palace grounds were so impressive and brilliant that they will not be forgotten and all who were present will remember gratefully the hospitality which the representatives of medical science of the world received at the hands of the Royal House of Spain. But others, according to their more modest means, were equally hospitable and whatever the town or institution the members of the Congress visited they were always cordially received and made welcome in every way.

The Eleventh International Congress of Hygiene and Demography.

As a contrast to the International Congress of Medicine the Eleventh International Congress of Hygiene and Demography was one of the most perfectly organised gatherings of the sort ever held. It is true that the task was much easier and also it must be recognised that the science of hygiene embraces within its ranks a far greater number of efficient organisers and business men than does the science of medicine. For instance, hygiene includes sanitary engineering, certain phases of architecture, and various administrative functions, sanitary police, and the like. Hence on the committees of such congresses there are men habituated to the work of administering, of organising, and of providing for the transport of people from place to place and all the business transactions attached thereto. If medical men had to manage hospitals it might help them to acquire such business capacities; but hospitals are generally managed by laymen, so that few medical men have experience how provision should be made for the reception and entertainment of a sudden inrush of several thousand strangers. The case is very different when we have to deal with experienced chiefs of Government departments, such as M. E. BECO, the Secretary-General of the Ministry of Agriculture and General Director of the Public Health Services of Belgium. This gentleman was the president of the International Congress of Hygiene under the honorary presidency of H.R.H. Prince ALBERT. Around him were gathered engineers who had superintended works where hundreds of people were employed and functionaries hardened in the routine of bureaucratic work. Many weeks before the Congress met the members had a list of the hotels with their tariffs and were able to apply directly to the landlords without any intermediary being able to make a commission out of the transaction. The reports which were to be discussed in the seven sections of hygiene and in the division of demography were printed as quickly as they were received. Many of them were distributed weeks before the Congress met. Where there was delay it was the fault of the reporters who had not done their work in time and not the fault of the organisers of the Congress. A daily paper issued in the morning kept the members of the Congress well informed as to what was going on in each section and the reports being read and studied beforehand each interested person knew exactly what part he might be able to take in the discussions. Consequently the sections were crowded, the debates were well sustained throughout, and a really serious week's work was accomplished. There was not a hitch anywhere. Certainly this Congress was much easier to manage than the Medical Congress, first because there were only some 2000 members present and, secondly, because Brussels is situated on one of the most frequented international highways and is far better accustomed to receive travellers of all nationalities. Nevertheless, a congress of 2000 members is quite large enough to degenerate into a mere mob if not carefully organised and in respect to organisation the Belgians certainly distinguished themselves. The general secretary, Dr. PUTZEYS, and the secretary, Dr. VOITURON, were ubiquitous and they had behind them a very efficient staff of clerks. There were the usual banquets, the reception at Court, and the excursions, with the accompaniment of still more banquets. Then there was a gala theatrical performance and, in a word, pleasure was not neglected, though, as the lengthy reports which we published fully demonstrate, much work was done. Nor was this work confined to study and discussion; it has already, in one important respect at least, ripened into action. The proposal made at the Congress by different persons and for different objects, that some sort of permanent international bureau should be established has been adopted. The Congress of Hygiene met at the commencement of September. The International Sanitary Conference met at Paris on Oct. 10th. Here an international agreement was drawn up by the official representatives of the different Powers. Never before has an official conference of this sort been so well attended. The representatives of 25 nationalities were present and 20 out of them were authorised to sign the convention drawn up. This convention contained a clause establishing a permanent international sanitary office which will be located in Paris and where all nationalities will be represented. Doubtless, at first, its task will consist chiefly of facilitating the international exchange of information, but this, in course of time, will tend to encourage international legislation on sanitary matters where such agreements between nations are found to be of mutual benefit. It will be seen, therefore, that the admirably organised International Congress of Hygiene held at Brussels last September has not been long in producing practical results.

THE ORGANISATION OF THE PROFESSION.

This year we carried our investigations into Wales where we found a determined effort had been made at Swansea to establish a medical union. Here the members of friendly societies paid the same sum for medical attendance whether married or single and the medical officer was expected to attend the families of the members. This payment was on an average 5s. 6d. per year—far too little for a family—but 2s. 2d more than single men generally pay. Dr. T. D. GRIFFITHS, however, related that he once had a club at Swansea and all the members paid 5s. a year. He contracted with a local druggist for medicine at an average charge of 6d. per bottle and pills at 2d. per box. As a consequence at the end of the year he found that his drug bill exceeded by £11 the sum which he had received from his club Thus Dr. GRIFFITHS had given his services for nothing and had also spent £11 out of his own pocket, and yet the workmen whom he had attended would have been most indignant if they were told that they were in receipt of charity. Another club of 500 members offered payment which he calculated would be equal to 1½d. per consultation Therefore, and so as to clear ½d per consultation the medicine given should not cost more than 1d. No wonder that at 6d. a bottle such transactions resulted in an actual loss. It is fortunate indeed that the profession has at last risen up against such a state of affairs and we were pleased to record that unanimity prevailed at Swansea and that substantial advantages had been obtained. Much still remains to be done but a step forward has been taken and further progress may be anticipated. The threat of the friendly societies to create a medical institute of their own has not been realised and the members of the Medical Practitioners' Association of Swansea and district have obtained better terms and, what is still more beneficial, have put an end to the former disastrous competition which divided the profession against itself.

Unfortunately, the situation is not nearly so good at Cardiff. In this, the most important town in South Wales, there seems to be a total absence of public spirit among the members of the profession. The subscribers to the clubs pay generally 1d. per week and family clubs are not so prevalent as at Swansea, but there are many abuses and a considerable amount of canvassing. On one occasion a woman canvasser was employed to extol the virtues of the medical officer who attended on all who took out a life insurance policy from a certain company. This lady canvasser presented herself to the patients of various medical men—patients who were in the habit of paying the ordinary fees and could well afford to do so. Nevertheless, she suggested that they should insure their lives and then only a penny per week would be charged for medical attendance.

At Aberdare there is a colliery surgeons' society and in many places it has succeeded in carrying out what is called the "poundage" system. This is certainly the fairest of all systems. The miners pay 3d. in the £1 for medical attendance out of the wages which they receive. Thus an increase of wages means an increase of pay for medical attendance and where the pay is poor it is because the patients themselves are really poor. The difficulty here, if any, is rather among the medical men themselves and not so much in regard to their dealings with patients. The question at issue is whether the contract work, which is much better paid under the poundage system, should be divided between many practitioners or concentrated in the hands of one or two of the highest standing who employ qualified assistants. It is argued that several practitioners each receiving but a small sum cannot be equipped with operating tables, surgical instruments, and other necessaries on the same lavish scale as where the medical services are centralised. We pointed out hat there is here an interesting scientific, practical, and economical problem. Shall the work and responsibility be concentrated? Shall two leading practitioners employ on the wages system, order, and direct six qualified assistants? Or else, shall eight independent practitioners, each with his own individual practice and his small income, carry out the work? The rival principles of collectivism and individualism have thus manifested themselves even in regard to the methods of attending colliers and this is one of the several ways in which the economic évolution affects medical practice as it affects all other economic conditions of modern civilisation.

At Pontypridd some ten years ago a Medico-Ethical Society was founded. Its influence has been exercised mainly over colliery surgeons. The object and policy of this organisation have been ethical rather than economic. This is doubtless due to the fact that the society was founded before the present movement in favour of medical unions had been started. As a consequence, at a pit in the smaller of the two Rhondda valleys the excellent poundage system of payment has been abolished by the miners and they have employed a medical man at a fixed salary. A lay committee is now exploiting its medical servant. The Medico-Ethical Society should have fought against this but not being organised as a medical union it was unable to do so.

At Cheltenham, on the other hand, there is quite a young society, founded in 1901, and it at once was engaged in an economic struggle Here the Oddfellows and members of other benefit societies only paid 3s. a year for medical attendance and the members of the medical profession decided that they would not accept less than 4s. a year and 10s. for the whole family. At first these terms were granted. Later, however, a dispute arose in regard to the political clubs. These also have sick benefits but as they only seek to organise voters they do not enrol women members. This, from the medical point of view, is preferable to the practice prevailing among the Oddfellows and friendly societies generally which, on the contrary, have often sought to establish female lodges. Now one of the medical officers, having expressed this opinion perhaps too freely, was accused of persuading the members of a friendly society to join a political club. As the members of the friendly society were for the most part Radicals and their medical officer was also medical officer of the Conservative club, politics were mixed up with the question at issue. This ultimately resulted in the founding of a medical institute and the importation of a medical man to reside at the institute and to act as the attendant on all the members of the federation of various societies which had come together for this purpose. It is not certain, however, whether this venture will pay its way.

The case of Dr. LACHLAN GRANT, whose right to practise in the district of the Ballachulish slate quarries has now been restored to him by the directors of the company working the mines, attracted the attention during the year of all those interested in the maintenance of the rights of the medical profession. In the proper section the legal position of the case is alluded to, and the fact is mentioned that Dr. GRANT'S interdiction was declared by more than one court to be legal. There can be no doubt, however, that the directors have acted with justice as well as prudence in yielding to the quarriers' wishes. The details of the case are familiar to all our readers.

HONOURS TO MEDICAL MEN.

It is a pleasant task in making our chronicle of the year's events to record the names of those members of the profession who have received public recognition of their services. For the last two or three years we have been able to close our list of honours with the names of members of our profession who have won the coveted distinction of the Victoria Cross but this year the country has fortunately had no large military operations on hand and consequently there has been little opportunity for medical men to distinguish themselves on the field. The following plucky deed, however, will rank with those for which the cross with the motto "For Valour" is awarded.

The Albert Medal.

At the levée held in March His Majesty the KING presented Captain HERBERT CUMMING FRENCH, R.A.M.C., with the decoration of the Albert Medal, second class. On Nov. 17th, 1902, H.M. Transport *Wakool* was steaming through the Straits of Malacca at a rate of about 12 knots per hour when a native fireman jumped overboard. Captain FRENCH, who was a passenger, immediately dived into the sea from the promenade deck, a height of about 36 feet, and swam to the place where the fireman had been last seen. When, however, he reached the spot the man had sunk and Captain FRENCH, becoming exhausted by the weight of his clothing, had to make for a life-buoy. Both men were eventually rescued by the life-boat. A strong current runs at the place and Captain FRENCH incurred great risk of being caught by the ship's screw; in addition to this danger sharks are frequent in the Straits of Malacca.

Birthday Honours.

His Majesty the KING having decided that the celebration of his birthday should take place in this country during the summer and at foreign stations on the actual date of his birth—namely, Nov. 9th—there have been issued in consequence two lists of Birthday Honours. The first list included the names of Mr. ALFRED DOWNING FRIPP, C.B., C.V.O., Dr. STEPHEN MACKENZIE, Dr. EDWIN COOPER PERRY, and Dr. PATRICK HERON WATSON, each of whom received the honour of knighthood. Sir ALFRED FRIPP did excellent work in South Africa during the war and since his return home has supplemented that work first as a member of Mr. BRODRICK'S committee for the reorganisation of the Army Medical Services and subsequently as a member of the Advisory Board in connexion with the medical department of the army. Sir STEPHEN MACKENZIE is well known as a physician of very wide attainments. Sir EDWIN PERRY, like Sir ALFRED FRIPP, is a member of the Advisory Board for the Army Medical Services, and Sir P. HERON WATSON, honorary surgeon to HIS MAJESTY in Scotland, is the representative of the Royal College of Surgeons of Edinburgh upon the General Medical Council and is an ex-President of the College which he represents. In the same list occur the names of Dr. PATRICK MANSON, C.M.G., who was promoted to be a Knight Commander of the Order of St. Michael and St. George, Surgeon-General COLVIN SMITH, C.B., I.M.S., and Surgeon-General JOHN BY COLE READE, C.B., A.M.S., who were made Knight Commanders of the Bath, and Surgeon-General GEORGE JOSEPH HAMILTON EVATT, A.M.S., and Surgeon-General ADAM SCOTT REID, I.M.S., who received Companionships of the Bath. Sir PATRICK MANSON, the medical adviser to the Colonial Office, received his promotion from Companion to Knight Commander of the Order of St. Michael and St. George for special services in connexion with tropical diseases, and Sir COLVIN SMITH and Sir JOHN READE were elevated to the higher grade of their Order for military services.

The November list of honours included the names of Dr. A. R. MANBY, M.V.O., who was made a Knight; Captain T. H. M. CLARKE, R.A.M.C., D.S.O., who received a Companionship of the Order of St. Michael and St. George for services in Crete; and Dr. ROBERT BELL, acting director of the Department of Geological Survey, Canada, who was appointed a Companion of the Imperial Service Order. Sir A. R. MANBY is surgeon-apothecary to the KING and to the PRINCE of WALES.

Honours in connexion with the King's Visit to Ireland.

In connexion with the Royal visit to Ireland Dr. ARTHUR VERNON MACAN and Mr. LAMBERT HEPENSTAL ORMSBY received knighthoods. Sir ARTHUR MACAN is President of the Royal College of Physicians of Ireland and Sir LAMBERT ORMSBY is President of the Royal College of Surgeons in Ireland. Dr. CHARLES B. BALL received the honour of knighthood at the hands of the Lord Lieutenant of Ireland. Sir CHARLES BALL represents the Royal College of Surgeons in Ireland on the General Medical Council.

The Durbar Honours.

Among the recipients of the Durbar honours were Dr. GEORGE WATT, C.I.E., who was made a Knight; Surgeon-General WILLIAM ROE HOOPER, who was appointed a Knight Commander of the Star of India; and Surgeon-General BENJAMIN FRANKLIN, who was appointed a Knight Commander of the Order of the Indian Empire. Sir GEORGE WATT is officer in charge of the Economic and Art Section of the Indian Museum, Calcutta; Sir WILLIAM HOOPER is President of the Medical Board at the India Office; and Sir BENJAMIN FRANKLIN is Director-General of the Indian Medical Service. Lieutenant-Colonel GERALD BOMFORD, I.M.S., Principal of the Medical College, Calcutta, and Major ALFRED WILLIAM ALCOCK, F.R.S., I.M.S., superintendent of the Indian Museum, were appointed Companions of the Order of the Indian Empire. Lieutenant-Colonel ROBERT WILLIAM STEELE LYONS, I.M.S., superintendent of Dharwar Lunatic Asylum, and Major DAVID SEMPLE, R.A.M.C., director of the Pasteur Institute, Kasauli, received the Kaisar-I-Hind medal.

Kano Sokoto Expedition

In recognition of his services in connexion with the Kano-Sokoto expedition Mr. WILLIAM HENRY LANGLEY, deputy principal medical officer, Protectorate of Northern Nigeria, was appointed a Companion of the Order of St. Michael and St. George.

Foreign Orders.

President LOUBET, on the occasion of his visit to this country in July, pinned on the breast of Mr. EDMUND OWEN, F.R.C.S., the ribbon of the Chevalier of the Legion of Honour. Dr. PERCY ATHELSTAN NIGHTINGALE has had conferred upon him the Insignia of the Fourth Class of the Royal Siamese Order of the White Elephant in recognition of valuable services rendered to the Government of Siam when acting as Siamese delegate to the International Medical Conference at Brussels; and Dr. F. M. SANDWITH has received the Insignia of the Third Class of the Order of the Osmanieh, which has been conferred upon him by his Highness the KHEDIVE of EGYPT in recognition of valuable services rendered.

Honours for Ambulance Work

Dr. JOHN JOHNSTON and Dr. J. HILTON THOMPSON received the special medal for meritorious services during the South African war.

OBITUARY.

The close of another year gives us cause once more to tell the tale of those members of our profession who have passed from this life. Some have reached the utmost limit of human existence and some have fallen almost at the opening of their career. But all, young or old, have done their best in the fight with disease and death and their memories remain for an example to their fellows. In accordance with our usual custom we have made a classification of those deceased as follows.

Royal Navy Medical Service.

On Feb. 10th there died in his eightieth year NARCISSUS COLLINS HATHERLY, M.D. Aberd., M.R.C.S. Eng., staff surgeon R.N. (retired). Dr. HATHERLY was for ten years (1852–62) senior assistant surgeon at the Royal Naval Hospital, Plymouth. For many years he resided in South Molton and was identified with nearly all the works of philanthropy of that town. GILBERT KIRKER, M.D., M.Ch. R.U.I., M.R.C.S. Eng., Fleet Surgeon R.N., died at Haslar on Nov. 24th. His death was due to septicæmia following a wound of his finger received during an operation. He graduated as M.D. of the Royal University of Ireland in 1878 and in the following year was admitted a Member of the Royal College of Surgeons of England. After serving with the Turks in the Russo-Turkish war he returned to England and entered the Royal Navy Medical Service in 1879. He served through the Egyptian war of 1882 and afterwards was assistant professor at Haslar until in 1891 he was appointed staff surgeon. He was next placed in charge of the Royal Naval Hospital at Esquimalt. He was well known throughout the British navy and also in foreign navies for his invention of an ambulance sleigh for transporting wounded on board ship.

Army Medical Service and Indian Medical Service

EDWARD EUSTACE, M.D. Durh., L.R.C.P. Edin., L.R.C.S. Irel., Surgeon-Lieutenant-Colonel A.M.D., died at Cheltenham on Feb. 16th, aged 62 years. He qualified in 1863 and shortly afterwards entered the Army Medical Department, being in charge of the Women and Children's Hospital at Netley in 1873–74. He then served in India and in 1834 was superintendent of the Military Hospital at Devonport. He retired from the service soon after with the honorary rank of surgeon-lieutenant-colonel and settled down to practice in Weston-super-Mare. JOHN BRAKE, M.R.C.S. Eng., L.S.A., Surgeon-General, Indian Medical Service (retired), died on Feb. 8th at Southsea. He was educated at the City of London School and St. Thomas's Hospital. In 1854 he entered after competition the medical service of the Honourable East India Company. He served for 31 years in India commencing with the Mutiny and afterwards doing work in Simla, the Central Provinces, and Bombay. In September, 1886, he retired with the rank of surgeon-general and lived for some time at Brighton and Winchester. WILLIAM HENRY NEILSON, M.B., C.M. Aberd., Lieutenant-Colonel, I.M.S., died at Indore, Central India, on March 23rd. He became an assistant surgeon in the Indian Medical Service in 1882 and in 1894 was promoted to be surgeon-major with the honorary rank of lieutenant-colonel. JOHN IVOR MURRAY, M.D., F.R.C.S., M.R.C.P. Edin., who died in London on July 24th, saw much foreign service both in war and peace. Born in 1824 he was educated in France and at the University of Edinburgh and gained in 1844 a commission as assistant surgeon in the army. There was, however, no vacancy and he proceeded to China, where he was in charge of the Canton Hospital during the anti-foreign outbreak of 1846. On the commencement of the Crimean war he went to Sebastopol, serving at Balaclava. He next served as colonial surgeon at Hong-Kong but in 1872 returned to England and settled at Scarborough. JOHN HENRY SYLVESTER, Deputy Surgeon-General I.M.S., who died in London on Nov. 29th in the seventy-fourth year of his age, went to India in 1854 under the India Office. He served for a while in Persia, then in India through the mutiny, and, finally, at the Jamjetsee Jeejeebhoy Hospital as professor of physiology. He left India in 1875.

Hospital Physicians and Surgeons.

ALEXANDER THOMSON, M.D., L.F.P.S. Glasg., who died on Jan. 18th, aged 70 years, was educated at the University of Glasgow and in 1861 settled in Dumfries. Ten years later he was appointed visiting physician to the Dumfries and Galloway Infirmary, resigning this post in 1874 to fill a vacancy on the surgical staff, a post which he held to within two years of his death. He was the first country surgeon in Scotland to operate for ovarian tumour, successfully removing one in 1865. Besides holding his hospital post he was for 33 years medical officer of health of the burgh of Dumfries. JAMES PRIESTLEY, M.D. R.U.I., who died on March 31st at the age of 38 years, studied medicine in Belfast, graduated M.D. in 1897, having previously obtained the Diploma of Public Health of the Royal Colleges of Physicians of London and Surgeons of England in 1893. He did much public health work for the then vestry of Paddington and was for three years senior medical officer of the North Eastern Hospital, Tottenham. He died from septicæmia contracted in the discharge of his duties as a private practitioner at Lee-on-the-Solent, where he settled in 1888. SOLOMON CHARLES SMITH, M.D. Durh., M.R.C.P. Lond., M.R.C.S. Eng., who died at Walton-on-Thames on April 5th, was educated at Birmingham, Guy's Hospital, and Paris, qualifying as M.R.C.S. Eng. in 1863. In 1868 he was elected one of the surgeons to the Halifax Infirmary, but removed to London in 1890. It was mainly owing to his efforts that the Royal Halifax Infirmary was built and opened by the Prince and Princess of Wales in 1896. WILLIAM CADGE, F.R.C.S. Eng., who died in Norwich on June 25th, aged 81 years, needs no further notice here to keep his name in remembrance. His generous benefactions in the cause of charity and his admirable professional work have been already set forth at length in the obituary notice published in THE LANCET of July 4th. JOHN WOODMAN, M.D. St. And., F.R.C.S. Eng., L.S.A., died on June 28th at Exeter. He was in his sixty-seventh year and received his medical education at Guy's Hospital, whence he qualified as M.R.C.S. in 1860. In 1870 he was made a Fellow of the

Royal College of Surgeons of England and graduated as M.D. in the University of St. Andrews in 1882 He settled at Exeter and was on the staff of the Exeter Dispensary as well as being medical officer of health of the city. ROBERT HALL WOODHOUSE, M.R.C.S. Eng., L.S.A., L.D.S., who died in July at the age of 52 years, received his medical education at the Middlesex Hospital. After obtaining the diploma of M.R.C.S. he studied dentistry at the Dental Hospital of London and later was elected surgeon to that institution. He did much in a quiet way to raise the status of the dental profession. FRANCIS HARRISON WALMSLEY, M.R.C.S. Eng., L.S.A., who died on July 16th in his seventy-fifth year, was educated at the Pine street School of Medicine, Manchester, and qualified in 1849. In 1855 he was appointed an honorary surgeon to the Salford Royal Hospital. In 1864 he was elected a member of the Salford town council and did admirable sanitary work, being specially interested in the question of river pollution. SAMUEL FARRANT, M.R.C.S. Eng., L.S.A., who died at Pitminster on July 18th in his sixty-sixth year, was a pupil of the late Mr. C. H. CORNISH, a medical practitioner of Taunton. Mr. FARRANT was for many years an honorary surgeon to the Taunton and Somerset Hospital. He took great interest in municipal matters and was at one time mayor of Taunton. JOSEPH GRIFFITHS SWAYNE, M.D. Lond., M.R.C.S. Eng., L.S.A., who died at Clifton on August 1st in his eighty-fifth year, received his medical education at the Bristol Medical School and at Guy's Hospital. He qualified in 1841 and settled down to practise in Clifton. For 20 years he was physician accoucheur to the Bristol General Hospital. He was also for some time professor of midwifery at University College, Bristol, and a teacher at the Bristol Medical School for 50 years. He took great interest in Church matters and was a member of the building committee of All Saints' Church, Clifton. WILLIAM ALPHONSO HENDERSON, L.R.C.P. & S. Edin., who died in Florence during August, qualified in 1869 and proceeded to China. He was for some time medical officer to the Imperial Maritime Customs at Chefoo and Ningpo, and also medical officer to the Church of England and Presbyterian Hospitals. The names of the three practitioners who come next on the list of those departed—namely, GEORGE WILLIAM BALFOUR of Edinburgh, WILLIAM SMOULT PLAYFAIR of London, and JOHN TATHAM—are so well known in the medical world and the careers of these physicians have been so fully set forth in THE LANCET of August 22nd that we need not here recapitulate the details HENRY GRAY CROLY, F.R.C.S., M.R.C.P. Irel., who died on August 28th at Rathfarnham, was for more than 25 years surgeon to the Royal City of Dublin Hospital. JOHN EDWARD BOYTON, M.R.C.S. Eng., L.A.H. Dub., who died on Sept. 4th at Watlington, had attained the great age of 87 years. He qualified in 1838 and commenced practice in Watlington where he was for many years on the staff of the Watlington Cottage Hospital. WILLIAM EDMUND IMAGE, F.R.C.S. Eng., who died in October at Mildenhall, was born in 1807 and was thus 96 years of age at the time of his death. He was educated at Guy's and St. Thomas's medical schools and settled in Bury St. Edmunds. In 1844, being consulting surgeon to the West Suffolk Hospital, Bury St. Edmunds, he was elected one of the first honorary Fellows of the Royal College of Surgeons of England About 20 years later he retired from practice. WILLIAM JOHNSON WALSHAM, M.B., C.M. Aberd., F.R.C.S. Eng., who died at his residence in London on Oct. 5th, received his medical education at St. Bartholomew's Hospital and in due course of time was elected surgeon to that institution. An able surgeon and a kindly and skilful teacher, his death is a heavy blow to the ancient foundation of which he was so devoted a member. THOMAS JAMES PICKBURN, M.D., C.M. Aberd., M.R.C.S. Eng., L.S.A., who died in Sydney in the month of October in his fifty-seventh year, received his medical education at St. Bartholomew's Hospital. He commenced practice some 35 years ago in New South Wales and had practised in Sydney for 25 years. For some years he was one of the physicians to the St. Vincent's and the Sydney Hospitals. ROBERT JOHN GARDEN, M.D. Aberd., who died on Oct. 23rd, received his medical education at the University of Aberdeen and also studied at Berlin, Würzburg, and Vienna. In 1874 he started practice in Aberdeen and soon became a member of the staff of the Royal Infirmary. Three years before his death he retired from his office which was then that of senior surgeon. Sir GEORGE FREDERICK DUFFEY, M.D. Dub., F.R.C.P. Irel., who died in Dublin on Oct. 13th, was educated at the University of Dublin and entered the Army Medical Service in 1867. After serving for nine years he resigned his commission and settled down to practise in Dublin. In 1876 he was appointed physician to Mercer's Hospital, resigning this post in 1882 to become physician to the Royal City of Dublin Hospital. In 1896 he was appointed President of the Royal College of Physicians of Ireland and in 1897 received the honour of knighthood. GEORGE LAWSON, F.R.C.S. Eng., who died on Oct. 12th in his seventy-third year, was consulting surgeon to the Middlesex Hospital and to the Royal London Ophthalmic Hospital, Moorfields, and surgeon oculist to Queen Victoria. His career has been so fully set forth in our issue of Oct. 24th that there is no need to recapitulate the details here. PHILIP BROOKES MASON, M.R.C.S. Eng., L.S.A., who died on Nov. 6th, was educated in Glasgow, in his father's surgery at Burton-on-Trent, and at University College, London. He qualified in 1864 and after holding various appointments in London he was recalled to Burton by the sudden death of his father whose practice he took over. From 1870 to the time of his death he was surgeon to the Burton Infirmary. Sir ROBERT MARTIN CRAVEN, Kt., F.R.C.S. Eng. and Edin., J.P., who died on Nov. 15th, was, like his grandfather and father before him, a prominent practitioner in Hull. He was surgeon to the Hull General Infirmary, was justice of the peace for the East Riding, and was sheriff of Hull. WILLIAM NEWMAN, M.D. Lond., F.R.C.S. Eng., who died on Dec. 3rd, aged 70 years, received his medical training at St. Bartholomew's Hospital. In 1863 he settled in Stamford and was soon appointed surgeon to the Stamford and Rutland Infirmary, an office which he held for 30 years, being then made consulting surgeon. Besides his purely professional work he was very well read, was a good draughtsman, and a great authority upon education.

State and Municipal Officials.

WILLIAM HENRY CROSSE, M.D. Durh., M.R.C.S. Eng. L.F.P.S. Glasg., L.S.A., who died in London on Feb. 24th, will long be remembered for the excellent work which he did in the service of the empire as principal medical officer to the Royal Niger Company. His death was due to disease contracted in the discharge of his duty and his valuable researches upon blackwater fever, many of which were published in our columns, are notable additions to our knowledge of a scourge which so terribly afflicts many parts of the world. WILLIAM HENRY CORFIELD, M.D. Oxon., F.R.C.P. Lond., who died at Marstrand, Sweden, on August 26th, was born in 1843 at Shrewsbury. He went to Cheltenham Grammar School and afterwards obtained a Demyship at Magdalen College, Oxford. He next obtained a Sheppard Medical Fellowship at Pembroke College and won the Radcliffe Travelling Fellowship in 1867. He studied at Paris and Lyons and at various other places on the continent, and in 1869 was appointed the first professor of hygiene and public health at University College, London. His valuable work in the department of public health is well known and for more than 28 years he was medical officer of health of the parish of St. George's, Hanover-square. Sir Charles Nicholson, Bart., M.D., D.C.L., LL D., who died at the beginning of November within a few days of his ninety-fifth birthday, was born in Yorkshire. He studied medicine at the University of Edinburgh, where he graduated M.D. in 1833. In the following year he settled in Sydney and was one of the founders of Sydney University. In 1843 he gave up practice and entered Parliament as a member of the first Legislative Council of the colony. On three occasions he was elected Speaker and was knighted in 1854, receiving the further honour of a baronetcy in 1859. About 1864 he left Australia and settled in London. Oxford gave him the honorary degree of D.C.L. and Cambridge and Edinburgh that of LL.D.

Other Practitioners.

Among the many other medical men who have ended their life work we may mention the following:—Paul Quick Karkeek, M.R.C.S. Eng., L.S.A., who died on Dec. 27th, 1902, at Torquay in his sixtieth year was a well-known medical man in the west of England. He received his medical education at St. Bartholomew's Hospital, qualifying in 1865, and was shortly afterwards appointed assistant surgeon to the Seamen's Hospital, Greenwich. He next studied medicine on the continent and finally settled down at Torquay, where in 1878 he was elected medical officer of health, a post which he held until his death. It was mainly owing to his efforts that the water-supply of Torquay is so efficient. Richard Chandler Alexander Prior, M.D. Oxon, F.R.C.P. Lond., F.L S., who died on Dec. 5th, 1902, having nearly reached the completion of his ninety-fourth year, was educated at the Charterhouse School, Wadham College, Oxford, and St. George's Hospital. Subsequently to graduating in medicine at Oxford he practised in Bath but his health failing he abandoned active work and devoted himself to the study of botany. John Webb Watkins, M.D. Edin., M.R.C S Eng., was a well-known practitioner in the north of England. He was educated at University College, London, and at the University of Edinburgh and he was the first human subject other than himself upon whom Simpson tried the anæsthetic properties of chloroform. He died on Jan. 30th. John Orton, M.R C.S Eng, L.S A, who died during the month of February, practised in north Warwickshire and took an active interest in political questions. William Saul, M.D. St. And., M R C S. Eng., L.S.A., who died suddenly on March 11th, practised for many years at Boscombe, near Bournemouth. He was greatly interested in parochial affairs and for the last five years of his life served the office of churchwarden to the Church of St. John, Bournemouth. Thomas John Maclagan, M.D. Edin., M.R.C.P. Lond., who died on March 20th, was for many years a well-known practitioner in Chelsea He is best known to the medical profession by his work on rheumatic fever and as being the introducer, or rather the renewer, of the use of salicin in the treatment of that disease. Edward Wilmshurst Tait, who died on March 31st, was for over 40 years a well-known practitioner in the north of London. Edward Monro Spooner, M.D. St. And., M.R.C.S Eng., L.S.A., who died at Blandford on April 7th, was born in 1840 and was educated at Epsom College and the London Hospital. He qualified in 1864 and succeeded to his father's practice at Blandford. Besides holding other posts he was surgeon to the Blandford Cottage Hospital. Henry James Moxon, L.D.S. R C.S. Eng. and Irel., died on June 3rd after an operation for appendicitis. He was the first dentist to be appointed to a Poor-law institution—namely, the North Surrey District Schools, Anerley. Alfred Haviland, M R.C.S. Eng, who died at Frimley Green on May 30th, received his medical education at University College Hospital, London. He practised in partnership with his father for a short time in Bridgwater, but having contracted septicæmia during an operation he had to resign active work and thenceforward took up the study by which he contributed such valuable results to medical knowledge—namely, researches into medical geography. Before having to give up professional work he was on the staff of the Bridgwater Infirmary. John Birkbeck Nevins, M.D. Lond., M.R.C.S. Eng., who died in June, aged 84 years, was for a long period one of the best-known practitioners of the city of Liverpool. John Alexander Cooksey, M R C.P. Edin., M R C S Eng., who died on July 19th, practised first at Chipping Camden and afterwards at Malvern. He was a sufferer from that danger to which all the members of our profession are exposed —namely, of having charges of a grave nature brought against him, but in one case the prosecuting counsel withdrew the case and in the other the jury acquitted him without hearing all the witnesses for the defence. William Burns Macdonald, M.A., M B., C.M Edin., who died on August 2nd from the remote effects of a bicycle accident, practised at first in Spain and afterwards at Lossiemouth and Dunbar. He was widely read, a good linguist, and had travelled much. *Frederic Norton* Manning, M.D St. And., M.R.C S. Eng., who died in Australia on June 18th, originally served in the Royal Navy, but his life's work lay in the great reforms which he was the means of introducing in the treatment of the insane in Australia. Of other practitioners we may mention Walter Sumpter, M D. St. And., L S A, who died on Sept. 9th and was for many years a prominent practitioner in Norfolk; David Illtyd Jones, L.R C P., L R C.S.Edin., L.M, L.F.P.S. Glasg., who died on Sept 25th, a well-known member of the profession in South Wales; William Berry Kellock, M.D St And., F.R.C.S Eng., who died at the age of 82 years and who practised for many years in Stoke Newington; William Dingley, M.R C S Eng, L S.A, who died on Nov. 17th, and who commenced his medical studies at the age of 16 years in the year 1844 by serving as an apprentice to a surgeon in Sherborne. He practised after qualifying for over 50 years in the north of London; and Samuel Woodcock, M.D. Brux, L R.C.P. and L.R.C.S. Edin, who died at the age of 63 years on Dec. 12th, and who was for many years a prominent figure in Manchester medical and political circles. He was at one time president of the Lancashire and Cheshire Branch of the British Medical Association. In 1892 he was made a magistrate for the city of Manchester.

Distinguished Foreign Medical Men.

Amongst eminent foreign medical men whose deaths have been noted in our pages we may again refer to the brilliant Italian surgeon Enrico Bottini, professor of surgery in the University of Pavia. He died from cerebral hæmorrhage on March 11th. He received his medical education at the University of Turin, whence he graduated in 1860. Five years later he was appointed surgeon-in-chief to the Ospedale Maggiore at Novara and in 1877 was elected to the chair of surgery in the University of Pavia. His name is perhaps most familiar to medical men from his work in connexion with the treatment of disease by means of the galvano-cautery. Italian medicine suffered another grievous loss this year in the death from an accident of Francesco Colzi who died in Florence on April 4th. Colzi was educated at the University of Pisa and at Florence, where in 1879 he was appointed to the post of assistant surgeon at the Hospital of Santa Maria Novella. In 1892 he was elected extraordinary professor of surgery in the University of Modena but returned to Florence in the same year and finally succeeded his old chief Corradi as professor of clinical surgery. On March 25th he was at a pigeon-shooting match when his gun exploded and inflicted a grievous wound of his right axilla and humerus. Immediate death was averted by his own skill and pluck and hopes were entertained of recovery as collateral circulation apparently became established. Later, however, the arm had to be removed and tetanus bacilli were discovered in the fluids which oozed from the wound before operation. Despite injections of antitetanic serum he died on April 4th fortified by the last rites of the Church. Edmond Isidore Etienne Nocard, who died in his fifty-fourth year during the month of September while holding the post of director of the Veterinary School at Alfort, did valuable work which is known all over the world on the subjects of epidemic diseases amongst animals, some of which, as tuberculosis, are also common to man. He was a favourite pupil of Pasteur and 17 years previously to his death was elected a member of the Academy of Medicine of Paris. Professor Proust, who died on Nov. 26th from a paralytic seizure, was inspector-general of the French sanitary service and rendered his country invaluable aid as regards public health and preventive medicine.

So with the close of another year we end the list of those members of our profession who have passed away. May those of us who remain leave as good a record behind us when our time comes to go also. Their labours here are over and may they rest in peace.

Annotations.

"Ne quid nimis."

THE CHEMISTRY OF CHRISTMAS PUDDING.

Mr. Edwy G. Clayton, F.I.C., F.C.S., writes:—More than once, in medical journals and elsewhere, the suggestion has been made that chemical analyses showing the composition and food value of the national dish, world famous as Christmas pudding, would be of interest; and although at first sight the subject may seem trivial it is not so in reality. In a few days millions of people, children and adults, will be consuming this triumph of the culinary craft, which for several days at all events must form no small part of the diet of the empire in the most diverse circumstances and in every latitude. Palace, cottage, poor house, ship, and barrack, each has its Noël fare; and few, indeed, are the Christmas feasts at which plum-pudding does not fill an important place. Two puddings, made at different times but from the same recipe used in one household for more than 20 years, have been submitted to analysis and the results are stated below:—

	A.	B.	Mean of the two analyses.
Water	33·35	37·82	35·58
Nitrogenous substances	3·75	4·75	4·25
Fat	5·03	5·38	5·20
Sugar (glucose)	26·00	21·78	23·89
Dextrin	14·41	11·45	12·93
Starch	13·03	9·25	11·14
Cellulose	3·29	7·34	5·31
Acetic acid	—	0·23	—
Tartaric acid	—	0·88	—
Soluble ash	0·89	0·96	0·92
Insoluble ash	0·25	0·16	0·20
	100·00	100·00	—
Alkalinity of ash, as potash	0·08	—	—
Phosphoric acid (combined):—			
Total	0·25	0·20	0·225
Soluble	—	0·15	—
Insoluble	—	0·05	—

Summary.

Water and volatile matter (loss at 100° C.)		33·35	38·05	35·70
Solid matter		66·65	61·95	64·30
Organic constituents		65·51	60·60	3·0
Inorganic components		1·14	1·12	1·1
In the original substance.	Nitrogenous matters	3·75	4·75	4·25
	Non-nitrogenous organic components	56·73	50·93	53·83
	Fat	5·03	5·38	5·20
In the dried substance.	Nitrogen	0·89	1·21	1·05
	Nitrogenous substances	5·63	7·66	6·64
	Non-nitrogenous constituents	85·12	82·21	83·66
	Fat	7·55	8·65	8·10
Nutrient ratio*		1 17⅓	1·11½	1·14½
Nutrient value †		68·8	69·6	64·2

---

* Ratio of nitrogenous components to carbohydrates, excluding cellulose but including fat calculated into its starch equivalent.

† The sum of the percentages of nitrogenous substances, sugar, dextrin, starch, and fat, calculated into its starch equivalent.

The proteids were practically entirely soluble in water. Alcohol was present in each case but in traces only. The cellulose was higher in B than in A, probably because the seeds had not been so carefully removed from the raisins. It appears that, although most agreeable as an article of food, plum-pudding is not quite so concentrated a form of diet as has been supposed and conjectures that it yields as much sustenance as beefsteak are certainly not supported by its chemical composition. The amount of nitrogenous matter is only moderate and it must be remembered that in calculating the nutrient ratio and value all the nitrogen has been assumed to be albuminoid. Probably the true albuminoids, and consequently the food value, are slightly lower than would appear from the results. Also, the percentage of water is rather large and the quantities of the remaining components are proportionately lessened. It is not easy to compare precisely other articles of diet with plum-pudding as regards nutrient value but probably dried figs and dates approximate to it somewhat closely.

BIRTHS IN WORKHOUSES.

The zeal of boards of guardians does not always take satisfactory directions but an agitation now in progress which has for its object the removal from pauper children of the disability which publication of the fact of their having been born in a workhouse entails seems deserving of support. Some months ago the Coventry guardians suggested to the Registrar-General that births in their workhouse should be recorded as taking place at "6, London-road," but it was objected that such a proceeding would introduce difficulties in the compilation of statistics as to births in workhouses. The idea was not, however, allowed to drop and as other boards, for instance, those of Hampstead and Leicester, made similar requests further consideration has been given to the matter. On Nov. 20th the Registrar-General received a deputation from the Coventry board and expressed sympathy with the arguments laid before him. Still more recently, on Dec. 2nd, a more thoroughly representative deputation, consisting of a vice-president and several members of the council of the Poor-law Unions' Association, including Mr. Crooks, M.P., interviewed the Registrar General who said that he joined in the desire of the boards to remove the stigma of workhouse birth in the same way as had been done in the case of births in prisons. It would be necessary to obtain the leave of the Local Government Board and as there was no legal difficulty in the way he would endeavour to obtain such leave if he found on further consideration that the matter could be carried out. He added that the subject had been mooted at an opportune moment as he was now engaged in revising the regulations issued to the registrars. Objection has b taken to the proposed change on the ground that it would tend to increase the number of women who go to the workhouse for their confinements. This is possibly the case but even so it does not militate against the scheme to any serious extent. There can be no doubt that the present mode of registration may materially prejudice the interests of workhouse children in later life. A "birth certificate" is in constant demand as proof of age and if it calls attention to the fact that the holder was born in a workhouse may raise obstacles in the way of obtaining employment or may even constitute among the thoughtless a social drawback, involving much injustice. It is idle to expect to eradicate without years of education the vulgar snobbishness which cannot recognise that "the man's the gowd" but it may be possible to avoid stimulating its display and the suggested change in the mode of registering births will help to that end.

CONFLICTING MEDICAL EVIDENCE.

THE *South African Medical Record* for November contained an outspoken and not altogether uncalled-for article upon the unsatisfactory conditions under which medical practitioners are called upon to give evidence in courts of law, conditions which are characterised as in the highest degree humiliating and even demoralising to the medical profession. The *South African Medical Record* refers to an unusually large number of actions for damages arising out of alleged negligence recently instituted in the Supreme Court of Cape Colony, but the subject is one which needs no special occasion to render it of importance. Actions such as those referred to, actions relating to life assurance, actions in which physical or mental capacity is in dispute, and charges of murder and of other crimes, are familiar to us all in which judges and juries have before them witnesses of high standing in the medical profession. In such cases it is not uncommon to find the witnesses upon the one side giving, with more or less confidence evidence directly opposed to that which is sworn to on the other. It must be observed that the conflict of testimony thus produced is not confined to the medical evidence but is observable in that of eye-witnesses [illegible] professed eye-witnesses of the facts in dispute who, so far as their circumstances are concerned, might be expected to be no less free from prejudice or from liability to error than medical men. The medical witness is, for the most part, an expert giving evidence of opinion which his training enables him to do, and if two men may differ upon the causes and details of an accident which both of them had seen two other men may at least as excusably differ with regard to the effect and duration of the injuries which the accident is alleged to have caused. The solicitor on the one side or the other naturally avails himself of such opinions as he may find to coincide with the interests of his client. The undesirable feature to which the *South African Medical Record* draws particular attention arises, however, not from the conflicts which to a large extent appear to be unavoidable, but from the fact that the task of deciding between two contradictory opinions is intrusted to a jury of laymen under the direction of a judge who has had no more medical training than those whom he has to guide to a verdict. The remedy suggested by the *South African Medical Record* would seem to lie in the appointing of medical assessors to advise the judge and mention is made in this connexion of the recent selection of a pathologist by the London County Council and to its desire that London coroners should employ him for the performance of post-mortem examinations in cases of doubt or difficulty. This, however, is hardly to be regarded as an instance of what has been or might be done in the direction indicated. The pathologist who makes a necropsy for the purpose of an inquest is merely a witness; he does not advise the coroner who is very often himself a medical man, and at inquests the opportunity for contradictory medical testimony seldom arises. An instance in England of the medical assessor might rather be found in the medical referees appointed under the Workmen's Compensation Acts where the damages awarded are measured by the period of disablement. An example of aid afforded to judges of the High Court in an easily determined class of case where technical knowledge is required is afforded by the Trinity Masters who sit as assessors in the Admiralty Division. In some foreign countries there is provision for medical assessors or for official medical witnesses and the practical working of the systems in vogue can therefore be studied. It must be remembered, however, that there are reasons to be urged against, as well as in favour of, employing a medical man or medical men to decide where their professional brethren disagree. The witnesses who differ are frequently men of the highest qualifications and of the strictest integrity, who hold honestly divergent opinions and the task of distinguishing between them would often be both difficult and invidious. The jury system is by no means a faultless one but to speak generally the 12 citizens in the box enjoy the confidence of the suitors and although judges sometimes express their disapproval of the verdicts given few judges would care to have cast upon them the onus of coming to a conclusion of fact in all cases without the jury's aid. The question is one, however, of admitted importance and interest in the settlement of which the me[illegible] and the legal professions will perhaps some day be able usefully to coöperate.

THE NEEDS OF THE MODERN HEALTH RESORT.

UNDER the above title Dr. Leonard Williams delivered an interesting address on Dec. 15th to the members of the East Sussex Medico-Chirurgical Society. Dr. Williams laid it down as a canon that a health resort, besides possessing mineral or sea water, should also possess a definite climate, whether bracing, relaxing, or intermediate. He also, we are glad to see, mentioned that climate from a medical point of view did not merely mean meteorological conditions but effects upon human beings. There is no doubt that the words "bracing" and "relaxing" have very different meanings for different people. It is Miss Braddon, we think, who says in one of her novels that the first thing that the serpent told Eve was that the Garden of Eden was very relaxing and many people if they are ill, or bored, or worried, or have eaten too much, at once say that the place in which they are is relaxing. Some, again, consider a climate like that of the eastern coast of Yorkshire in the spring bracing, while others find that a combination of bright sun and an east wind that cuts like a razor renders them miserable. Such people find a South Devon place a paradise, in which, however, members of the former class would sigh for fresh air. Dr. Williams further said that the modern health resort cannot rely upon climatic conditions alone. Rational amusements should be provided, sanitation, not only of the town as a whole but of all the private houses, should be rigorously enforced, and the bathing establishments, whether sea or mineral water, should afford every facility for obtaining modern treatment. With these remarks we are quite in accord and Dr. Williams might have added that any health resort to be worthy of the name should prohibit street shouting, German bands, and piano organs from making life unbearable. Dr. Williams concluded his address with some wise remarks to practitioners in health resorts. They should, he said, speak with no uncertain voice upon the regimen to be followed by visitors, and especially upon the diet. This, we consider, is excellent advice. No one could eat the same style of food at

Strathpeffer as at Bournemouth but no definite rules have been laid down upon the subject. Altogether the address should prove of use to those who heard it if they only take its advice to heart.

THE REGIUS PROFESSORSHIP OF MEDICINE AT OXFORD.

Sir John Burdon Sanderson, who has been Regius Professor of Medicine in the University of Oxford since the retirement of Sir Henry Acland in 1895, has intimated his intention of resigning the post on account of his advancing years. Sir John Burdon Sanderson had always intended to resign on reaching the age of 75 years and within a few weeks he will have attained the age in question. The retiring Regius Professor, before his election to the post which he is now resigning, was well known as a physiologist and as an authority on public health. In his early days he was one of the medical inspectors of the Local Government Board. He was Professor of Physiology at University College, London, from 1874 to 1882, and from 1882 to 1895 he was Waynflete Professor of Physiology in the University of Oxford. In 1883 he served on the Royal Commission on Hospitals and in 1900 on that appointed to inquire into the question of tuberculosis. Since his tenure of the Regius Professorship the Oxford school of medicine has greatly increased in importance. The holder of the professorship has now anything but a sinecure and whoever be elected to the post will have no easy task before him. To follow in the steps of two such able men as Acland and Burdon Sanderson calls for talents of no mean order while the increasing demands and influence of the Oxford medical school require not merely one with a grasp of modern medicine but also one who can take a broad and statesman-like view of the principles and influence of the medical sciences. While wishing Sir John Burdon Sanderson many years' enjoyment of a well-earned rest we may also hope that a successor may be found worthy to follow those who have preceded him in the honourable office of Regius Professor of Medicine in the University of Oxford.

HÆMOGLOBINURIC FEVER.

WE have received a pamphlet entitled "Hæmoglobinuric Fever, its Distribution and Etiology," by Mr. J. Wallace Collett, medical officer, Southern Nigeria. During recent years much light has been thrown upon the etiology of malaria and other tropical diseases but comparatively little is known concerning the causation of hæmoglobinuric or blackwater fever In this brochure Mr. Collett reminds his readers that at the present time two theories are propounded as to the etiology of this disease, one being that there is a relationship between blackwater fever and malaria, and the other, initiated by Veretas and Tomaselli and revived by Koch, that blackwater fever is nothing more nor less than poisoning by quinine. Mr. Collett gives his reasons for believing that neither of these theories satisfies the demands of science "sufficiently to be placed upon the category of probable facts or even plausible speculations." He considers, however, that there are several occurrences, both clinical and within the pale of bacteriological research, which would appear to encourage the idea that blackwater fever, if not a disease *sui generis*, is at least intimately connected with a class of diseases due to the infection of the system by a poison probably of a protozoal nature Mr. Collett then proceeds to make some remarks on the probable nature of the toxin in this disease. He draws attention to the action of hæmolysins and naturally suggests that with a view of discovering the cause of hæmoglobinuric fever it becomes necessary to look for a lysin which can produce the symptoms of the disease and which is not found in other pathological conditions. This is the proper course to pursue when searching for a pathogenic organism as a causal factor in any particular malady. Mr. Collett then refers to the bacillus megatherium which was first discovered in a fermenting infusion of cooked cabbage leaves and afterwards in samples of papain and infusions of hay, grass, and other vegetable matters. This bacillus has been proved to possess distinct hæmolytic powers. In alkaline broth, grown at a temperature of 99° F., this property is strongly developed and it has now been shown to be due mainly to an extrabacillary elaboration termed distinctively megatherio-lysin. Mr. Collett very rightly points out that the occurrence of the bacillus megatherium in decaying vegetable matter is a fact full of significance for West Africa where vegetation is so rankly luxurious. This organism has generally been considered as non-pathogenic but it has now been proved to be capable of elaborating products which, in susceptible animals, possess the power of bringing about such profound blood changes as *hæmoglobinuria*. *His suggestion, therefore, that there may* be a causal relationship between this bacillus and hæmoglobinuric fever is a plausible one but further investigation is, of course, necessary before any definite assertions can be made.

THE FIRST INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

THE First International Congress of School Hygiene will be held at Nuremberg from April 4th to 9th, 1904, and communications have already been announced from many well known authorities on the education and sanitary up-bringing of children. Professor Cohn (Breslau) will discuss, What has Ophthalmology done for School Hygiene and what has it still to do? Professor Axel Johannesen (Christiania) will describe the State of School Hygiene in Norway; Dr. Le Gendre (Paris), President of the "League of Physicians and Families," will discourse on the Hygiene and the Personal Diseases of Teachers; Dr. Sickinger, Ph D., chief inspector of the board schools of Mannheim, will take as his subject the Organisation of Elementary Schools based upon the Natural Capabilities of the Children; Professor Liebermann (Budapest) will define the Duties and Training of Medical Officers of Schools; Professor Hueppe (Prague) will read a paper on the Prophylaxis of Infectious Diseases in Schools; and Professor Eulenburg (Berlin) has chosen a rather gruesome theme, the Suicides of Scholars. Communications from all interested should be addressed to Herr Max Versen, editor in chief of the *Fränkischer Kurier*, Nuremberg.

A HISTORICO-MEDICAL EXHIBITION.

Mr. Henry S. Wellcome informs us that in commemoration of the fact that a quarter of a century has elapsed since the firm of which he is the head was founded he has decided to hold in London an exhibition in connexion with medicine, chemistry, pharmacy, and the allied sciences. "The exhibition," he says, "will be strictly professional and scientific in character. It will be my aim to bring together a collection of historical objects illustrating the development of the art and science of healing throughout the ages." Mr. Wellcome recognises that the success of the undertaking will largely depend upon the coöperation of those who are interested in these subjects. He is therefore issuing a circular which indicates the range of the intended exhibition. It is proposed to collect and to display all sorts of rare and curious objects relating to medicine, chemistry, pharmacy, and the allied sciences. The exhibits will be classified under seven sections :—

Section I.—Paintings, drawings, engravings, photographs, medallions, and sculptures of historical interest of—(A) distinguished physicians, surgeons, alchemists, apothecaries, chemists, nurses, &c.; (B) ancient

British and foreign medical, chemical, and pharmaceutical in- [illegible] records of experiments, diplomas, [illegible] other personal relics of medical, [illegible] rest; apparatus associated with [illegible], chemistry, and pharmacy. In Section 4, under the style "Curiosities of Medicine,' will be shown: (A) Materia medica of all ages (specimens of ancient medicines in all forms); (B) formulæ of all ages; (C) ancient and modern medicine chests—civil, military, and naval; (D) votive offerings for health, ancient and modern amulets, medals, seals, emblems, charms, and talismans; medical relics of savage and primitive peoples; (E) corporate insignia and diplomas of British and foreign colleges of physicians; (F) rare and curious memorials of medical practice; (G) memorials of medication by animal substances; and (H) memorials of the influence of astrology on medicine. Section 5 will be for curiosities of surgery—(A) relics of ancient and mediæval surgery, dentistry, and veterinary surgery; (B) ancient and mediæval hospital equipment; (C) curious anatomical models; (D) historical surgical instruments, appliances, [illegible] diplomas of British and foreign [illegible] be for curiosities of pharmacy— [illegible] ts and price lists; (G) [illegible] vertisements; (H) ancient pharmacy signs, early shop fittings, and appliances; (I) early pharmaceutical specialities and specimens of obsolete and curious medical combinations; and (J) old travellers' advice books, curious orders, &c. Section 7 will be for curiosities of allied sciences: (A) ancient herbaria, abnormal plant forms; (B) curious magnetic and electrical appl[illegible] (D) historical chem[illegible] pological exhibit; [illegible] (I) biological exhib[illegible] exhibit.

If any of our readers possess any of the articles mentioned Mr. Wellcome hopes that he may count upon their assistance by lending them to him. His letter to us concludes: "I need hardly say that great care will be taken of all objects sent on loan and they will be insured. If desired, I will also insure specially valuable articles while in transit. Packing and carriage, both ways, will be paid by me. Hints and suggestions in connexion with the exhibition will be much appreciated." Such an exhibition can hardly fail to be of great interest to all medical men.

DEATH REGISTRATION IN THE UNITED STATES OF AMERICA.

BY a recent mail we have received from America a series of Government pamphlets issued by the United States Census Office with the object of promoting uniformity in the medical certification and classification of causes of deaths throughout the republic. From the preface to a "manual of classification" included in this series we learn that although civil registration of deaths has been already organised in many of the American States there are still a considerable number in which this provision—which in England we regard as essential to public safety—has not yet been established. It must, however, be recognised that in a republic consisting of many autonomous and practically independent States there are serious difficulties in the way of securing the necessary uniformity of law as well as of practice. Another difficulty which it will take some years to remove consists in the unsettled state of medical education and qualification which at present prevails in many parts of America. In Washington and in some other Transatlantic cities we believe that medical qualification, not less than medical practice, is satisfactorily regulated by law; but, unless we are misinformed, this is by no means the case in many other parts of America. Not until it becomes illegal, or at any rate discreditable, for an unauthorised person to assume the title and function of physician or surgeon will it be possible to provide for the due organisation of the medical profession throughout the United States and for the protection of the people against quackery and imposture. An important forward step has, however, been made and we heartily congratulate the census authorities of Washington on the energy and public spirit which they have shown in dealing with a complex but most necessary project for the welfare of the American people. The system of classification which has been adopted by the census authorities appears to be a modified form of the classification of Dr. Bertillon of Paris. It remains to be seen whether or not that system will be found to need revision from time to time. For our own part we should have thought that in a country in which the attempt is being made to establish for the first time a uniform record of vital statistics a shorter and far simpler list of diseases would have been more appropriate. In addition to the "manual of classification" of causes of death the series of census publications to which we have referred contains the following: (1) practical suggestions concerning a "standard certificate of death," with directions for its use and for the compilation therefrom of permanent records of mortality; (2) remarks on "the relations of physicians to mortality statistics"; (3) suggestions as to the statistical treatment of causes of death; and (4) details of legislative requirements for the registration of vital statistics. We have not space to notice these pamphlets severally in detail but from the rapid survey of them which alone has been possible we think that they are well calculated to further the objects which the census authorities have in view. In conclusion, we may express a hope that in course of time the national registration of causes of death in America will be accomplished with an accuracy approximating to that which has already been attained in many of the countries of Europe.

THE *Deutsche Medicinische Wochenschrift* has issued a festival number on the occasion of Professor Koch's sixtieth birthday, to which such leading bacteriologists have contributed as, among others, Professor Löffler, Professor Metchnikoff, Professor Roux, Professor Ronald Ross, and Professor A. Celli. Lord Lister has written a letter to the editor expressing his high appreciation of Professor Koch's scientific work and his regret that the state of his health will not permit him to make a longer communication to the festival number.

THE secretary of King's College Hospital has received a communication from the trustees of the Annie Zunz fund intimating their willingness to contribute £10,000 towards the removal fund "on the usual conditions of the bequest." The trustees imply that further contributions will be forthcoming towards the equipment and maintenance of the "Annie Zunz Ward."

THE authorities of Christ's Hospital have, it is stated, decided to sell the whole of the remainder of their site to the Post Office This scheme if carried through will obviously prevent any local extension of St. Bartholomew's Hospital except in the direction of the sky, as suggested by Mr. J. Y. W. MacAlister.

HIS MAJESTY THE KING has been graciously pleased to permit Dr James Donelan to accept and to wear the insignia of a Chevalier of the Order of the Crown of Italy, recently conferred on him by the King of Italy in recognition of his services as one of the physicians to the Italian Hospital.

A TELEGRAM from the Acting Governor of the Mauritius received at the Colonial Office on Dec. 18th states that for the week ending Dec. 17th there were 83 cases of bubonic plague and 49 deaths from the disease.

THE plans for the erection of the Royal Army Medical College on the Thames Embankment at Millbank have, we understand, now been formally approved.

THE Local Government Board for Scotland intimates that during the period from Dec. 1st to 15th inclusive 96 cases of small pox have been reported.

THE RESEMBLANCES BETWEEN THE CELLS OF MALIGNANT GROWTHS IN MAN AND THOSE OF NORMAL REPRODUCTIVE TISSUES.

Professor J. B. Farmer, F.R.S., Mr. J. E. S. Moore, F.L.S., and Mr. C. E. Walker communicated a paper to the Royal Society on Dec. 10th in which they gave the results of their joint investigations into the nature of malignant growths occurring in man. The account of what the authors have observed will be considerably elucidated by a brief recapitulation of the different ways in which the cells of an organism proliferate, as the value of the deductions from their observations depends to a great extent upon the differences between the manner in which the somatic cells—that is, the cells forming the ordinary tissues of the body—and those which are destined to form reproductive tissue divide. To emphasise the similarity existing between malignant tissue and the normal tissues of the sexual reproductive glands the authors propose to introduce the term "gametoid" to express the former and "gametogenic" the latter. When the egg of an animal or plant segments so as to give rise to an organism the nuclei of all the cells are found, when dividing, to contain a definite number of rod-like bodies known as chromosomes, this number remaining constant throughout subsequent divisions. Besides remaining constant in number, however, the chromosomes pass through a very definite series of evolutionary changes. At first the material out of which the chromosomes originate appears as granules of stainable substance (chromatin). Then, after certain characteristic stages, this substance takes the form of chromosomes, of which the number proper to each animal or plant is constant. During the process of division each of these chromosomes splits longitudinally into two daughter chromosomes which at this period are arranged in a very definite manner upon the spindle, frequently appearing as V's with the apices towards its axis (Fig. 1). The daughter nuclei are formed by the distribution to either pole of the spindle of the respective halves of each original chromosome. The nuclei thus formed may now enter upon a period of rest. Whenever new *somatic* cells are formed in the body the nuclei pass through identically similar phases. But in every individual there are certain cells which eventually give rise to the gametogenic elements, not to the specialised somatic tissues. Such cells, whether they appear early in embryonic life, or later during the life of the individual, always present very marked difference in their mode of division and in their subsequent history. These differences first become apparent as the cell commences its preparation for division. Those cells which are about to produce the gametogenic elements present a highly peculiar appearance, and at a definite stage in the multiplication pass through a cycle of changes wholly different from that passed through by the cells of the surrounding tissue and also from the changes occurring in those cells from which they themselves have sprung.

FIG. 1.

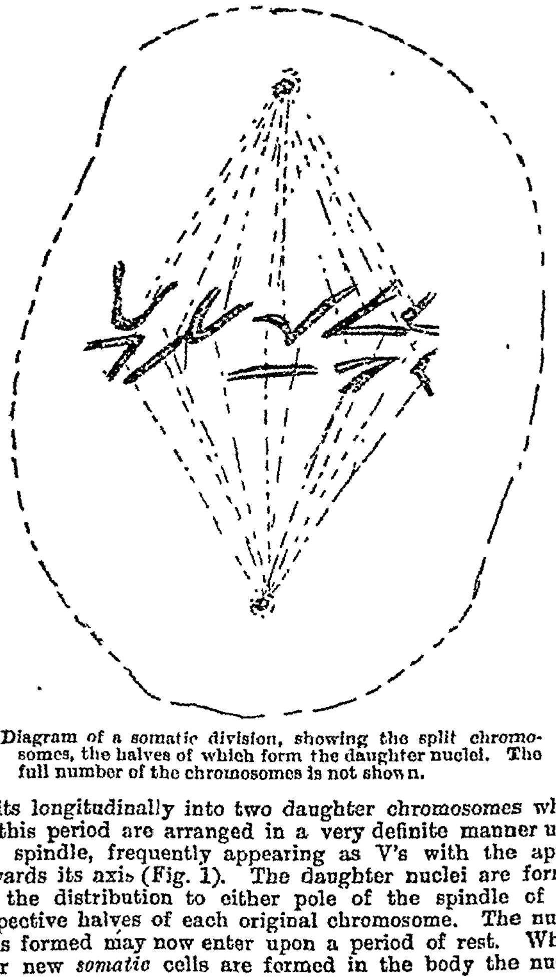

Diagram of a somatic division, showing the split chromosomes, the halves of which form the daughter nuclei. The full number of the chromosomes is not shown.

To the particular form of division (mitosis) associated with this metamorphosis the term "heterotype" has been applied and it is a characteristic and interpolated stage in the reproductive cycle of all sexually propagating animals and plants. Cells from which the heterotypically dividing elements will finally emerge can often be distinguished from those which will produce somatic tissues. In the testis of a mammal or in the sporogenous tissue of a stamen the existence of these cells may be recognised with ease and certainty. They continue to multiply and though differing from the adjacent cells in many respects resemble them in their mode of division until they pass severally into that peculiar state of growth that ushers in the heterotype division. The essential features in which this heterotype mitosis differs from the somatic mitosis (that of the cells forming the soma or body of the plant or animal), as well as from those in the cell generations of the reproductive tissues that have preceded it, are as follows: 1. A period of rest and growth. 2. The chromosomes when they are formed from the resting nucleus are present in only half the number of those occurring in the rest of the dividing nuclei of the organism. 3. The forms exhibited by the chromosomes are strikingly different from those of other nuclei. They present figures resembling loops, rings, aggregations of four beads, and so on. 4. They are arranged longitudinally upon the spindle. Their division on the spindle is apparently always transverse and not longitudinal, for even in examples where the separation might be interpreted as longitudinal fission the process as actually passed through differs markedly from the ordinary longitudinal fission exhibited by the chromosomes of every other mitosis. It will thus be seen that the heterotype mitosis is an easily recognisable phase in the history of the development of the gametogenic cells (Fig. 2).

It is a fact of the highest importance that when once heterotype division has supervened all the descendants of that cell in normal cases retain the reduced number of chromosomes, the cycle closing with the formation of the definite sexual cells. It is on the fusion of two of these cells (ovum and spermatozoon) that the double number of chromosomes is restored, and this number is characteristic of the fertilised egg and of all the cells to which it gives rise until the heterotype mitosis again supervenes in the gametogenic tissues. After the intervention of the heterotype division the cell in which it has occurred may, after one further division, give rise to four sexual cells, as in the higher animals. On the other hand, in the majority of plants a varying number of cell generations with the reduced number of chromosomes may be intercalated before the final differentiation into the sexual elements. The organism thus arising is very commonly parasitic in character, invading the somatic tissue of the plant.

A systematic investigation of the cytological features of malignant growths in man, conducted by the authors, has revealed the existence of a surprising degree of similarity between the phases that characteristically recur in these growths and the transformations from somatic into reproductive cells as just described. Thus in a typical example of epithelioma they found that in the early stages of proliferation of the Malpighian layer the cells of the invading tissue at first pass through a cycle of somatic divisions, exactly as occurs during the early stages of the formation of normal gametogenic tissue. As cell multiplication proceeds, however, a change passes over the cells themselves. The protoplasmic continuity, to which their "prickly" character is due, becomes obliterated and the cells assume that appearance of *indifferent* germ tissue so well known as a feature of the elements of which malignant growths are largely made up. Besides this a varying number of cells were observed, ten situated in an ill-defined zone behind the growing lge of the advancing neoplasm, which had attained mewhat large dimensions. Each contained a nucleus hich had grown to a considerable size. In those which d entered upon a prophase of division it was

FIG. 2.

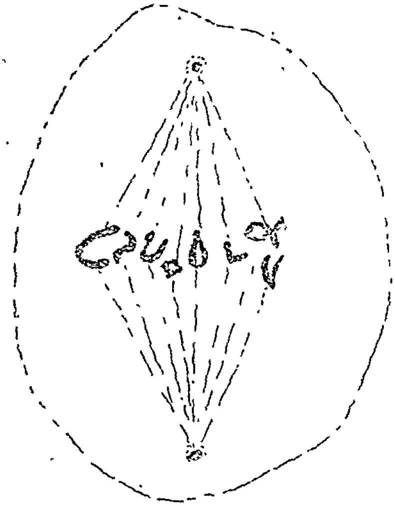

Diagram of a heterotypical division, showing the characteristic rings and loops which split transversely to form the daughter elements. As in the former figure the full number of chromosomes is not shown.

ognised that the chromosomes instead of appearing as licate thin rods or V's split longitudinally, presented the earance of short, thickened loops or rings, closely re- bling the later prophase stages of the heterotype mitosis the normal gametogenic tissues. Still more significant the fact that in these cells the number of the omosomes was obviously less than in the normal somatic ls or the surrounding tissues. In many cases it was ermined that the numbers were approximately halved; l furthermore, it was clear that the loops and rings racteristic of this stage of the cellular development malignant growths were arranged lengthways on the ndle and so were ultimately divided transversely, exactly in the corresponding heterotype mitosis of the repro- ctive elements. Subsequent divisions appeared to re- ble the somatic form but retained the reduced number chromosomes (homotype division). The authors par- ularly emphasise the fact that the cells that they cribe are in *no sense embryonic in character,* though y have so frequently been described as such in the past. bryonic cells have the potentiality of the full normal nber of chromosomes and exhibit them when in process livision.

rregularities of various kinds are mentioned. Amitosis is l to be of frequent occurrence, as it is also, for instance, he normal testis of a young monkey. The number of the omosomes in the cells which had continued to divide otically frequently exhibited irregularities. The authors, vever, claim that these facts do not seriously affect their ition, for in many other cases similar irregularities occur post-heterotype cells when these fail to give rise to ual sexual reproductive elements. They state that this cription of cellular and nuclear changes applies not only epithelioma but also in all important details to other cinomata and to sarcomata. They explain that when ing the process of development a considerable amount of natic tissue is formed in a malignant tumour it is obvious t a corresponding proportion of the cells have never lergone heterotypical division. Thus in such tumours scirrhus of the breast, cells showing heterotype figures more difficult to find than is the case in rapidly growing nours where but little somatic tissue is produced.

It is thus *pointed out* that in a most important respect the various malignant tumours present certain common features, and that these features are similar to those observed in the *normal process* of differentiation of reproductive cells. The authors feel themselves justified in deliberately correlating the appearance of these malignant growths with the result of a stimulus which has changed the course of somatic cell development into that characteristic of gametogenic tissue. They look upon this transformation as representing the immediate cause of the malignancy of the growths in which they are found. The remote causes [illegible] physiological stimuli—[illegible] tion—known to favour [illegible] nsider that malignant growths are definitely distinguishable from benign tumours, for in the latter they have not succeeded in discovering anything resembling the very characteristic nuclear changes described above.

Such questions as the probable transmission of the disease and its prevalence in certain localities were merely touched upon. The authors, however, deemed it probable that actual contact may in some cases transmit the disease and it seems likely that this happens where living cells from the growth are transplanted to another part of the same individual or to another individual under very peculiar conditions which allow of the continuous application of a suitable stimulus and the continuous introduction of cells [illegible] where malignant growths are apparently prevalent—e.g., cancer houses—the phenomenon is directly comparable to the occurrence of abnormal cellular developments under suitable stimuli which have already been referred to.

In conclusion, the authors point out that the various [illegible] cells are always rapid and [illegible] approaching death of the [illegible] ssues are treated in such a manner as to fix and to preserve the cells some time before death supervenes the nuclei will be found either in a state of rest or more or less disintegrated. They emphasise this fact because in the ordinary pathological methods of preparing specimens it has hitherto not always been thought necessary to make the proper provision for the preservation and fixation of the cells, either with regard to time or suitable reagents. Such preparations, though of course admirably suited for ordinary histological investigation, are not suitable for the elucidation of the finer cytological characters of the individual cells.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE following is a list of the grants and donations made by King Edward's Hospital Fund for London for the year 1903, with the comments of the distribution committee:—

Alexander Hospital for Children, £500; Belgrave Hospital, £750 to building, Blackheath and Charlton Cottage *Hospital, £60* to equipment of operating room, Bolingbroke Hospital, £1000—£500 to improvements; British Lying-in Hospital, £250; Cancer Hospital, Fulham-road, £200 Central Londc [illegible] Central London Throat and Ear [illegible] by this Fund; Hospital for Women, Soho-square, W., £1000 annual to maintain beds reopened by this Fund; Hospital of St. John and St. Elizabeth St. John's Wood, £500 annual to maintain beds reopened by this Fund; [illegible] annual to maintain beds reopened by this Fun [illegible] and Children's Hospital, W. (not eligible as a [illegible] ation); King's College Hospital, £6500 and £1000 annual to meet deficiency, £1500 for general maintenance, £5000 to the fund for removal of the hospital to South London which the committee view with great satisfaction; London Fever Hospital, Islington, N., £600; London Homœopathic Hospital, £200; London Hospital, £2000 and £5000 annual to meet expenditure out of capital made necessary by improvements in the wards; London Lock Hospital (Female), £600; London Temperance Hospital, £500 for out-patient department, conditional on the work being put in hand during 1904; London Throat Hospital, £50; Medical Mission Hospital (formerly entered as Cottage Hospital, Canning-town), Plaistow, £550—£250 to building; Memorial Cottage Hospital, Mildmay-park, N., £50; Metropolitan Hospital, £2000 and £500 annual to maintain beds reopened by this fund; Middlesex Hospital, £1500 and £1000 annual to meet deficiency (the committee note with satisfaction abolition of the practice of keeping butter in the lockers by beds); Mildmay Mission Hospital, £250; Miller Hospital, £1000 to building; Mount Vernon Hospital for Consumption (formerly entered as North London Hospital for Consumption), £500 and £1000 annual to support beds reopened by this Fund; National Dental Hospital, £50; National Hospital for Diseases of the Heart, £50 towards x-ray apparatus; National Hospital for the Paralysed and Epileptic £750 and £750 annual to meet deficiency, £500 to improvements; National Orthopædic Hospital, £400 (committee view with satisfaction the amalgamation with the Royal Orthopædic Hospital); New Hospital for Women, £300; North-Eastern Hospital for Children, £1000 and £500 annual towards maintenance, £1000 for building; North-West London Hospital, £750 (committee urge the rebuilding of this hospital); Norwood Cottage Hospital, £50; Paddington-green Children's Hospital, £400; Passmore Edwards's Acton Cottage Hospital (committee are glad to say that it does not require help from the Fund this year); Passmore Edwards's Hospital, East Ham, £50; Passmore Edwards's Hospital for Willesden (committee are glad to say that it does not require help from the Fund this year); Passmore Edwards's Cottage Hospital, Wood-green, N., £50; Poplar Hospital, £500 annual to help to open closed beds; Queen Charlotte's Lying-in Hospital, £500; Queen's Jubilee Hospital, Richmond-road, S.W., £200 to building fund (committee consider a new hospital urgently required in this district); Royal Dental Hospital of London, £300 to debt on building; Royal Eye Hospital, £250; Royal Free Hospital, £2000 and £750 annual to meet deficiency, £1500 towards improvements; Royal Hospital for Children and Women, £1000 for building; Royal Hospital for Diseases of the Chest, £500 towards the open-air sanatorium; Royal London Ophthalmic Hospital, £2000 annual, £2500 donation to help to maintain the beds opened by this Fund (committee consider this hospital should receive more support from the public); Royal Orthopædic Hospital, £200 (committee view with satisfaction the amalgamation with the National Orthopædic Hospital; Royal Westminster Ophthalmic Hospital, £400 to debt; St. George's Hospital, £2000; St. John's Hospital for Diseases of the Skin, £50 to Shepherd's Bush Branch; St. John's Hospital, Lewisham, S.E., £100; St. Mark's Hospital, £100; St. Mary's Children's Hospital, Plaistow, E., £600; St. Mary's Hospital, Praed-street, £1000 and £1000 annual to meet deficiency; St. Monica's Hospital, £50; St. Peter's Hospital for Stone, £100; St. Saviour's Hospital, Regent's park, N.W., £100; St. Thomas's Hospital, £1800 to maintain the beds reopened; Salvation Army Maternity Hospital, £50, Samaritan Free Hospital £200 and £500 annual towards maintenance, £200 to new out-patient department; Santa Claus Home, Highgate, N., £50 in consideration of the fact that curable cases are admitted; South Wimbledon and Merton Cottage Hospital, £50 for operative appliances; Tottenham Hospital, £2000 and £1000 annual to maintain beds reopened by this Fund, £2000 to building; University College Hospital, £2000 and £1000 annual to support beds reopened by this Fund; Victoria Hospital for Sick Children, £800; West-End Hospital for Diseases of the Nervous System, £150 towards isolation ward; Western Ophthalmic Hospital, Marylebone-road, no grant (to be reconsidered when proper progress had been made towards collecting the rebuilding fund), West Ham Hospital, £2000 and £300 annual towards maintenance, £2000 building; West London Hospital, £1000 and £1500 annual to maintain beds reopened by this Fund, £1000 conditional on the bath-rooms, &c., on east side being put in hand at once; Westminster Hospital, £1000 and £750 annual towards deficiency; and Woolwich and Plumstead Cottage Hospital, Shooter's Hill, Kent, £50.

A special grant of £10 500 has been set aside to be drawn on as required for the amalgamation of hospitals.

The awards recommended for convalescent homes are as follows:—

Alexandra Hospital, Painswick, £50, Charing Cross Hospital, Limpsfield, Surrey, £50; East London Hospital for Children, Bognor, £100; King's College Hospital, Hemel Hempstead, £100; Mary Wardell Home, Stanmore, Middlesex, £50; Metropolitan Hospital, Cranbrook, £25; Metropolitan Convalescent Institution, Piccadilly, W., £200; Middlesex Hospital, Clacton on-Sea, £100; Mrs. Kitto's Home, Reigate, £25; [illegible] e Paralysed and Epileptic, East Finchley, £50; [illegible] ildren's Hospital Slough, £50; Queen Char[illegible], Kilburn, £50, St. George's Hospital and Atkinson Morley's Convalescent Hospital, Wimbledon, £50; St. Mary's Hospital, for Sick Children, Southend-on Sea, £50; and Victoria Hospital Broadstairs, £50.

ASYLUM REPORTS.

London County Asylum, Banstead (Report for the year ended March 31st, 1903).—The average number of patients resident during the year was 2453, comprising 1076 males and 1377 females. The admissions during the year amounted to 503—viz., 271 males and 232 females. Of these 440 were first admissions. Dr. D. Johnston Jones, the medical superintendent, states in his report that as to the mental disorder of those admitted there were more cases of melancholia than in former years, 32 per cent. of the males and 40 per cent. of the females belonging to this class. Regarding causation alcoholic intemperance was the predisposing or exciting cause in 20 per cent. of the males and 12 per cent. of the females. The number of patients discharged as recovered during the year amounted to 210, or 8 5 per cent. of the average number resident. The deaths during the year amounted to 252, or 10·2 per cent. as calculated on the same basis. Of the deaths five were due to renal disease, seven to cancer 14 each to pneumonia and senile decay, 15 to epilepsy, 44 to pulmonary tuberculosis, 68 to general paralysis of the insane, and the rest to other causes. Among the minor casualties were six cases of simple fracture and two dislocations, all due to falls, and all were successfully treated. The general health of the institution has been satisfactory. Small-pox broke out in May and 12 patients were attacked. Two of these died and the rest recovered. "The disease was apparently introduced by a visitor to a sick patient in Ward A2 who had come from an infected district." "All cases of phthisis are now notified and kept as far as possible in one ward." The Commissioners in Lunacy state in their report that the general appearance of the patients was satisfactory, that the day-rooms were bright and cheerful, that the dormitories and bedding were clean and in good condition, and that the medical case-books and records were very carefully kept. The committee of management states in its report that the farm and field crops have all been good and that the total profit from the farm for the year has been £314. The amount expended on ordinary repairs executed at the asylum was £8080 and on additions, alterations, and improvements £388

Egyptian Hospital for the Insane, Cairo (Annual Report for 1902).—The report just published of the Egyptian Government Hospital for the Insane, Cairo, for the year 1902 states that the number of cases of insanity treated in the institution during the year amounted to 859 Owing to the increasing number of insane patients requiring admission Dr. John Warnock, the medical superintendent, states that the construction of a new asylum will be necessary. Owing to limited accommodation at present many unrecovered patients have to be discharged to make room for patients urgently needing admission, a condition which, coupled with the increasing numbers of the insane, is, says Dr. Warnock, "a menace to public security." "Many of the patients who are discharged while still insane proceed to beget *families*, ... thus swelling the ranks of paupers and transmitting their insanity to their children." Insanity in Egypt is regarded as a reason for marriage. "When a young man becomes insane one of the first steps often taken is to marry him to some woman who often becomes pregnant before her husband's insanity necessitates his confinement in the asylum." The Cairo Asylum is now lighted with electric light while its water-supply and ventilation are found to be both efficient and modern. Many useful handicrafts are taught in the institution such as cloth, basket, and mat making, while the more tranquil patients are employed in farming and gardening. Owing to the absence of special legislation for lunatics in Egypt the questions of care and treatment and of lunacy procedure rest on no certain basis and Dr. Warnock recommends that some legislation modelled on the line of the English Lunacy Act of 1890 should be introduced. The number of patients discharged as recovered during the year amounted to 120. The deaths during the year amounted to 67. Of the forms of insanity in the cases admitted the following occurred in descending order of frequency, viz.: acute mania (133 cases), insanity from hasheesh, chronic mania, pellagrous insanity, and melancholia (29 cases) out of a total number of 408 admissions. Among the more potent causes of insanity in the admissions Dr. Warnock enumerates hasheesh, hereditary predisposition, pellagra, syphilis, and alcohol.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Deputy Inspector-Generals: Howard Todd to Haslar Hospital (dated Dec. 5th, 1903) and W. E. Breton to Bermuda ospital (dated Dec. 16th, 1903). Fleet Surgeons: J. J. innis to the Royal Marine Infirmary, Deal (dated ec. 28th, 1903) and R. Miller to the *President*, additional ated Dec. 16th, 1903). Surgeons: W. H. O. Garde to aulbowline Hospital, G. Ross to the *Albion*, and J. A. iompson to the *Drake* (dated Dec. 11th, 1903); D. W. ewitt, lent for service at the Admiralty (dated Dec. 14th, 03); T. D. Halahan, lent to Royal Naval Engineering [illegible]; G C. C. Ross to [illegible]. Chapman to the [illegible] he *Speedwell*, R [illegible] nnedy to the *Hebe*, and J. H L. Page to the *Spanker*, lent (dated Dec. 16th, 1903). Civil Practitioner J ffin to be Surgeon and Agent at Stokes Bay (dated c. 15th, 1903).

Deputy Inspector-General of Hospitals and Fleets Charles ne Godding has been promoted to the rank of Inspector-neral of Hospitals and Fleets in His Majesty's Fleet ited Dec. 5th, 1903), Fleet Surgeon Howard Todd has en promoted to the rank of Deputy Inspector-General Hospitals and Fleets in His Majesty's Fleet (dated c. 5th, 1903).

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned have been appointed Surgeons:—Mr. lliam James Tivy and Mr. Walter Kenneth Wills.

ROYAL ARMY MEDICAL CORPS.

Brevet.

The undermentioned Lieutenant-Colonel to be Colonel:— rid Bruce, F.R.S., R.A.M.C., in recognition of his vices in investigating the cause of the "sleeping kness" in Uganda, as well as in consideration of the inction already attained by him in researches connected h Malta fever and tsetse-fly disease (dated Dec. 10th, 3).

Captain T. H. M. Clarke, C.M.G., D.S.O., from the onded List, to be Captain (dated Nov. 30th, 1903). onel J. F. Supple, C.B., is placed on retired pay (dated c. 14th, 1903). Lieutenant C. H. Robertson resigns his mission (dated Dec. 19th, 1903).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Home District (late Middlesex) Company: Supernumerary itenant (Honorary Lieutenant in the Army) G. J. D. *ies to be Captain (dated Dec. 19th, 1903).*

ARMY MEDICAL RESERVE OF OFFICERS.

urgeon-Lieutenant A. Mackenzie, 3rd Volunteer Battalion Prince of Wales's Own (West Yorkshire Regiment), to Surgeon-Lieutenant (dated Dec. 16th, 1903); Surgeon-tain J. Shaw, having resigned his commission in the unteers, ceases to be an officer in the Army Medical erve of Officers.

VOLUNTEER CORPS.

oyal Garrison Artillery (Volunteers): 1st Banff: geon-Major W. Fergusson to be Surgeon-Lieutenant-onel (dated Dec. 19th, 1903).

ifle: 2nd Volunteer Battalion the Royal Warwickshire iment: Brigade-Surgeon-Lieutenant Colonel C. Dukes, ior Medical Officer, Worcester and Warwick Volunteer ntry Brigade, resigns his commission and is granted the orary rank of Surgeon Colonel, with permission to wear prescribed uniform on retirement (dated Dec. 19th, 3). 3rd (Cambridgeshire) Volunteer Battalion the Suffolk iment: Surgeon-Lieutenant A. W. Clark resigns his commission (dated Dec. 19th, 1903). 4th (Perthshire) Volunteer alion the Blac [illegible] rgeon-itenant W. Haig [illegible] 19th, 3). 1st Volunte [illegible] Vales's yal Berkshire [illegible] officer gns his commi [illegible] asman ed Dec. 19th, 1903).

VOLUNTEER INFANTRY BRIGADES

ampshire: Surgeon-Major E. J. Hunter, 3rd Volunteer talion the Han [illegible] itenant-Colonel [illegible] lical Officer to [illegible]

YAL ARMY MEDICAL CORPS (VOLUNTEERS) (GLASGOW COMPANIES) ANNUAL.

he third number of this annual is in point of excellence way behind its two predecessors. It deals with subjects interest not only to the particular corps from which annual takes its name but to Volunteer medical corps generally. In addition to the more weighty contributions, including papers on the Glasgow Division R.A.M.C. (V.) under Mobilisation, the Camp of the Transport Section at Aldershot, and the Camp at Netley, there are several articles and illustrations of a humorous nature. Among the illustrations are reproductions of photographs of Surgeon-General Sir William Taylor, K.C.B., Director-General of the Army Medical Service; Lieutenant Colonel W. Babtie, V.C., C.M.G., Assistant Director-General; and Lieutenant-Colonel E. M. Wilson, C.B., C.M.G., D.S.O., Deputy Assistant Director General. The price of the annual is 3*d*. and the publishers are Messrs. John Horn, Limited, 34, Howard-street, Glasgow.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF CERTAIN FORMS OF OBSTINATE CONSTIPATION BY ENTERO-COLOSTOMY.

To the Editors of THE LANCET.

SIRS,—With reference to your note on Mr. W. Arbuthnot Lane's case in which he effected "a lateral anastomosis between the end of the ileum and the first piece of the rectum" and thereby relieved a patient who was habitually constipated owing to intraperitoneal adhesions, may I point out that an operation of this kind might reasonably be tried in certain cases of chronic constipation in which no adhesions or other mechanical obstruction existed?

In the summer of 1901 I suggested an anastomosis between the lower end of the ileum and the sigmoid flexure in a case then under the care of Dr. Daniel Lehane of South Kensington as well as of Dr. W Bezly Thorne. The patient, a tall, well-made young man, wished me to perform on one of his legs an operation which I knew would be futile and which was unnecessary. He was evidently suffering from neurasthenia and hypochondriasis and in danger of gliding into something worse. One feature of his case was most obstinate constipation. He was not willing to adopt commonplace and often effectual measures against that trouble and he was not only willing, but anxious, to have *some* operation performed. I suggested to him, without pressing, that I should short-circuit his intestine by uniting the lower end of his ileum to his sigmoid flexure. I thought this proceeding, by removing his constipation in a radical manner, would cause him to see life in a more roseate colour and dispose him to look less closely into his real or supposed bodily ailments. However, he found an eminent surgeon who operated for some small varicose veins. Of his ultimate state I have heard nothing.

I cannot help thinking that this mode of treatment should be seriously considered in the cases of many persons who combine obstinate constipation with the following conditions: (1) hypochondriasis and neurasthania, especially when, as in Dr. Lehane's and Dr. Bezly Thorne's patient, it borders on even a worse mental state and imperils the patient's position in his profession; and (2) some of those cases of chronic gastric trouble in young women in which intractable constipation is a marked sign and in which the presence of peptic ulcer is very doubtful. I am of opinion that in a few of these ca [illegible] than a gastro enterostom [illegible] only case of gastro-ent [illegible] have yet lost belonged [illegible]

It is better to unite the ileum to the sigmoid flexure than to the rectum for the following reasons: (1) the sigmoid can usually be brought outside the abdomen and the operation of intestinal anastomosis is thereby made quicker, easier, and safer; and (2) if the junction is with the rectum occasions may occur when the patient will find it objectionable to have the liquid contents of the small intestine flowing into the rectum straight above the anus. The latter is, of course, an *a priori* consideration and experience might prove it erroneous, but of the advantage of delivering the intestine externally before suturing it there can be no question. There remains the question of lateral *versus* "end-to-side" anastomosis. That could be settled finally by experience only, but "end-to-side" would prevent fæcal

In Calcutta the new plague administration has recognised the value of inoculation and has publicly announced facilities for taking advantage of its benefits. The apathy of the people is so extraordinary that inoculation is not expected to be carried out on a large scale but convenient opportunities of being inoculated are to be provided, and that is a considerable advancement on previous policy.

The smoke nuisance has of late years become almost as great in Calcutta as in some of the manufacturing towns of England and an expert has recently submitted a report concerning its abatement. The excessive smoke in Calcutta is mainly due to the mills and the factories and it is estimated that 3·2 tons of solid carbon are emitted every 24 hours within a radius of five miles from Government House. There seems to be no remedy except by legislation and rules are suggested with regard to the various furnaces, fires, and chimneys. As the corporation is an offender equally with the factories it is probable that the Government will be compelled to take the matter in hand. The evil is increasing and is at present absolutely uncontrolled.

Nov. 27th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Disqualification of a Medical City Councillor.

Dr. C. A. Hill, who was elected a member of the city council for Abercromby Ward at the recent November elections, was subsequently disqualified owing to an unfortunate technicality. Dr. Hill held the appointment of lecturer on hygiene to the pupil teachers in the service of the late Liverpool school board, the functions of which had been taken over by the education committee of the city council. The fact of his being ineligible (by reason of his holding that office) as a candidate for civic honours did not occur to him until after the result of the election. He has since formally resigned his seat and it is not expected that he will be opposed on again seeking the suffrages of the electors of the ward. He has also resigned his lectureship.

Jottings from the Health Committee.

The health committee of the city council has recently sustained a severe loss by the death of Alderman Herbert Campbell, which occurred suddenly on Dec. 8th while engaged in a visit of street inspection.—Alderman Dr. Thomas Clarke has resigned the chairmanship of the port sanitary and hospitals committee, a post which he has filled with much credit to himself and advantage to the city for the past eight years. Pressure of professional duties led to his resignation.—The health of the city continues good. The deaths from zymotic diseases during the week ending Dec. 12th show the lowest rate of mortality from this class of disease during any one week for the last ten years. The prevalence of small-pox in Smyrna has during the last few months been a source of much anxiety to the port sanitary authority, five vessels in succession bringing cases of small-pox from that port. At the present time the city remains free from the disease, a suspected case being isolated.—A change in the *personnel* of the housing and insanitary property committee has recently taken place, the chairman and deputy chairman having resigned their positions.

Birkenhead and Wirral Children's Hospital.

Owing to the recent extension of this hospital the committee announces that funds are earnestly needed. The hospital is doing a most useful work and deserves support. In 1902 the number of in-patients was 540 and the out patients numbered 6234 The expenditure last year was £1625, as against £1325 in 1884 when the number of in-patients was only 286.

Dec. 21st.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Epidemic of Small-pox.

THE counties of Northumberland and Durham are at the present time suffering from a rather serious epidemic of small-pox. Most of the cases have been traced to tramps coming from other districts, pointing to the necessity not only of the registration of tramps, but also of some restrictions to the admission of unvaccinated tramps common lodging houses and workhouses. During current year there have been well over 100 cases in the of Newcastle, while the number of cases in the country tricts of Northumberland has greatly exceeded this fi In Gateshead the epidemic seems rather to be in than diminishing, because the number of cases at prese the Sheriff Hill Hospital is about 40 and fresh case being admitted almost every day.

Newcastle City Hospital for Infectious Diseases.

Owing to the rapid growth of the city of Newcastle the present hospital at Walker Gate was built the council has now under consideration a scheme fo enlargement of this hospital, not only to meet pr requirements but also to be prepared with sufficient ac modation in case of any sudden emergency. It is pro to spend the sum of £53,000 on these extensions, whicl include increased accommodation for both free and p patients and a separate block for the reception and disc of patients.

Annual Dinner of the Past and Present Students o College of Medicine, Newcastle-on-Tyne.

The above annual dinner is arranged to take place a County Hotel, Newcastle-on-Tyne, on Friday, Jan. 1904, at 7.15 P.M. Professor F. Page will occupy the while the warden of the University of Durham Kitchin) and other eminent guests are expected present. It is hoped that as many past and p students of the college as possible will endeavour to a

(FROM OUR OWN CORRESPONDENTS.)

Increased Cost of Cardiff Paupers.

Mr. F. T. Bircham, the Poor-law inspector for Wales, more than a year ago animadverted upon the ing increase in the expenditure of the Cardiff boa guardians, with especial reference to the cost of relievi outdoor poor. In ten years the population of the unic increased by about 25 per cent., but the number of o paupers had increased nearly 60 per cent. and the diture had gone up from £14,706 to £26,175, equal to crease of about 90 per cent. From the remarks whicl made by the same inspector to the members of the (board on Dec. 5th last it would appear that the ex ture in the union is still much higher than it shou for while the amount of pauperism has decreased extent of 4 per cent. in South Wales and Monmou there has been an actual increase of 14 per cent. in where also the expenditure has increased 66 per cent pared with an increase in the larger area of only 10 pe Mr. Bircham advised the board to equalise the size relief districts and to see that there is a sufficient nu officers to carry out the work properly, for every should have time to investigate all his cases. He t that scores of people would be found in the Cardif receiving relief who should not receive it and he re the board that the more strict it was with the unde cases the more money it would have for the deserving

Bristol Corporation and Winsley Sanatorium.

When the scheme for the establishment of the Sanatorium was projected the corporation of Bristol responsible for a proportion of the cost by contrib capital sum of £1000 and by undertaking to pay a furt of £260 annually. For these payments four beds a reserved for Bristol patients, but it was considered time when the arrangement was made that this would be utterly inadequate to the needs of the (there was a disposition on the part of several pr members of the health committee to establish torium exclusively for Bristol patients. In Jan this year the medical officer of health, Dr. D. S. submitted a report on the subject in which he that the cost of erecting a sanatorium varie £200 to £300 per bed and that the weekly maintenance for each patient would be from 35s. to 4 cost therefore of erecting a sanatorium for 50 patie maximum number Dr. Davies considered desirable in one building—would be from £13,000 to £15,0 hese sums if borrowed and repaid in 30 years would entail n annual expenditure of about £700 and £800 respectively. he annual cost of maintenance would amount to about 4000. A subcommittee very carefully considered this eport but eventually recommended the corporation to contribute a further capital sum of £4000 and an annual sum f £1040 to the Winsley sanatorium on the understanding hat 20 beds should be allotted to the city of Bristol. The orporation has adopted this recommendation but with the ight to transfer its interest in the institution if it so desires.

Superannuation of Dr. H. T. Pringle.

The committee of visitors of the Glamorganshire County [illegible] H. T. Pringle's superannuation [illegible] num. Dr. Pringle has been con- [illegible] asylums for more than 37 years, [illegible] of which period he has been edical superintendent.

Swansea and the Spitting By-law.

The Swansea corporation has adopted the spitting by-law the terms which the Home Office is now prepared to anction: "No person shall spit on the floor, side, or wall f any public carriage, or of any public hall, public waiting- om or place of public entertainment whether admission ereto be obtained upon payment or not."

University College, Bristol.

A year ago there was a debt of £5000 in connexion with [illegible] en entirely [illegible] the Bishop [illegible] University [illegible] Bart., and ir Frederick Wills, Bart., M.P., each contributed £1000 wards the amount required. A further sum of £500 has ow been received from the managers of the Exhibition of elsh Industries recently held in Bristol, so that it is sible to complete the University buildings without increasing to any great extent the indebtedness of the overnors.

University College, Aberystwyth.

Mr. R. H. Yapp, M.A., of Cambridge, has been appointed ofessor of botany to the Aberystwyth College of the University of Wales in succession to Professor J. H. Salter, D.Sc. ofessor Yapp accompanied the Cambridge University ientific exploring expedition to the Siamese-Malay States the year 1899

Herefordshire General Hospital.

The late Mr. Attwood Matthews, who was the founder of [illegible] ft £5000 to the funds of the Hereford- [illegible] to be paid on the death of his widow. [illegible] ollection of a penny each month from actically every cottage in the county has resulted in the cumulation during the past nine months of a sum of nearly 650 which is to be handed over to the managers of the stitution.

Bacteriological Examinations.

The Wigmore (Herefordshire) rural district council, on e recommendation of the medical officer of health (Mr. A. T. Cartwright), recently asked the Herefordshire county uncil to follow the excellent example of the neighbouring unty councils of Worcestershire and Shropshire and to ake arrangements for bacteriological examinations to be rried out in cases of doubtful diphtheria, &c The council, owever, decided that there was not "sufficient warrant to commend the expenditure of county funds in the way ggested."

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Glasgow.

Dr. A. K. Chalmers, the medical officer of health of the ty of Glasgow, in his report for the fortnight ending ov. 28th, states:—"45 cases of small-pox were removed to ospital during the fortnight in place of 19 during the preious one. Ten of these cases were removed from formerly fected models and three others had been in models when fection occurred. Among the number were five children nder ten years of age, in none of whom were vaccination arks discoverable. For comparative purposes it is desirable to group the distribution of the cases now occurring according to the old sanitary districts and this shows that of the total occurring during the fortnight 14 were in the eastern district, 12 in the central, nine in the south and south-suburban, seven in the north, and three in the west. Reference was made in the report for last fortnight to the difficulty in obtaining any extension of revaccination beyond the immediate neighbourhood of infected houses, but in view of the recurring excess (31 per cent) of cases in the eastern district the inspectors were, after consultation with the chairman, distributed, whenever the demands of their own districts had been satisfied, throughout this district with directions to make a house-to-house visitation and offer revaccination wherever it was required. This effort so far has only been attended by a moderate degree of success; indeed, as our past experience shows, until something akin to apprehension takes possession of the public mind the numbers who will resort to revaccination from purely prudential motives are comparatively few. Everything at the moment points to a period of considerable anxiety during the ensuing months. The engineers of Tweedsmuir Waterworks, near Broughton, were good enough to inform me during the past week of the occurrence of small-pox among the navvies employed there and they also added that some 40 or so of the men had left their addresses unknown although they anticipated that some of them might reach lodging houses in Glasgow. Subsequently, three of these men presented themselves at one of the lodging houses and on being told that admission could only be had on condition that they would be revaccinated they left, refusing to give any address. The part played by this portion of the population in disseminating small-pox has frequently been under review and it would be to the public advantage if some legislative method of following or controlling their movements existed Similar powers already exist in connexion with contacts with sea-borne infection of a certain type and it would only be an extension of an already recognised principle to apply similar powers to small-pox contacts under the circumstances alluded to."

The late Mr. Samuel Lawrence, M.D. St. And., L.R.C.S. Edin.

The death occurred at his residence, in John-street, Montrose, on the morning of Dec 18th, of Dr. Samuel Lawrence at the advanced age of 88 years. The deceased gentleman was the oldest medical practitioner in Forfarshire, having retired from practice only a year or two ago. After serving for a period under a qualified medical man he proceeded in 1832 to Glasgow and went through a course of three sessions at the University there. On completing his studies he, in 1834, went on a voyage to the Arctic seas as surgeon on a whaling ship and in 1834-35 contemplated another voyage which, however, he abandoned in favour of an appointment as an assistant in South Shields. Three months later the Edinburgh College of Surgeons conferred upon him its licence, after which he and a fellow student purchased their principal's practice and entered into partnership. Dr. Lawrence at that time was barely 20 years of age. Six years were thus passed, after which he went to Montrose in 1841, and for a period of 55 years was engaged in active practice. He was for a long time medical officer of the burgh of Montrose and a justice of the peace of the county of Forfar.

Cosmetics.

Professor Spiegler recently read before the College of Physicians a paper relating to the scientific principles of cosmetics The following is a summary of his remarks. How widespread and how ancient is the desire to beautify the outward appearance can be seen by the fact that even cannibals paint their bodies with bright colours, that the highly cultivated nations of antiquity have embodied explicit cosmetic prescriptions in their literature, and that even to-day the province of cosmetics represents a playground for that charlatanism to which human vanity is constantly offering up new victims In the way of cosmetics surgeons and orthopædists can do a good deal. Under the head of dermatology are included a number of external diseases the majority of which depend upon anomalies of constitution and which therefore need a general treatment. Among these diseases acne vulgaris is most frequent Patients suffering from this complaint invariably have a seborrhœic skin and many of them are somewhat anæmic. Constipation, too, is an etiological factor and there are many cases in which acne improves after massage of the abdomen or after internal medication with pulvis glycyrrhizæ compositus. It is well known that English women patronise sulphur on account of its complexion-improving qualities. The removal and prevention of intestinal decomposition are indispensable and therefore an abundant diet of fresh meat should be avoided. Strongly spiced dishes should likewise be forbidden. Local treatment is based upon the treatment of seborrhœa because dirt, dust, and the ubiquitous staphylococci adhere to the oily skin and are apt to produce an infection of the sebaceous glands. Large acne pustules should be opened. Acne rosacea is an illness of a more mature age than acne vulgaris; it is not always brought about by immoderate consumption of alcohol but frequently by disturbances of the digestion or at the climacteric. Hot fomentations for the purpose of restoring the tone of the blood-vessels should be employed locally. Anæmic young women and girls often have reddish or bluish-red noses which are moist and cool but on a change of temperature from cold to hot become hot and deep red; the same change is seen after meals and alcohol. Often the symptoms are due to slight congelations caused by wearing veils. The symptoms are based upon a local asphyxia caused by pareses of blood-vessels. The best remedy in this case is on the one hand prophylaxis (abolishing the veil), and on the other hand strengthening of the cardiac function and improvement of the anæmic state. The same state is observable in some young people in the fingers and the hands. Medical help is often required for pigmentations either on a physiological basis (pregnancy) or on a pathological basis. The increased pigmentation of the nipple diminishes in a short time in nursing women. Professor Spiegler reported the case of a lady who recognised her pregnancy before menstruation ceased through the increasing pigmentation of a nævus. Diseases of the female genitalia cause similar pigmentations. Some abnormal pigmentations are combined with liver complaints (cholelithiasis). Professor Spiegler has seen a patient with a characteristic pigment spot on the face which regularly disappeared after a course of treatment at Carlsbad and reappeared during the winter. The application of diluted acids, chlorine water (in severe cases), peroxide of hydrogen, or ointments of white precipitate is of use. The best prophylaxis against freckles is the wearing of red or reddish-yellow veils. Diseases of the hair and nails very often are in close connexion with internal complaints. Matsuura in Recklinghausen's Institute showed that in tuberculous or wasting diseases or in disorders of nutrition the hair gets thinner and later falls out. Likewise seborrhœa often causes the hair to fall out. The treatment of seborrhœa may in some cases improve and prevent the hair from falling out, but the seborrhœa remains improved only so long as the patient is under treatment. The great expectations which have been aroused for the treatment of hypertrichosis with Roentgen rays unfortunately have not been fulfilled and for the present the troublesome electrolytic treatment must be used for this purpose.

(From our own Correspondent.)

The Montreal League for the Prevention of Tuberculosis.

An active campaign against tuberculosis is being conducted by the Montreal League for the prevention of that disease. Recently the establishment of a dispensary in the city has been under consideration and it is proposed also that the league should have a sanatorium erected on Trembling Mountain which is contiguous to the city. A suitable site has been selected consisting of 450 acres and overtures are being made to the provincial Government, the owners thereof, who are being asked to set apart this tract of land for the purposes indicated. Since May 15th last the league has dealt with 103 cases and during the month of November about 79 cases were being supervised. The league is fathering a by-law before the city council regarding the prohibition of the spitting nuisance in the streets and in theatres, halls, and places of public worship. It is expected that this by-law will pass through the council by majority.

The Ottawa Medico-Chirurgical Society.

The Ottawa Medical Society and the Ottawa Society have become consolidated and the result Ottawa Medico-Chirurgical Society which held regular meeting on the evening of Nov. 5th. Sir Grant, M.D., is the honorary president and Dr. H. Small is the president. The first evening's program largely given over to the presidential address deli Dr. Small. This consisted of a series of biographical of Bytown's pioneer physicians, Bytown being the the capital of the Dominion of Canada prior to the Government being established there in 1867 and th changed to Ottawa. The address also dealt with the outbreaks of epidemics and the histories of the d hospitals. The society meets on the first and third Th of each month. The following are the officers in to those already mentioned: Vice-Presidents: Dr. Dewar and Dr. R. E. Webster. Secretary: Dr. Brown. Treasurer: Dr. H. S. Kirby. Curator: Dr. Royce. Librarian: Dr. James Seager. Council: Dr. Dr. R. S. Minnes, Dr. Troy, Dr. Echlin, Dr. Chabot, Basken.

A Bureau of Health for the Dominion of Canad

The Canadian medical profession through the medi their national medical organisation are anxious tha Canadian Government should create a separate depar of public health under the authority of one of the ex Ministers. The matter was first launched at the Mo meeting of the Canadian Medical Association in Septe 1902, when a resolution favouring the proposal unanimously passed by that association. As health m now stand orders are issued from several departments as Inland Revenue, Marine, Agriculture, &c. This i sidered anomalous and it were far better that all several branches should be grouped under the authorit competent head. The Canadian Medical Association special committee, consisting of Dr. R W. Powell of and Dr. T. G. Roddick, M.P., and Dr. E. P. Lachap Montreal, looking after the matter. It is understood th Hon. Minister of Agriculture, under whose authori Director-General of Public Health now acts, is very f able to the creation of this very important department

Changes in the Quebec Medical Laws.

If the will of the College of Physicians and Surge the province of Quebec can prevail with the Quebec lature then the medical course in that province will tended to five years. The College will also recommen British licences will hereafter not be recognised as equi to passing the examinations of the College. It will a recommended to the legislature that a B.A. degree *cours classique complet* should be adopted for matricul to apply, however, only to those studying in the F universities. The students of McGill University will particularly affected by this change.

Better Hospital Facilities required for Medical Edu in Toronto.

Now that the two leading medical colleges of the pr have become united in the city of Toronto and constitu medical department of the Provincial or Toronto Univ the faculty is seeking better hospital facilities for cl instruction. Towards this end a special committee c faculty has been visiting the hospitals of leading Am cities, such as Boston, New York, Philadelphia, Balt and Chicago, inquiring particularly into the conduct outdoor departments. The committee in charge o matter recently met the boards of the Toronto G and St. Michael's Hospitals, at which meeting Dr. Bradford, of University College, London, England, present, and addressed the assembled gentlemen. hospital work in London. As a result of the requireme the committee the house staffs will be better regul clinical, outdoor, and pathological work will be put u better basis, and better records will be kept than here All that the committee asks for has been in vogue in the Children's Hospital for some time.

The Birth-rate in Ontario.

The report of vital statistics for the province of O for 1902 has recently been issued. It shows that ther 47 796 births during that year as compared with 46, 1901, or an increase of 1735. The number of mari was 18,072, an increase of 37 over the previous year. number of deaths during the year was 27,864, while in the figures totalled 29,608, showing the substantial ase of 1744 Figured according to population the rate 1000 of births was 21·1 in 1901 and 21·7 in 1902; of iages in 1901, 8·2, and in 1902, 8 2; and of deaths in 13·6, and in 1902, 12·6. Dr. P. H. Bryce, secretary of Ontario board of health, attributes the increased birth- to the crusade instituted by the press of the country and ministers of all denominations against race suicide.

Obituary.

BERTRAM THOMAS READ, M.R C.S. ENG., L.R.C P. LOND.

HE death occurred on Dec. 12th of Mr. B. T. Read had been for the last five years in practice at Odiham, Winchfield, in Hants, and was much respected in neighbourhood. After leaving St. George's Hospital, re he received his medical training, he acted as surgeon the Royal Mail line for some time and eventually settled Odiham, where he was rapidly making a good practice held several appointments. On Monday, Dec. 7th, he ended the funeral of a patient and after doing his morn- round on the next day complained of acute abdominal n. Peritonitis was diagnosed. His father, Mr. T. L. ad, saw him on Thursday with Dr. H. D. Rolleston and it s seen that an operation was the only chance. Late that ht Mr. A. W. Mayo Robson performed the operation when ration of the appendix and perforation were found. e case was from the first a very severe one and in spite of that skill and care could do the end came on Saturday ning, Dec. 12th. Mr. Read will be deeply missed by all knew him and Odiham has lost a kind and skilful man always placed his patients' welfare before all else.

DONALD J. A. McLEOD, L.R.C.S. EDIN.

ON Dec. 5th there passed away, at the age of 77 years, at [illegible] this well-known and versatile practi- [illegible] s. Mr. McLeod became L.R.C.S. [illegible] in Hawick, whither he was racted by a severe cholera epidemic and where he ceeded to the practice of Dr. Wangler. He held the ices of medical officer of the burgh and to the workhouse many years. He was a certifying factory surgeon, geon to the police, parochial medical officer and ccinating officer to several parishes, and held several other pointments in the town. His jubilee of medical practice Hawick was celebrated in October, 1899, and he was then resented at a public banquet with a cheque and a silver a service subscribed for by over 400 friends and also ith a clock by his *confrères* in the medical profession. He ame originally from the Hebrides of Scotland, his mother eing one of the Campbells of Harris. He leaves a widow d a family of two who are grown up.

TRINITY COLLEGE, DUBLIN.—At examinations held in Michaelmas term the following candidates were successful:—

Final in Medicine.—Frederick F. C. Willington, Charles E. Moore, Harry R. Nelson, Richard C. Hallowes, Thomas C. A. Sweetnam, Thomas J. Crean, Herbert Stone, and Cecil J. Wyatt.

Section B.—Wright Mitchell, Henry M. Crawford, Arthur A. M'Neight, Wilfrid Thunder, Hugh Stewart, William J. M'Iver, Robertson S Smyth, Edward G. Scroope, Thomas Wilson, and John Chambré.

PRESENTATION TO A MEDICAL MAN.—Mr. R. Hamilton Ramsay, M.D., C M. Glasg., on attaining his eightieth birthday recently, was presented with an inscribed rose bowl by the committee and playing members of the Torquay Athletic Football Club, of which he has been president for 30 years, and with a framed photograph of the committee of the Sick Gardeners' Relief Fund, of which he is also president.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—During the year 12 new members were elected, three died, and three resigned, the number of members being 298 Two widows and six orphans applied for relief, three widows died, and one orphan became ineligible. At the end of the year 53 widows and 15 orphans were in receipt of half-yearly grants. A sum of £3299 10*s*. was distributed during the year and the expenses were £246. At Christmas a present was made to the widows and orphans amounting to £583.

DONATIONS AND BEQUESTS.—The Bolton Infirmary and Dispensary will benefit by the sum of £500 under the will of Miss A. Mason of Horwich, Lancaster.—By the will of Miss M. W. Nash of Cork £300 are bequeathed to the Home for Protestant Incurables at Cork and £200 to the Victoria Hospital for Women and Children at Cork.—Miss E. A. T. James of Edgbaston has under her will bequeathed £1000 to the General Hospital and a like sum to the Queen's Hospital, the Eye Hospital, the Blind Asylum, and the Deaf and Dumb Asylum, Birmingham. The Bayswater Hospital for Consumption, the Cancer Hospital, London, and the Putney Hospital for Incurables also each receive £1000 The Leamington Hospital for Incurables will receive £500—At the monthly meeting of the committee of the Plymouth Royal Eye Infirmary held on Dec 2nd it was reported that an anonymous donor had given £1000 to the infirmary.—The Middlesex Hospital has received a further donation of £125 from Mr. Charles Davis and also a further donation of £60 to the Cancer Fund from Miss Fanny M. Marriage.

ROYAL INSTITUTE OF PUBLIC HEALTH.—Congress of the Royal Institute of Public Health to at Folkestone, July 22nd to 27th, next year, ther a section for Child Study and School Hygiene. D Carpenter has been appointed London secretary Percy G. Lewis local secretary. Gentlemen de contributing papers should communicate with t secretary. Those wishing to attend the Congress, not members of the institute, can do so by t delegate's ticket, price £1 1*s*.

BEQUEST TO JOHNS HOPKINS UNIVE William Wyman, who died recently, has willed h valued at more than $500,000 (£100,000) to Johns University upon the death of his daughter. Mr. a year ago gave an estate in Baltimore to the sity, beginning the movement which resulted in ing a new institution and in the raising of $1 (£200,000) endowment fund The land then g Mr. Wyman was worth $250,000 (£50,000). Ther institution in America which is more deserving of than Johns Hopkins University. As a scientific is almost the equal of any in the world. The m which rich Americans give money for the advanc scientific research is an object lesson to Englis should result in lifting the United States to a v position in this line of work.

THE annual dinner of the Royal Fre pital and London School of Medicine for Women was Dec. 15th at the Hotel Cecil, Mrs. Garrett Anderson the chair. 300 persons sat down to the dinner an the guests were Sir William and Lady Broadbent, S Roberts, Sir Thomas Smith, Professor Tilden, Westlake, and Mrs. Henry Fawcett. After the Roy had been honoured Mrs. Anderson proposed as t of the evening "The Success of the School and t Free Hospital." She spoke of the movement higher education of women, of which medical e was only a part, and contrasted the gathe influential friends present at the dinner with h isolation 40 years ago when she was allowed in h student days to go to the Middlesex Hospital, part nurse, partly as a student, and to learn what she She had, she said, to meet the strong unspoken disa of almost everyone there, from the senior members staff to the scrubbing maids, and though in a she was able to understand the feeling of t the contempt of the scrubbing maids was hard Having then described her difficulty in finding an edu body to examine her for a degree or a diplom Anderson pointed to the quality of the work which being done by medical women in England who owed debt of gratitude to the Royal Free Hospital, which tion was in urgent need of financial assistance. M Barrow, senior surgeon to the hospital, and Mr. Stank senior lecturer to the school, responded to the toa Raymond Crawfurd then proposed the health o Guests," coupling with the toast the names of Sir Broadbent and Sir Thomas Smith. The secretaries dinner, Miss Douie, M.B., and Miss Crosfield, M.D., congratulated on the excellence of all their arrangem

Notes, Short Comments, and Answers to Correspondents.

THE LIGHT CURE AND ELECTRO-THERAPEUTIC INSTITUTE, LIMITED.

To the Editors of THE LANCET.

SIRS,—In justice to myself I am sure you will *accord me a little of* your valuable space in order to answer, as far at all events as I am concerned, *your severe criticism re* the above.

As the "brave man" referred to in your article on the subject, may *I explain that the original idea of the directors was to open an institute* where light baths especially could be obtained by the middle-classes at a fee commensurate with their purses and that I, having made a somewhat special study of this branch of electric therapy, was proposed as the medical officer of the institute. It was afterwards decided that other forms of electric therapy should be added to the work of the institute, but it was distinctly understood—and there is nothing in the prospectus to warrant any other construction—that no treatment was to be given without a prior consultation with the medical officer or unless the patient brought a prescription from his own medical attendant—that is to say, with the exception only of really healthy people who would take light baths as a luxury instead of the Turkish bath, the former of course being such a distinct advance on the latter. May I inform you.—

1. That before committing myself to the post I consulted a solicitor to one of the "defence unions" and that he was perfectly satisfied that there was no contravention of medical ethics in the matter.

2. I also consulted a well-known gentleman, one who is especially connected with questions of medical ethics. His reply was: "I see nothing unprofessional in the prospectus and wish that all these institutes were under medical supervision."

3. I failed myself to see anything "unprofessional" in my position any more than in the case where a medical man has an appointment to a hydropathic establishment, and, as you are aware, there are scores of medical men holding such appointments throughout the country.

strict medical control.

5. However, to be on the safe side I sent in my notice of withdrawal from the company before, by the bye, your issue of the 12th, and this because in order to make doubly sure my position I had also asked the advice of eminent and honoured friends in the profession, and most of these advised me in my own interest to resign as it was their opinion that such a position would not enhance my social or professional status. At the same time most of them admitted that the Medical Council would not cavil at the situation any more than in the case of the hydropathic practitioners mentioned.

6 *I even wrote to the Medical Council on the matter, though* naturally they could not give an opinion or even advise.

What could I have possibly done further? May I say, in conclusion, that to mention even the name of Mr. Ward in connexion with "quackery" is ungenerous to say the least. He bears an honoured *name, he is chairman—or has been—of the Harrogate Baths Committee,* he is a well-known *public* man, besides being an able and scientific electrician, and you can have but little knowledge of him, or of myself, or I am sure you would not have made such scathing criticisms as all my actions in the matter have been above board; further, because *I detest anonymity at all times, I beg to subscribe myself in* full,

Yours faithfully,

J. STENSON HOOKER, M.D. Durh., &c.

44, Gloucester place, W.

⁂ We publish Dr. Stenson Hooker's letter with pleasure. Personal knowledge of Dr. Hooker would not have assisted us in writing the article, for we had not the slightest conception of the identity of the medical man stated in the prospectus to have accepted office. We congratulate Dr. Hooker on his wise decision to retire from an *undertaking* connexion with which might have entailed trouble upon him. We do not say that it would have done so, any more than we have stigmatised the impending institution as fraudulent, or the late chairman of the Harrogate Baths Committee as a quack. We have said none of these things. We have criticised the prospectus *of the Light Cure* and Electro-Therapeutic Institute, believing that the undertaking might, for all that document showed to the contrary, be an undesirable one from a medical point of view. There was no guarantee in it that patients would *only* be treated upon medical recommendation. Dr. Hooker's view as to the necessity of such a *limitation being* set to the medical work of the institute is, we are glad to say, clearly the same as our own.—ED. L.

ANONYMOUS SLANDER.

A PERSON who signs himself "Minister of the Gospel" has addressed to the *Daily News* from Ramsgate a story of a local *surgeon* who operated for cataract upon an elderly female subject causing her great suffering and producing no good result. According to the reverend gentleman's story the surgeon said to him, "She will never recover her sight and I never thought she would, but I operated upon her just for a bit of practice." He asks, and appears to expect a negative reply, "Need I add a word to expose the brutality of the man?" The answer, of course, is that he certainly needs to add a word—in fact, several words. He needs to give the name and address of the surgeon in question. Our impression is that a "Minister of the Gospel" is an anonymous slanderer and we regret that this statement concerning him is deprived of the effect that it might otherwise possess by our being unable to look beneath his decent clerical veil.

THE VAGINAL DOUCHE.

To the Editors of The Lancet.

Sirs,—Even in making a general statement I should be sorry to be inaccurate. I have consulted a bulky and well-illustrated price list dated 1900, with a supplement dated 1901. The terminal opening in about half of the sketches is distinct, in three others there is, possibly, no opening, and the remainder are too indistinctly drawn to say anything about them. I refer to Messrs. Down Brothers' price list—one of the best, I presume. I have inquired at several chemists and at one large "stores." The one article sold is Higginson's, with gum-elastic pipe with small holes, *one at the apex.* Further inquiry elicited, twice, several odd pipes of different patterns, one or two closed at the point, but generally one of the several openings was in the centre We have, then, an instrument of faulty construction in general use, and we are told on authority that the fault has been recognised for many years, yet neither patient, nor medical man, nor retailer knew that a better make was to be had.

A very ingenious instrument was described and figured by Mr. Haydn Brown in The Lancet of Feb. 28th, 1903, p. 595 He rightly takes objection to the number of small openings which is usual. I hope medical men when prescribing lotions for vaginal use will take some trouble to advise their patients regarding the kind of instrument to get and the way to use it—that is if they believe with me that some untoward results *post* syringing are occasionally *propter* syringing.

I am, Sirs, yours faithfully,

Dec. 19th, 1903. G. Crichton.

THE THRIFT OF THE SALVATION ARMY.

To the Editors of The Lancet.

Sirs,—Mr. Griffin Wilkes has drawn attention in your columns, under this title, to one of the greatest evils in the work of the Salvation Army. While many of their "officers" travel first-class, and while some go on tour round the world or to America in luxury, the half-fed anæmic girls who carry articles for sale from door to door receive a miserable pittance, their local speakers frequently have a struggle to make ends meet, their typists and shorthand writers receive about half of what they would get elsewhere, and their maternity nurses are paid, I am told, £10 per annum.

Why should Mr. Coombs wish to know full particulars of the uterine functions of the female candidates for enlistment in the army? I should have thought it sufficient that the candidates were "strong and able for their work," without any particulars being given regarding their different organs. Inclosing my card,

I am, Sirs, yours faithfully,

Dec. 19th, 1903. M.D.

⁂ Mr. Coombs not being a medical man is not in a position to form a medical opinion as to the physique of young women from reading obstetric details concerning them. This sort of information might well be withheld from him.—Ed. L.

THE CORONER, THE PATHOLOGIST, AND THE GENERAL PRACTITIONER.

Mr. T. Launcelot Archer of Vincent-square, Westminster, was summoned by the police on Dec. 15th to see a woman found dead in her chair. Mr. Archer later (probably the next day but the letter is undated) received a communication from Mr. Troutbeck asking to have the circumstances bearing on the cause of death communicated to him. Mr. Archer very properly replied that if Mr. Troutbeck wanted his evidence he had ample legal powers to obtain it. On Dec. 17th Mr. Troutbeck replied that he could not understand Mr. Archer's letter, which he considered to be "founded on the misconception that information given to the coroner in preparation for an inquest is evidence. At the present moment I have no information whatever as to whether if a guinea is paid to you out of the rates for evidence you are in a position to give any information to justify that expense. Gentlemen who claim payment for giving expert evidence must first show that they have expert evidence to give." This, of course, is not the law, but Mr. Troutbeck's reading of the law, and Mr. Archer very properly replied that no information could be required from a medical man except expert evidence. Mr. Archer promptly repudiated the uncourteous and unfortunate suggestion that he was only looking for a fee. We understand that the inquest was held on Monday morning last, when Dr. Freyberger performed a post-mortem examination and found an enlarged heart and a full stomach. The case hardly seems to have been of such pathological rarity as to necessitate the withdrawal of the post-mortem examination from the medical man last in attendance.

A POINT IN SANITARY LEGISLATION IN INDIA.

To the Editors of The Lancet.

Sirs,—I have a patient in a family living in a suburb ten mi Bombay. In the immediate vicinity of their bungalow is a plot used for cultivation, yielding a certain annual revenue to C., besides being the means of subsistence to the owner himsel purposes of cultivation manure has to be employed, consisti large quantity of fish, of fat, and other refuse matters whic thrown on the soil give off a sickening odour, creating a n to the neighbours who seriously apprehend injury to their thereby. As this is a question affecting the public I am curious to know, Sirs, whether the aggrieved could secure any redress in court which to their satisfaction amount to nothing less than a complete prohibition by the cour cultivation of the adjacent plot of land. It would be interes learn if the court would really press such an order which effect would deprive an agriculturist of his only means of livelih himself and his family, to say nothing of the loss of a definite land revenue to Government, which counts a great deal agricultural country like India.

I should be so grateful, Sirs, if any of your readers intere sanitary law would oblige me with the necessary informatio for. I am, Sirs, yours faithful

Dec. 4th, 1903.

⁂ The matter is one for the opinion of a lawyer in India. In E such abuses can generally be abated by legal process.—Ed. L.

THE ACTION OF SULPHONAL.

To the Editors of The Lancet.

Sirs,—I should be glad to know from any of your readers observations have been made regarding the action of sulphonal mucous membrane of the gastro-intestinal tract.

I am, Sirs, yours faithfully,

Dec. 19th, 1903. B. B

A QUESTION OF FEES AT A CORONER'S INQUEST.

"Vexatus" writes:—

> "I should be obliged for your opinion on the following house surgeon at a small hospital and gives chloroform B, an honorary surgeon, operates on a child. The chil under the anæsthetic and as a result of it. The coroner to attend the post-mortem (on the heart only) and to give ev at the inquest, saying he leaves it open to B to refuse if he r A says he will be much obliged if B will be present a mortem and inquest. B is accordingly present at both. conclusion of the inquest the coroner gives B a cheque fo guineas, saying he leaves it to him to give A anything B thinks he (A) may deserve. Supposing B had been subp would he have been entitled to two guineas in fees? *If so,* s he give anything to A? As honorary surgeon should he di a coroner's fee. Should the coroner's evident wish carry private wish as to the disposal of public money."

We do not quite follow this story. There is no B should disclaim a coroner's fee as honorary surgeon and remark that he is lucky to get a fee at all for giving respect to a death that occurred in a public institution. coroner here exercises his discretion very properly and his indicated wish should carry weight.

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of The Lancet.

Sirs,—Should any of your readers contemplate purchasing a car, I would strongly recommend that they should obtain a *Automobile Club Journal* of Dec. 17th. I think they will is no pneumatic tyre in the market which is not calculated t largely to the worries and anxieties of professional life.

I am, Sirs, yours faithfully,

Stratford-on-Avon, Dec. 19th, 1903. Harry Lu

THE TREATMENT OF PEDICULI CAPITIS.

"E." asks for the advice of his brother practitioners in a case wh pediculi having been removed by the usual treatment the nits with unusual obstinacy. Methylated spirits, ether, and in quassia have all been used without any result.

EDITORIAL NOTICES.

s most important that communications relating to the rial business of THE LANCET should be addressed sively "TO THE EDITORS," and not in any case to any eman who may be supposed to be connected with the rial staff. It is urgently necessary that attention be to this notice.

especially requested that early intelligence of local events wing a medical interest, or which it is desirable to bring nder the notice of the profession, may be sent direct to is office.

tres, original articles, and reports should be written on ne side of the paper only, AND WHEN ACCOMPANIED Y BLOCKS IT IS REQUESTED THAT THE NAME OF THE UTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD E WRITTEN ON THE BLOCKS TO *FACILITATE IDENTI*-ICATION.

Letters, whether intended for insertion [illegible]

t [illegible]

t [illegible]

We [illegible]

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1903, which is completed with the issue of to-day, will be given in the next number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s* 3*d*.

To be obtained on application to the Manager, accompanied by *remittance*.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! *Subscriptions paid to London or to local newsagents (with* none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to *the Agent to whom the subscription is paid, and not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		[illegible]
One Year	£1 12 6	[illegible]
Six Months	0 16 3	[illegible]
Three Months	0 8 2	[illegible]

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the [illegible]

The Manager [illegible] the Offices to pl[illegible] *the weight of any of the copies so supplied.* Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *Poor law Officers' Journal, Eastern Morning News, Westminster Gazette, Sussex Daily News, Dublin Times, Birmingham Post, Surrey Advertiser, Notts Guardian, Dublin Express, Bradford Observer, Hereford Mercury, Sanitary Record,* [illegible] &c.
